Editorial.

ON THE BASIS of the rate of production for the first half of the year, the output of pig iron in the United States for 1906 should be 25,000,000 tons. This compares with 22,992,380 tons in 1905 and 16,497,033 tons in 1904. The market for pig iron continues to be steady and so long as this barometer of industrial activity marks fair weather, we may expect a continuance of national prosperity.

MINING MEN are always glad to hear of rich ore being found at great depth. The New Chum Railway mine at Bendigo, in Australia, is driving a new level at 4,262 feet vertically below the surface. In the neighboring Victoria Quartz mine the shaft is being completed between 4,154 feet and 4,254 feet. This news ought to cheer the prospector in Nevada who has just struck it rich at grass-roots.

OUR ESTEEMED CONTEMPORARY, *The Mining Record*, of British Columbia, makes a complaint that the Canadian Mining Institute neglects the interests of Western Canada, and more particularly British Columbia, which produces one-third of the mineral output of the Dominion. We, who also dwell on the Pacific, might similarly complain of the American Institute of Mining Engineers, when so large a part of its transactions are devoted to iron and coal, but we do *not* complain because, as our contemporary states, the American Institute does give the Western men generous representation in the Council and encourages the submission of papers dealing with subjects of interest to them. It might be well for the Canadian Mining Institute to adopt a similar policy.

THE COST OF PRODUCING COPPER is often under-stated, through omission to include the expenses of shipping, refining, and selling. In estimating profits, the cost per pound of converter bars at some railroad points in the West is quoted against the market price of the fine metal, as a measure of the success anticipated for a new enterprise. The cost of refining copper on large contracts is \$15 per ton and, allowing for the usual deductions, it averages \$18 to \$20 per ton in most cases; this is equal to nine-tenths of a cent per pound. If to this are added the freight to New York, the charges of the selling agents and other small deductions, the total expenditure in marketing converter bars reaches 1½ to 1¾ cents per pound. Those about to start new enterprises are apt to quote the costs prevailing among large mines with an established production, overlooking the fact that the treatment charges are always less to mine owners who are able to assure a steady output. To companies in the youthful stage, the cost of marketing unrefined copper is fully two cents per pound.

Our Motto.

A good wine needs no bush and a suitable motto should require no explanation. Nevertheless, it seems fitting at this time to give reasons for the faith that is in us. "Science has no enemy save the ignorant." It is a true saying and worthy of all acceptance. Time was when the mariner cut down the oak and made him a vessel wherewith to cruise the seven seas; he depended upon the fickle wind to propel his ship and he steered by the light of the stars. As he fared forth across the main and began to make traffic over the waste of waters, he found the need of something stronger than the old wooden boat, something more certain than the stars. His brothers took the iron from the earth and gave him steel to sheathe his ship, they dug the coal from which he drew the throbbing energy that furrowed the wave, they made him a compass whose trusty finger should point a path when the storm curtailed every star. Navigation became a science and naval construction an art. So also to those who go down to the mine in skips; to them Science gave tools, energy and a light wherewith to illuminate the dark places in the earth. The simple digging of ore was well enough so long as the miner did not penetrate far from the daylight, using pick and spade to move the mineral, applying his muscle to carrying the product of his toil and the sight of the ore as the guide to his advancement. But as he burrowed farther, these simple ways did not suffice, he harnessed the horse to his windlass and made a whim, he yoked the oxen to the cart that carried his ore, he compelled the torrent to turn a wheel and drain his hole in the ground. Then, penetrating to a depth greater than the height of the tallest trees, he found simple mechanical methods began to fail, he called on Science for help, for further he could not go alone. Aid was given abundantly. Steam replaced muscle, steel replaced wood, and engineering took the place of rule of thumb. Far from the day-light he penetrated into the adamant heart of the earth, until he walked in galleries a mile beneath his dwelling.

But even that was only a beginning. Science sharpened his tools with the diamond and quickened his operations with electricity. And then with faithful hand and trusty word, she told the miner how to separate the waste rock from the valuable mineral, the dross from the metal. Metallurgy became an art. Nor was this the end, Science did more; in every department of his manifold operations she breathed a system which crystallized into a great industry, orderly as the arrangement of a crystal, smooth as the working of a machine. The prospector became a geologist, the miner became an engineer, the hole in the ground became the basis of a business that supported a vast community. And yet the story is not told, for Science became more than an aid to work, she became a companion in pleasure, a guide, a philosopher, and friend. As the piece of ore is converted to burnished silver, so the old common sense was transmuted to a trained intelligence ready to cope with every problem in life. Man went forth to conquer, first nature and then himself. Self-reverence, self-knowledge and self-control led him to sovereign power. Therefore, as a child

to its mother, as a patriot to his native land, so he who mines the ore, who wins the gold, refines the silver or smelts the lead, turns to the fairy who has blessed his going forth and his coming home; he honors her ways, which are ways of truth, he follows her light, which suffers no eclipse; and to those that follow he says, "With this sign shalt thou conquer: 'Science has no enemy save the ignorant.'"

Postal Facilities.

A deputation waited on the Postmaster General of Great Britain, during the current week, to urge the Government to open negotiations for penny postage with the United States. By an arrangement already made and to go into effect on January 1, 1907, the international postal rate is to be five cents, not per half-ounce, as at present, but on the full ounce. This tendency to decrease the cost of postal rates is important; it facilitates business and promotes civilization, for it is obvious that the more frequent communication between people living in different countries tends to soften asperities and to promote good understanding, as nothing else can do. From a business standpoint, the lessening of the rate on an ounce letter will bring relief, especially to our English friends, who complain, not without reason, of the large number of American letters on which they have to pay because of insufficient stamps. As the half-ounce regulation allows only of one sheet of such business letter-paper as is used in America and as it is not the custom to provide special paper on thin envelopes for foreign correspondence, as they do in England, the limit of weight is often exceeded. In any event, the cost of 10 cents for a letter of ordinary length is a heavy tax. The removal of it will be acceptable. Penny postage with the British Empire would be a great boon, but it seems a good deal to expect. Certainly, it would be a decided help to an enlargement of business between the Anglo-Celtic peoples. We shall have it some day, inevitably, and we can afford to appreciate the initiative of the English in this regard, for from the days of Rowland Hill, to whom the British domestic penny postage is due, they have led the world in improving and cheapening the facilities for correspondence.

In this connection, it may be stated that our London letter takes 12 to 13 days to reach us, our Johannesburg correspondent's letter arrives here regularly in 30 days, and recently a letter even from Bulawayo, in Rhodesia, reached us in 31 days. From Melbourne and Sydney we hear within three weeks. We can communicate with New York in four days and with Denver in two. With Alaska and Mexico communication is less regular, but Dawson can be reached in eight, and Mexico City within five days. Thus are the ties of interest and the bonds of business drawn together. Ten years ago a mining paper at San Francisco was handicapped by the time consumed in the transmission of news from the more distant mining centres of the world. Today it is not. Fast trains and steamers, together with the telegraphic wires that link us to far-away mining communities, enable us to hear promptly what others are doing, while living in the midst of a community that does something itself in mining and metallurgy.

By the Way.

In a lecture delivered at Columbia University and published in *The School of Mines Quarterly*, Professor Wilhelm Ostwald, of Leipzig, explained certain fundamental ideas in a luminous manner. He said:

The general chemical facts, which we call oxidation and reduction in our times, were recognized and brought into scientific comprehension during the eighteenth century. It was known, for example, that just the same substance which is formed by the burning of charcoal in the air could be formed by mixing the charcoal with certain substances, litharge, for example, and heating the mixture; the litharge would be reduced to metallic lead and the charcoal would disappear, just as it disappeared in burning in air. On the other hand, metallic lead would be changed into litharge by heating it in contact with air. In a similar way different substances could be burned and then brought back to their former condition by heating them with a more combustible substance. In such a way the general idea of reduction and oxidation was formed long before oxygen as a substance by itself was known. To get a comprehensive view of all these facts the theory of phlogiston was invented. According to this the change of properties and the evolution of light and heat during combustion were all connected with the existence of a certain element called phlogiston. If a substance burned, a flame generally appeared, and it was assumed that phlogiston passed away from the substance during combustion. Then it was assumed that in the process of reduction the former properties were restored to this substance by uniting it with phlogiston. This gave quite a comprehensive theory of combustion, as you are aware, with one false assumption.

Instead of assuming that the product of combustion is the result, as we now know, of an addition of oxygen to some element, it was assumed that something, namely, phlogiston, had disappeared. It was quite natural to assume this, because by observing the combustion of such substances as wood, coal, charcoal, etc., the disappearing of something was obvious. We now know that the disappearing substance changed into invisible gases, but in those days it was natural to assume that combustion was not connected with the addition of something, but with the disappearance of something, and this something they called phlogiston. We must therefore look upon the phlogiston theory not as sheer nonsense, but as the result of an entirely logical generalization, combined only with one mistake, which was discovered later by actual measurements. But exact measurements are dependent upon the progress of science. Everything begins with rough observation; after the fact is known in a rough way closer investigation begins.

Now, the oxygen theory as developed by Lavoisier accepted a very large part of the old phlogiston theory, namely, a general idea of combustion and reduction; it only explained that combustion means the union with oxygen; and reduction, the separation from oxygen.

The oxygen theory of combustion proved more satisfactory than the old phlogiston theory, because oxygen was a substance known, investigated, and measured; in short, was recognized as a chemical element, a kind of matter, while phlogiston existed only in a theoretical way as a property like the Aristotelian elements. It was impossible to get phlogiston in a bottle and employ it for scientific investigation, while it was possible to do this with oxygen.

This great change was brought about, as I have mentioned already, by the discovery of another law, which was known in its rudiments long before, but which was expressed clearly by Lavoisier, that is, the law of the conservation of weight. This law means that if we take

a certain amount of matter (we use this term still, because everyone thinks he knows what matter is), and enclose it in some way so that nothing can be lost, we do not know of any change which may occur in this mass of matter which would cause a change in its total weight. Even if there is a chemical change occurring, this matter will not alter its weight, although some substances may disappear during this process and others may be formed. It is not self-evident to assume, for instance, that by changing solid sulphur and gaseous oxygen into gaseous sulphur dioxide no change in the total weight will occur. There was no necessary connection known between weight and chemical change; for just as the other properties of matter are changed by chemical combination, the weight also might change. Indeed, there was every possibility that a change in weight might occur. It was so little impossible that a most distinguished chemist, Professor Landolt, of Berlin, sacrificed fifteen years of his scientific life to investigate this very question, that is, whether there is any change of weight connected with chemical weight, with the result that he could discover in most cases a slight diminution in weight. He is not quite sure if the diminution is really connected with the chemical process, but he has observed it. This is just the point of this most difficult and refined investigation, to tell if the diminution is real and connected with every chemical change, or dependent upon some incidental circumstances. So you see that the conservation of weight is by no means a self-evident proposition. Self-evident things are things which we do not take care to investigate closely, and it was simply a scientific question whether in chemical combinations there is a large change in weight, a small change, or no change at all.

Therefore it was an important discovery to show that in a great number of cases no appreciable change in weight occurs. And Lavoisier by using the balance secured a very simple means for defining an element. If we start with a certain amount of a certain substance, and bring about a chemical change of any kind, and then ascertain in what wise the weight has changed, we shall observe one of three possible cases: either the weight has diminished, the weight has increased, or the weight has remained unchanged. If the weight has diminished, the fact can be explained on the basis of the law of conservation of weight, only by the assumption that something has gone away, for example, a gas, and that therefore our substance was a compound one. To give an instance: If we heat mercury oxide, and change it into mercury, and find there is a certain loss of weight connected with this change, we must conclude that some substance has gone away from the mercury oxide, and therefore the mercury oxide is certainly a compound of mercury. Mercury itself may be an element, but this is not yet proved. We will first have to investigate all the possible changes of mercury, and if we find that all possible changes of the mercury are connected with an increase of weight, then we may define mercury as an element.

On the basis of the law of the conservation of weight, we can therefore define an element, and this has practically been done since Lavoisier. An element is any substance which can be changed into another substance only by increasing in weight, inversely, a compound is every substance which can be changed into another substance with a decrease in weight, depending of course on the additional fact that some other substance has been formed at the same time. This is a definition of an element which you will find in those text-books which are more carefully written than the ordinary text-books are. In ordinary text-books I do not think you will find any experimental definition of an element, for the writers assume in a general way that everybody knows what an element is, or define it by the help of the hypothetical atoms.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

IN cutting rubber for gaskets, etc., have a dish of water handy and keep wetting the blade of the knife. It makes the work much easier.

TO FIND OUT whether a plate is burned or crystallized, cut a thin chip for the distance of an inch or so with a thin sharp chisel. If the chip curls up the iron is good.

WHEN driving out bolts, where you have no protection for the thread, strike the hardest blow you can give with a heavy hammer. Light blows with a small hammer will upset or rivet the bolt-ends.

TO PREVENT lamp chimneys from easily breaking, put them in a pot of cold water over the fire, and add some common table salt. Boil well and let cool slowly, then take out the chimneys and wash them well.

TO CLEAN varnished paint-work make up a solution by boiling spent tea-leaves in water, and apply this hot with a soft piece of flannel, always rubbing one way. Rub dry with a soft cloth or with clean white waste.

TO CLEAN smoky chimneys, dilute a teaspoonful of sulphuric acid (oil of vitriol) with five or six times its bulk of water. Dip into the solution a piece of flannel tied to a stick and draw the flannel through the chimney, then rinse in water and wipe dry.

THE centre of percussion in a moving body is that point which would strike an opposing body with greater force than any other point. If the opposing body is immovable, it will receive all the force of a rigid moving body which strikes with its centre of percussion.

TO DRILL holes in glass, use a common steel drill, well made and well tempered. The steel should be forged at a low temperature, so as to be sure not to burn it, and then tempered in a bath of salt water (brine solution) which has been well boiled. Such a drill will go through glass rapidly if kept well moistened with turpentine in which camphor has been dissolved.

TO KEEP machinery from rusting, take one ounce of camphor, dissolve in one pound of melted lard, take off the scum which forms, and mix in as much powdered plum-bago or black-lead as will give it an iron color. Clean the machinery and smear it with this mixture. After 24 hours rub clean with a soft linen cloth. It will keep clean for months under ordinary circumstances.

TO CUT a glass tube, for example, a glass gauge-tube, saw it two or three times lightly with a wetted three-cornered saw-file and it will mark or nick the glass. Now take the tube in both hands, both thumbs being on the opposite side from the mark and about an inch apart, then try to bend the glass, using the thumbs as fulcrums, and it will break at the mark where it has weakened the tube.

WHEN mixing various metals, melt the one having the highest melting point first, and then add the others in the order of their melting points, heating them first to prevent their chilling the metal already melted, and stir them with a wooden rod. Should the metals tend to volatilize, or to form an oxide, keep the surface covered with a layer of fine charcoal. Be sure to skim the surface of the metal carefully before pouring.

EFFECTS of freezing on quick-setting portland cement mortar: Numerous experiments have shown that such mortar is not injured, provided it is not frozen, until 12 hours after it is placed, and that it is kept frozen until set. If a one-half per cent salt solution is used for mixing the mortar no injury results from freezing. Hot water hastens the setting of portland cement mortar, at the same time retarding the freezing.

CHILLING, chill-hardening or chill-casting gives great hardness to the outside of cast-iron, by pouring it into a mould made of iron instead of sand. The iron causes the outside, or skin of the casting, to cool very rapidly, and this, for some unknown reason, increases its hardness. The process is frequently confounded with case-hardening, which consists in converting the outer surface into steel, by heating it while in contact with charcoal or potassium cyanide.

TO REPAIR a water pipe, mix a moderately stiff putty from red and white-lead in boiled linseed oil, and work into it some hemp chopped into short lengths. Lay it over the crack in a moderately thick mass. Wrap it tightly around the pipe with some strips of canvas, in so doing overlapping both ends of the crack; and finish by serving, or closely winding it, with marline (small hemp cord of two strands loosely twisted). If the pipe is found to be worn thin, or is full of holes, bend a piece of thin sheet-copper or tin to the round of the pipe over the putty, then put on canvas, and serve or wrap with marline as before directed.

A REVERBERATORY FURNACE is a structure of refractory materials, so designed that it can be economically heated to a sufficiently high temperature throughout a hearth of large dimensions. In general four conditions must be satisfied: High temperature, economy of fuel and labor, suitable dimensions, and design suited to its particular use. In addition, such a furnace may be required to give alternately a high or a low temperature, as in a re-heating furnace or in a lead-smelting reverberatory; again it may have to give simultaneously different temperatures at different parts of the hearth, as in a glass-furnace or a roasting-furnace; or, once more, different temperatures in different compartments, as in the Hofmann furnace for bricks and pottery ware.

THE management of a concentrating mill or stamp mill: The secret of success in running a concentration mill lies much in procuring a well-trained and competent man to take charge of it, for the business requires as much education and skill as needed in the reduction of ores. E. H. Davies, in his recent work on 'Machinery for Metalliferous Mines,' says: "I have known a case in which a first-class modern concentrating plant, for treating lead and blende ores, was entrusted to a man whose only knowledge of engineering was in connection with steamers and marine engines. Needless to say, failure resulted, and the tailing was as rich as the crude ore. In another case, I knew of a first mate of a steamer being put in charge of a gold mine and mill, with a result which may be anticipated. It is just as necessary to put fully qualified medical men in charge of a hospital; though the grave error of putting amateurs, or relatives of directors of a mining company, to look after the most costly and intricate machinery is continually being made."

DISTINCTION between 'dead' and 'live' load: Dead load is that which is applied gradually, as the weight of the structure itself. A live load is one applied suddenly, or accompanied by vibrations, as that of a train traversing a bridge, or the force exerted in a moving machine. The effect of a live load is twice as severe as that of a dead one of the same weight. Hence, a structure, designed to support a live load, should have a factor of safety twice as large as the one used for a dead load. The load of a crowd of people walking on a floor may be considered to be a mean between that of a dead and a live load. In laws relating to the loads on floors, the weight, outside of structure and fixtures, is referred to as live load, no matter of what it consists, but, in that case, it has not the significance given by engineers, as above defined. The building code of Greater New York specifies the following as the maximum permissible loads for different soils: Soft clay, one ton per sq. ft. Ordinary clay and sand together in layers, wet and springy, two tons per sq. ft. Loam, clay or fine sand, firm and dry, three tons per sq. ft. Very firm coarse sand, stiff gravel, or hard clay, four tons per square foot.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Large vs. Small Machine-Drills.

The Editor:

Sir—There has been much discussion of late relative to the comparative cost of the various methods of mining. This is a subject of much interest and importance in view of the fact that the adoption of some certain method which may be particularly applicable to peculiar conditions may represent the difference between operating at a profit and losing money. Even when no actual loss occurs and where a profit may be had, it is still the aim of the management to make that profit as large as possible. This is accomplished by close attention to details, and the adoption of those methods of working best suited to actual conditions. It is an unwise policy to work along a certain line simply because it has been satisfactory at some other mine, for a system that may be eminently successful at the Big Bonanza mine in Colorado might entail certain disaster if installed at the Tight Scratching property in the next State or even in an adjoining township. This argument will, I think, hold good in a general way whether we are considering a reduction-plant or a power-drill.

There are men today who contend that for fast work and general satisfaction—not to say a minimum cost—the larger type of drilling machine is to be preferred to the one of smaller calibre. Personally I find that this is only true to a rather limited extent. While I can only speak in this regard in a general way, having no available data of my own, I would draw the attention of the reader to the paper of F. T. Williams, dealing with this subject and published in Bulletin No. 8 of the American Institute of Mining Engineers. This paper gives us the result of an exhaustive comparative test between a large and a small machine.

The chief item wherein a saving was made by the 21-in. drill over the 3½-in. machine was in operating expenses, which were 50% less or one-half; and the total cost of the cross-cut in which the small machine was used was just 27% of that driven by the bigger one. In this test it appears that the conditions were identical. The ground was Pikes Peak granite, coarsely porphyritic; this doubtless was good drilling ground. Then a highly indurated andesite, or phonolitic breccia was tried; this rock was unquestionably hard and very likely was inclined to drill uneven on account of its brecciated nature. Then with true massive andesite, trachytic phonolite and other rocks of a similar character, rock was encountered that called for steady pounding on the part of the drill. The comparison showed that the small machine accomplished about 88% of the work done by the larger at a cost of 27% less. This work was done on the sill-floor. If a test were to be made in all-round mining, I believe it would show results even more favorable to the small machine.

There is no doubt but what there are certain conditions under which it would be desirable to use only the larger size, as in shafts or a drift where it would require the whole shift in order to rig up, drill the round, and blast. It will be found, however, that in ground of average hardness, permitting of a reasonably straight hole, it will be a great advantage to use a machine that one man can operate. If everything is as it should be, the face clear of broken rock and the machine and accessories in good order, the machine man can go on shift, drill his round, and blast on quitting. In the case of the larger drill, under similar conditions, the men will drill the round and if they get

through early they cannot blast as a rule until quitting time, or if they do the smoke will prevent them from doing anything more at that point. Of course, if there are two or more places to use the drill, it will be otherwise, but that is not often the case. Therefore, in the case of the one man and small machine, he gets in his round of holes and blasts; in the other case, the two men do practically the same thing and no more. The first cost, labor expense and air-consumption are decidedly in favor of the smaller machine.

It will be claimed that the larger machine will drill a longer hole and, as it calls for larger steel, the hole will be of greater diameter, thus permitting of more powder at the bottom. As to the length of hole, it will be found that the smaller drill will handle a hole deep enough for practical purposes in a drift. It is a poor machine that will not put in a hole five feet if the drill is kept clear in the hole; many of the crooked holes are merely the result from inattention on the part of the operator. A little good judgment at the right moment will, in almost every case, prevent 'fitching' in machine drilling as well as drilling by hand. Many a hole has been bottomed after it has shown a disposition to 'fitcher' by swinging the machine and running on as short a stroke as possible. The intelligent miner is ever quick to avail himself of every little knack that he finds is of benefit to him.

Some men think a large machine will force the bit through a slip which would put a small machine out of business. Let us observe two hand-drillers at work. The drill starts sliding to one side of the hole. One of them, a big, husky fellow with a No. 6 hat and No. 11 shoes keeps on pounding the drill with trip-hammer blows and trying to twist the drill, which by this time is 'stuck.' He then curses the drill, throws down the hammer and may-be his hat and gives utterance to language which, if printed, would be unavailable. One sensible man on the other hole, when he finds the bit commencing to slide, holds it toward the slip and, when he feels it to be in the right position, taps the head of the drill a few light blows and, as a rule, manages to square the end of the hole and keep right on drilling. These same arguments are applicable to machine-drilling.

There is more logic than poetry in the adage of the Cousin Jack that "They that can't schemey must lous-ter." Now, as to the other contention in favor of the larger machine, that it drills a larger hole, thereby allowing a greater amount of powder to be placed near the bottom, etc. That the nearer the powder is to the bottom of the hole the more effective it becomes, no miner will deny, but it is questionable if this advantage, gained in this way is sufficient to pay for the greater cost of the larger hole. I never hear this argument advanced but I think of an incident that occurred at one time in British Columbia. A certain corporation was driving a tunnel to serve as an aqueduct. The rock was a hard quartzite and, beside being hard to drill, it would not break well. During one of the visits of the consulting engineer the nature of the ground was brought to his attention and the fact of its being hard to drill and mean to break. When asked for a suggestion in that regard he gave it as his opinion that the proper thing to do was to make the drill-bits bigger so that a larger hole would be made and the charge placed nearer the bottom of the hole. When this idea was communicated to the man in charge of the work he laconically observed that it might be still better to make one good big bit the size of the tunnel and bore it all out and thus save the cost of the powder.

There is a point at which the economical limit is reached in the size of the drill-bit. When this point is passed it would doubtless be better, if the explosive does not act to advantage, to chamber the holes with a light charge

first, then blow or scrape out the loose dirt and place the full charge. This is, of course, objectionable on account of the gas created, but this is not great and can be reduced by blowing for a few minutes.

It is frequently the case that the 'cut' holes are not given the inclination necessary for good work; sometimes an extra hole, judiciously placed, will make a great difference in the breaking of the round. Whenever circumstances will admit, the 'cut' holes should be fired alone; if they fail to explode or do not bring the ground, the other holes will not have been fired in vain.

The question of drilling and breaking ground is only one of the things which have to be considered in the operation of a mine and which tend to increase or decrease mining costs, depending on whether or not the best system applicable to the conditions is employed to the best advantage. It would be rank foolishness to use a power-drill in certain kinds of ground, while in ground that is

rock unnecessarily, sometimes accompanied by a set or two of timbers. Then after a while the timbers, owing to the shattered condition of the surrounding rock, commence get out of alignment and it requires constant attention to keep the shaft in shape. Frequent shut-downs are the direct result of speedy sinking, and the cost of maintenance, together with the loss of time required for repairs would seem to indicate that the "get there quick" policy may after all have some very serious draw-backs.

Butte, June 7, 1906.

EDWARD W. RALPH.

ALUMINUM PATENTS.—On April 2, 1906, the patent of Charles M. Hall on a process for making aluminum expired. This patent was granted to Mr. Hall on April 2, 1899. It protected the use of an electrolyte composed of cryolite as a solvent for bauxite, and one of its special features of value is that it possesses the important property of being easily fusible. Charles M. Hall is con-

Central Park and Albesu Theatre, Havana.

hard to drill and does not break well, so as to require a whole shift to drill the number of holes necessary, it may be advisable to use a two-man machine. For average ground, however, it will, I think, be found far more economical to use the one-man type. The miner will have to be entirely self-reliant, and, being left to his own devices, he will exercise his best judgment.

In development work, if speed alone is to be considered, there is no question but what the large-size drill should be used, but it may prove a short-sighted policy to sacrifice else everything for the sake of a few feet of additional opening per month. Many of our large shafts bear witness to this. They have been sunk with the largest drills, the holes filled with explosive and when the explosions have taken place the result has been very much as though a small earthquake had occurred. The orders have been: "Fill her with holes, give them plenty of powder and don't be afraid of making lots of room." One immediate result is the removal of a large amount of

nected with the Pittsburg Reduction Co. of Niagara Falls, and the patent has given the Pittsburg Reduction Co. a practical monopoly of the manufacture of aluminum in the country. While the Hall patent has expired, it is stated at Niagara Falls that the method of operation of the Pittsburg Reduction Co. is still protected by the patent granted to Mr. Bradley, one of the early pioneer workers in the aluminum field, and which does not expire until February 2, 1909.

WHERE a water-blast is used in mine ventilation its efficiency is nearly proportional to the height and volume of the column of falling water. A fall of 30 ft. gives a fair amount of air, but the same amount of water falling 100 ft. affords a much larger volume of air and it will issue from the air-water column with greatly increased velocity, enabling the air current to travel along a greater distance in the mine or to ventilate a greater part of the workings.

Three Weeks in Mexico. ---I.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

The tide was sweeping down the channel as the *Seguranca* left her berth at the Brooklyn wharf and swung into the East river. It was a clear sunny morning early in October and the great harbor of New York looked its very best. To the sound of many whistles our steamship threaded her way among the ferry-boats and barges that congregate where, off Governor's Island, the estuary separating Long Island from Manhattan meets the waters of the Hudson. As we passed between Fort William and the Statue of Liberty the broken sky-line of New York City stood silhouetted against the sky. There was just enough smoke to soften the outlines of the serrated pile of lofty buildings that, like a Titan's stronghold, guard the great waterway. Knowing the manifold activities that have created the island city, I felt the impressiveness, rather than the poetry, of the scene. Even such smoke as came from the tall towers of steel and stone, called,

presented even by the undeveloped New York of that day, and seeing the yellow dome of the *World* building, which for so long dominated the high roofs of the city, he exclaimed that in approaching the shores of other lands, the first thing to be seen was a church-steeple, but that here, emblematic of the unshackled thought of a new country, the first to catch the eye was the tower of a newspaper. If he had only known for what literary sewage that yellow dome stood sentry, he, though an agnostic, would have longed to see the old-fashioned landmark. Trinity steeple is dwarfed by the Empire building, but, thank the Lord, the dome of the *World* building is hidden by several recent monuments to the growth of our steel industry. Yet, as the city is left in our wake, growing dim amid its thin veil of smoke, the brutality of the crowds at Brooklyn bridge, the foul air of the Subway, the merciless sandbagging of Wall street, and the putrid politics of Tammany, are forgotten in the beauty of the harbor and the splendor of its life. Approaching The Narrows, between Staten Island and Long Island, the white hulls of the battleships at anchor off St. George, the

C O

New York City, from the Harbor.

with grim humor, the 'sky-scrappers,' seemed, not the incense rising from a peaceful cottage, but the murk of battle, the confused black fog of complex strife. Despite her higher mental activities and benevolent endeavors, New York, rising proudly by the waters that made her a great seaport, is the expression in stone of a relentless materialism, a predatory finance and a reckless luxury of life. Even the statue of Liberty, with her bronze oxidized to green and her guano-crowned head, has the air more of an old woman holding aloft a hot penny to incite a scramble among the awaiting larrikin, than of the representative of a freedom long since changed to license. As the *Seguranca* turned into mid-channel we could see the dark canyon of Broadway and the series of splendid structures that line its sunless depth. Trinity Church is no longer to be seen, it is obscured by a 23-story skyscraper where congregate daily a group of men capable of running a continent—and they do their best. The financiers look down upon, and over, the spire of Trinity—in more senses than one. When Huxley came to America, in 1876, he, like all visitors, was impressed with the scene

swift passage of a handsome yacht, the slow procession of barges crossing to Brooklyn, the stately sailing ships preparing for a long voyage, and the majestic movement of a huge Atlantic liner coming to port, all emphasize the multiplicity of a throbbing life, the pulsations of which are felt the world over. And so, farewell, thou Empress City of the New World, thou hast the respect that comes to those that have power and the admiration that is due those that are magnificent, but if thou dost not win the love that comes from kindly deeds and homely service, thou reckest not. Men may come and men may go, so long as steel is strong and gold is good!

It was four days to Havana. The port is guarded by the Morro, a castellated fort standing on a promontory to the left of the entrance. During the late Spanish-American war, Morro castle was often busy, but it did no execution until the very last day; in fact, after the armistice had been signed at Porto Rico. On that solitary occasion a shell went through the *New Orleans*, a cruiser, from stern to bow, between decks, killing no one, but playing sad havoc with the officers' quarters. Within

the harbor, one is still reminded of the late unpleasantness by the remains of the sunken battleship *Maine*. The military mast and a portion of the 'strong-backs,' or iron superstructure, project above the water. To them I saw attached a metallic wreath on which was inscribed "Memori Missouri," evidently placed there by the men of another battleship. The *Maine* was blown up on February 16, 1898, and I recollect the stir it made in distant lands, for on that day I happened to be at Cairo, in Egypt, where everyone in the Anglo-American colony confidently accepted the tragedy as the forerunner of war. There have been many discussions as to the responsibility for the crime, but it is generally accepted among the well-informed that it rests upon the *partido revolucionario*, the revolutionary party in Cuba, whose object it was to embroil the United States in war with the Spanish Government. How well they succeeded, all the world knows.

I shall not try to give any account of Cuba, even at second hand, for is it not told, and told well, by Robert T. Hill, whose 'Cuba and Porto Rico' is a monument to his insight and industry. Cuba is a lovely island, about the size of New York State, with every acre covered by good soil and possessing a variety of economic resources. Only 10% of the island is cultivated; in the valleys of the western hill-country is grown the tobacco which has done so much to soothe mankind, to express the courtesy of the civilized and to promote the friendship of the thoughtful. Naturally, I went to a cigar factory and bought some real Havana cigars on the spot, fresh from the making. In a large room about a hundred men sat in rows before small tables, like school-boys' desks. They were wrapping the tobacco leaf into cigar form. As they worked, a man standing on a stool read to them from the daily paper; he read dramatically and well, the purpose being to keep the workers interested. The proprietors of such establishments encourage this practice, which is general, because the men do not talk while the reading proceeds. When a Spaniard talks he uses his hands in gesture, hence he cannot employ them in labor; therefore the reading encourages efficiency. The men pay 10 cents per week from their wages (\$3 per day) to the reader, who, in large establishments, makes as much as \$125 per month.

Most travelers have spoken of the unhealthiness of Havana, of the dirt and filth that force their contrast with its beauty and color. Whatever criticism may be passed, by an unfriendly historian, on the American interference with Cuban affairs, it is certain that the sanitary measures undertaken after the war have wrought wonderful improvement. Garcia, Palma, even Sampson and Schley, were great men, but greater than these were George Waring and Leonard Wood, who did more for civilization than the leaders of war. And theirs was a contest with dangers as great as come to those on the battlefield, for Waring died, the victim of the yellow fever which he almost eradicated.

But Havana interested me most as a link in the story of Spanish conquest. Hernando Cortez, after outfitting at Santiago, called at the port of Havana before starting upon his great quest, on February 10, 1519. His fleet consisted of eleven vessels, more than half of them open brigantines, and the biggest not to be rated at over 100 tons. Thence he went to the coast of Yucatan, making a halt at the island of Cozumel, before proceeding to the mainland of Mexico, and landing at Vera Cruz on April 21. We followed nearly in this course, for from Havana we went to Progreso, the port of Merida, which is the chief city of Yucatan, and from there we also went to Vera Cruz, on our way—as did Cortez—to Mexico City. The parallel served to emphasize the difference. Cortez and his buccaneers went through uncharted seas and to a land they knew only by rumor; to them the West was

full of an unlocked mystery and the place of untold gold; to us there was keen interest and expectation also, but it was an interest toned by experience and an expectation limited by knowledge. However, even the *conquistadores* can have had no more discomfort or have used language more picturesque than the passengers of the *Seguranea* when we lay off Progreso for three days at the mercy of a 'norther,' or north wind, which prevented the captain from unloading his cargo or coming to anchor. Progreso is an open roadstead, and when the north wind blows, the lighters that transship the cargo of the larger steamers are afraid to leave the shelter of the wharf; hence wearisome delays such as ours. And when the sea calmed it was painful to watch the unintelligent manner in which unloading proceeded. Among other consignments there was one of 40,000 bricks; the passengers, eager to see the steamer on her way, watching the wretched *peons* removing this cargo from the hold, suffered with an impatience only to be surpassed by the mortification of the consignee who must have paid heavily for his bricks only to receive them in a badly battered condition. Don't ship bricks from New York to Yucatan!

Between New York and Vera Cruz we saw no mines; nevertheless, it will be interesting to refer to certain facts of history. The first of the islands (afterward called the West Indies) to be colonized was Hispaniola, subsequently known as Hayti and Santo Domingo. The great admiral, Columbus, had discovered it in 1492 and it was he that named it 'Little Spain.' At Isabella and Santo Domingo were founded the first settlements made by Europeans in the New World. Hispaniola was rich in gold, for the early records make frequent mention of the mines; these were the Buena Ventura placers and other diggings in the Cibao region where the forced labor of the natives was employed, often in a cruel manner, to wash the gravel. Spanish estimates of the production—according to my friend, F. Lynwood Garrison—range from \$200,000 to a million dollars per annum during the first quarter of the sixteenth century. The chief mining towns were Cotui and La Vega; as far as can be judged, the gold came chiefly from the erosion of small stringers in the diorite of the Cibao range.

It was the impoverishment of these mines that led to the colonization of Cuba. This island had been named Juana, and then Fernandina, but the Indian name has survived all the Spanish christenings. Cortez was a member of the expedition sent by Velasquez, the governor of Hispaniola, to conquer Cuba, in 1511. Subsequently, but before he invaded Mexico, he was one of those that secured an estate there, living on his plantation and introducing some of the first of the cattle that were brought to Cuba. It is interesting to note that Cortez settled at St. Jago, a name since corrupted to Santiago. He is said to have worked for gold within his domain, the deposits promising better than those of Hispaniola. But Cuba never produced much gold; it is true that the first Spaniards found the natives in possession of personal ornaments made of gold, but these represented the metal gathered in small quantity and during a long period. The extermination of the aborigines prevented their tyrants from learning anything about the source of the gold. Since that day Cuba has won a position as a mineral region, but this is due to her deposits of iron and manganese, together with those of copper, which occur within a few miles of Santiago, where Cortez was *alcade*. Across the bay, in the mountains of Cobre, are the ancient mines whence the great *conquistador* derived both his gold and copper. Their development has been revived since the Spanish-American war and it is to be hoped that they will become the basis of steady industry.

At last, three days overdue, we arrived within sight of

A Glimpse of Old Havana.

The Prado, Havana.

the Mexican mainland. It was a sunny morning, with a breeze raising white caps on the sea and moving masses of cloud from off the dark bank on the western horizon that marked the land of the Aztecs. Clouds obscured the view, mountains loomed to the northward, and among them the gleam of snow; straight ahead the sun shone on the white buildings of Vera Cruz, making a brilliant fringe along the shore. But there was no sight of Orizaba, the volcanic mountain, 17,356 ft. high, that rises from the flats behind Vera Cruz and forms a great landmark in this part of Mexico. Borrowing a telescope, I could distinguish, over the dancing blue waves, the yellow strand of St. Juan de Ulua and behind it the towers, graceful as campaniles, of the town of Vera Cruz. The white wings of fishing boats came into the picture, and northward forest-clad mountains rose massively, some of their summits crested with snow. But there was no peak of Orizaba. Almost by accident, I shifted the telescope to a higher angle and then, suddenly, in startling beauty, above the clouds, almost in mid-sky, there stood the vision of a glorious pyramidal mountain, the sun shining on the snowfields and defining the ravines, a vivid picture, strangely silent, rising above darkly wooded slopes that in their turn rose from white cumuli, below which level lines of heavy cloud served to accentuate the loftiness of the peak and also to divide the vision piercing the upper sky from the panorama of sea and shore. It was a delicious moment; no one on the ship had caught sight of the mountain; the unexpectedness of the apparition and the vividness of it intensified the deep delight produced by one of the most glorious pictures that ever awakened an artist or inspired a poet. It seemed so high above all meaner things, rising sheer from the sea, the intervening flat layers of mist accentuating the height, while the brilliant sunlight upon the snowfields made it appear closer than the lowlands at the base. In a way, it reminded me of my first view of the Southern Alps of New Zealand, as seen one morning on board ship coming from Tasmania, when the serrated peaks flanked by pine forests rose above the troublous dark green waves that came in the wake of a storm. But in that picture there was a series of high crests; here, there was one in solitary grandeur and without a peer. Scenes such as these compensate for the discomforts of travel and afford a stock of impressions from which one can draw on dark days and in restful hours when the memory harks back to the past, as to the refrain of some sweet song.

THE USE OF MATHEMATICS IN ENGINEERING.—To all but a very small group of men, mathematical formulæ remain, not only a foreign, but a repellant language, to be used for giving perfect precision and definition to ideas expressed in the vernacular. Again, these formulæ may be employed in extremity, and where verbal expression fails, much as when, in despair, we turn to Latin and Greek to drive a thought home deeper and surer than we can in English, where that latter language is either defective, or where we are clumsy in its use. And finally, we utilize them much on the same principle that we turn to medicine, when diet and the observance of the rules of health fail. Experienced teachers recognize the fact, that to the minds of nearly all men, ideas are brought more easily by means of their own native and every-day language, and by pictures or by diagrams; and, that if they are to teach successfully, they must teach, not only with all their energy, but with all their skill along the line of least resistance to the introduction of new thought; in order that, with the time and strength allotted them, they may work the greatest aid to their fellows. —HENRY M. HOWE.

The Down-Town District of Leadville.

The Down-town district includes the streets and buildings of the city. Its surface is covered by 200 to 500 ft. of glacial material, forming a gently sloping tableland which extends to the Arkansas valley, and must be passed through by mine shafts before they can reach the underlying rock in place. Very large bodies of ore, mainly in oxidized form, have been and are still being discovered in the underlying rocks, and it is to aid in their development that a special map is being prepared.

In the early surveys of the district, made in 1880-81, Mr. S. F. Emmons distinguished two divisions in the gravelly material that covers the rock in place; the lower, which is stratified and consists mainly of fine-grained sands and marls, was called 'lake beds,' while the upper division, which consists entirely of unstratified boulders and clay, was called 'wash.' The former beds were assumed to have been deposited in a glacial lake ponded back in the upper Arkansas valley by the glaciers which issued from the lake fork of the Sawatch mountains, near Twin Lakes, during the first glacial period. In the terms of modern physiography, these deposits would be for the most part more properly classed as glacial-fluvial beds, as has been claimed for the whole by glacialists who have recently been studying the Twin Lakes region; but Mr. Emmons still inclines to the belief that a lake covered a part, at least, of the upper Arkansas valley in which the finer materials, issuing from beneath the earlier glaciers, were deposited. The faulting of these beds, shown in the recent mine workings, proves a certain amount of uplift in the region back of Leadville since the glacial period.

In the original survey it was shown that the slopes of the Mosquito range, back of Leadville, consist of fault-blocks successively uplifted toward the east along north and south striking faults, in which the sedimentary beds lie in shallow synclines, the faults themselves following the steeper limb of the anticline. Recent underground developments have shown that, while the main fault-planes were correctly located, their displacement was often distributed on several planes, so that the beds to the west of each fault zone descended not with the even slope of a syncline, but in a series of steps. Depths below the surface of the basins, as determined on the syncline theory, were in general correctly given in the successive cross-sections of the original map. In the case of the block represented by the Down-town area, however, no shafts had penetrated the covering of glacial deposits, and, while a shallow syncline in the underlying limestones was assumed to exist in this block as in the others, no facts were available from which the western limit of the synclinal basin could be determined. The finding of ore in this area was primarily dependent upon whether the ore-bearing limestones had been eroded off before the so-called lake beds were deposited; in other words, whether the slope of the rock-surface beneath these beds is greater than the dip of the limestones.

Mine workings opened in this area during the last ten or fifteen years have disclosed a number of more or less parallel faults by whose displacement the beds have been carried down as though by steeper dips than those observed, thus increasing the horizontal area of possible ore-bodies. The vertical range of the beds has also been shown to be much greater than was originally supposed, the ore making at several different horizons, called 'contacts,' by the miners. While the possible extent of ore-bodies still existing in this western basin is thus shown to be much larger than was originally supposed, no sufficient data from shafts or borings are yet available to accurately determine its western limit.

Ely, Nevada.

Written for the MINING AND SCIENTIFIC PRESS
By ARTHUR H. HALLORAN.

Ely, or rather the Robinson mining district, occupies the course of a transverse gash in the Egan range in the east-central part of White Pine county, Nevada. This range is one of a large number of north-south folds rising from the desert floor of this, the Basin Region, the characteristics of which have been so well described in the writings of the earlier members of the Geological Survey. It lies 30 miles west of the Utah-Nevada line and is parallel to it for nearly 150 miles. Ely is 85 miles east of Eureka and 139 miles south of Cobre on the Southern Pacific railroad and it is this comparative inaccessibility that has prevented rapid growth. But now the Nevada Central had laid 50 miles of the standard-gauge track from Cobre (135 miles west of Ogden) and is expected to reach Ely by the end of July. This railroad follows the easy grade of the west ridge of the Steptoe valley, forming an entrance much more convenient than the present tortuous travel over five mountain ranges and across four desert valleys.

Leaving the main line of the Southern Pacific at Palisade in April of this year, I rode 80 miles south to Eureka on the Eureka and Palisade narrow gauge, taking five hours to make the trip. One should buy a ticket from Palisade to Ely for \$15 rather than pay \$8, the railroad fare from Palisade to Eureka, and the \$10 stage-fare from there to Ely. This stage runs six times a week, at this time of the year, usually requiring 24 hours of continuous riding night and day to make the trip. There has been such a congestion of traffic that travelers often have to wait their turn for two or three days at Eureka. This route in its course across the grain of the country, rises to an elevation of nearly 8,000 ft. Ely and Eureka are both at an altitude of 6,350 feet.

The Ely of to-day is yet in the making, the rawest of Nevada mining camps, just awakened to its enormous possibilities after a lethargy of thirty years. Already one thousand men are crowded into its insufficient accommodations and thousands more are but waiting convenient access and more definite data before making a rush. The past winter and spring have been the severest in years, and in consequence the roads have been bad and the hauling of supplies has often been delayed until the town was on the verge of famine. There is now abundant food, such as it is, but very little accommodation. A few fortunate ones have beds in frame houses. Many are glad of the privilege of paying 50 cents per night for a cot in a tent, and often the saloon tables and chairs are utilized as makeshift couches. All timber for building and for mining has to be brought from a distance, as nothing but mountain mahogany, juniper, and scrub-pine grow in even the most favored parts of this desolate region. An unfortunate combination of muddy roads, poor and insufficient horses and great demand caused a mighty gathering of supplies at Eureka that taxed the freighting facilities to their utmost. One team took three weeks to make the round trip. Many men have waited over a month for such baggage as exceeded the limit of 30 pounds.

The object of this 'rush' is the enormous bodies of low-grade copper ore. It is yet too early to predict their extent, but enough work has been done to show that Ely is destined to be the center of a great copper-producing region. Extravagant reports of the immensity of the deposits have been issued, based upon certain unproved assumptions. These reports have often overreached themselves in endeavoring to attract an influx of capital. There is little to suggest that these

low-grade ores can ever seriously threaten Butte's supremacy as a copper district.

While this district has been visited by many of the best known mining engineers, their reports have been made to private companies and but little has been published concerning the orebodies and their occurrence. That of J. Parke Channing, made in August, 1905, was the conservative basis for a development which has since opened up enormous bodies of copper. The ore is found in a porphyry dike, intrusive in limestone and shale. The dike has been tracked for seven miles in an east and west course. As shown by surface crop-pings, its width will vary from 1,500 to 4,000 ft. with an average of 2,500 ft. On the surface it is weathered brown, with but little trace of copper, but after sinking from 50 to 100 ft., pyrite and chalcocite are found in small seams and disseminated masses throughout the whole rock.

This igneous rock, or porphyry, has been determined as rhyolite, intrusive in Carboniferous limestone. It carries disseminated irregular grains of metallic sulphides, the latter apparently taking the place of the black bi-silicates. The mineralized areas seem more silicious than the unaltered rock. As before stated, a leached cap covers the workable ore. At a depth of from 300 to 400 ft. the ore becomes leaner, until it is too low-grade for profitable working. This suggests that subsequent to the primary mineralization of this dike its upper portions were leached and the copper re-precipitated by reaction with pyrite as first shown by the experiments made by H. V. Winchell on the Butte ore. This theory is borne out by the finding of pyrite coated with chalcocite and covellite.

This limits the depth of the ore to 350 ft. at the most, with an average less than this. It has been stated that ore has been found wherever a shaft was sunk in the porphyry, and on such foundation it has been reasoned that the whole body is mineral-bearing. That such reasoning is fallacious is shown by the occurrence of barren zones of monzonite and by the intersection of unexpected limestone bodies in depth. In a number of places the ore has been opened up for a length of 900 ft. and a width of 500 ft. Exploratory work in the two properties of the Nevada Consolidated Copper Co. is said to disclose 22,000,000 tons of ore. Channing estimated it at 12,000,000 tons, but a great amount of work has been done since then. This great mass of ore averages 2.5% copper, 40 cents in gold and a trace of silver. It is easily broken, as most of it will crumble in the hand, and it can be readily concentrated in the ratio of 9 to 1 by simple crushing, jigs and tables.

The whole lode, together with the limestone on either side, has been staked out by prospectors. Many of these claims have been gathered together to form the large acreage owned by the companies now operating. On this cropping there seems to be no claim which has not been consolidated or is in process of consolidation with others. The accompanying map (Fig. 1) shows the approximate holdings and positions of the various companies together with a rough outline of the surface geology. I could not determine whether the area marked rhyolite and tuff was wholly extrusive.

The western limits of the porphyry are being worked by the Veteran Ely Copper Co., which has opened up a large tonnage by means of a long cross-cut tunnel. George Gunn is manager and D. Shovlin, superintendent. Adjoining on the east, the Giroux Consolidated Copper Co. has done considerable work, particularly on the contact of the limestone and monzonite. Six shafts have been sunk to a depth of from 200 to 800 ft. and good ore opened in both the porphyry and limestone. A site for the concentrator has been graded and a blast-furnace

Showing Boundaries of Mining Properties.

Fig. 2. Longitudinal Section of the Ely District.

Showing Principal Shafts.

installed. The property was first worked to develop the high-grade contact deposits, but it promises also to produce large quantities of low-grade ore. The mine workings are centered around Kimberley, eight miles west of Ely.

The next holdings to the east are those of the Nevada Consolidated Copper Co., at present the best developed property in the district. It includes the combined claims of the old New York and Nevada Copper Co. and of the White Pine Copper Co. The Chairman mill-site near Ely has also been absorbed. At Copper Flat this company has two shafts, the Eureka No. 1 and Eureka No. 2, each down over 400 ft. From these, drifts and cross-cuts have opened up large bodies of low-grade copper ore which are to be stripped and extracted with steam-shovels. The ore is friable and readily handled by this method. A mile and a half to the east, the Ruth shaft has been sunk to a depth of 650 ft. on an incline of 41%. Drifts have been run at the 200, 300 and 500-ft. levels, showing an ore-body 900 ft. long and 300 ft. wide with three faces still in ore. Cross-cuts driven every 200 ft. prove the continuity. This immense body of ore is to be worked by the caving system through a new four-compartment vertical shaft now being sunk at the Star Pointer. A 60-ft. steel head-frame and an electric hoist will replace the present equipment.

An experimental mill on the Ruth indicated that a saving of 78% could be made in a water concentration of this ore. Ground is now being broken for a 1,000-ton concentrator two miles below Ely to treat the combined output of these two mines. Plans have been made for a 2,500-ton copper smelter below the concentrator and an initial unit of three 85-ft. reverberatory furnaces, with the necessary converters, are to be put in at once. An abundant water-supply has been provided.

To the south of the Nevada Consolidated and Giroux, the Butte & Ely Copper Co. has sunk a shaft 700 ft. through the leached cap into the sulphide zone. Fine specimens of chalcocite and covellite, precipitated on pyrite, are found in this mine. H. S. Wales is superintendent. Between the Copper Flat and Ruth holdings of the Nevada Consolidated, the Ely Central Copper Co. have ground that is to be tested with drills. The porphyry here is covered with what is apparently a rhyolite capping, the thickness of which must be ascertained before much development work can be done. On the east the Ruth group is bordered by the Cumberland-Ely and by the Witch group. The former is being opened up by shaft and tunnel, and the latter by a tunnel. A number of ungrouped claims to the east are soon to be united into a company.

At the present incomplete stage of development work it is impossible to more than outline the holdings and indicate the possibilities. Undoubtedly a large number of 'wild cats' will be organized to work copper near Ely, but there is every reason to believe that the companies mentioned mean business. It is possible, but not probable, that the whole of the great dike is mineralized; an assumption that it is all metalliferous has formed the ground-plan upon which has been erected an alluring superstructure promising to tower far above the substantial edifice of assured production. The real object of this has been to boom lots in the town-site of Ely. Its success is shown by the fact that a corner 49 by 100 ft. was recently sold for \$15,000. Real-estate speculators are naturally anxious that people should crowd into the district. Conservatively, it is estimated that by the end of this year 3,000 people can be profitably employed in the mines, smelters and dependent industries. But a low-grade camp is no place for a poor man. Abundant capital is necessary to open up and equip the mines. Wage-earners, except those employed in smelter construction, should

not go there until after the railroad is completed. It remains to add that 'porphyry copper' is not the only asset of this recently forgotten district. Rich lead, silver, and occasional gold veins are found throughout the tributary country. Cheap transport will solve the problem of their treatment, and it is to their development that the late-comer is now turning his attention. Companies will also be formed to prospect for contact copper deposits and possible lenses in the adjacent limestone.

PRODUCTION OF RARE EARTHS.—A number of minerals that were formerly supposed to be of extremely rare occurrence have lately been found in quantity. The discovery of these deposits is an example of the truth that the supply responds to the demand. It is the advance made during the last five years in the manufacture of various forms of apparatus for lighting purposes that has developed a use for metals and metallic oxides such as tantalum, cadmium, zirconia, thoria, yttria, and cerium, lanthanum, and didymium oxides. With the exception of cadmium, all these materials are now used commercially in the manufacture of different lamps, and are obtained from the following minerals: Monazite, zircon, gadolinite, columbite and tantalite. Monazite is the mineral which contains the oxides used in the manufacture of mantles for the Welsbach and other incandescent gaslights. Although monazite has been found sparingly at many localities throughout the United States, the Carolinas are still the only States that are producing this mineral commercially. An interesting mineral, thorianite, was discovered early in 1905 near Balangoda, Ceylon, associated with corundum, zircon, tin, topaz, spinel, etc. According to the reports on this mineral, it is one that could be more easily utilized as a source of thoria than monazite, and as it has a much higher percentage of this compound, it would be much more valuable. It is not improbable that this new mineral may be found in certain localities of the United States where tin, topaz, zircon and monazite are found. The tantalum minerals are in demand because they contain the metal tantalum. This is employed at the present time in the manufacture of very fine wire for use in the construction of a special lamp. An interesting occurrence of a tantalum mineral has recently been discovered in a feldspar quarry at Henrytown, in Maryland. Near Glastonbury, Connecticut, an old feldspar quarry is being investigated as to the quantity of columbite or other tantalum mineral that may be found in this feldspar. A mineral from Tinton, South Dakota, gives on analysis 44% of tantallic oxide and 30.5% niobic oxide. The production of monazite, zircon and columbite during 1905 amounted to 1,352,418 lb., valued at \$163,908, as compared with 745,999 lb., valued at \$85,038 in 1904, an increase of 606,419 lb. in quantity and of \$78,870 in value. From one-sixth to one-fourth of the monazite mined in 1905 was exported to Germany. — *U. S. Geological Survey.*

CONCERNING the relative efficiency of the better-class station-pumps underground we have the following data: To raise 500 gal. against a head of 3,000 ft. a compound-condensing pump will consume 1,370 lb. per hour, a triple-expansion condensing pump 1,060 lb. per hour, while a high duty Worthington pump will consume 840 lb. per hour. Compared with the first-named pump, therefore, the triple-expansion pump makes a saving of 22.63% and the Worthington high-duty pump a saving of 38.68%. Taking these various points into consideration the engineer will arrive at the conclusion that for the majority of Western mines the compound-condensing pump is all that is required, while, for shaft-sinking and general prospecting, the ordinary high-pressure pump is the most advantageous.

Business and Engineering.

Written for the MINING AND SCIENTIFIC PRESS
By EDGAR RICKARD.

In these days, when the necessity of a good technical training is sufficiently impressed upon the young men who intend to become mining engineers, it may be well to direct attention to the importance of some knowledge of business methods. At the very outset of his career, in his letter of application for a position at the mine or smelter, our young man will be fortunate if he can display some business sense as well as scientific knowledge. The chief who engages him is apt to be impressed as much by one as the other.

The management of a large company is always appreciative of business capability in every department. Great care should be exercised in making out requisitions and in preparing reports, keeping account of supplies, and in systematizing all records, so that a knowledge of existing conditions may be promptly obtained at any time. It is of great importance to see that no shortage occurs at a critical time, or that unnecessarily great quantities of any kind of supplies are carried in stock, particularly those that are perishable or which deteriorate. It is most irritating to the busy mine-manager to have the assayer report a shortage of litharge when it takes twenty days for an order to be filled from the nearest point of supply. It is equally aggravating to find suddenly that a large quantity of ammonia is useless from having been kept in stock too long. All of these irregularities and embarrassments are easily avoided by the application of the simple rules adopted in any business, and it means advancement to the man who can relieve the boss from worry, and a sure setback to anyone who causes needless annoyance. Business men with no other qualifications to recommend them, should not be chosen for mine managers in preference to technical men with some business knowledge and experience; and yet a large proportion of the managers of our largest mining properties have at most only an elementary knowledge of the technical details of the operations under their charge. The typical business mine manager is getting the big salary, and the purely technical men under him are solving his technical problems. Would it not be better to have a technical man at the head of affairs with sufficient knowledge of matters and methods to attend to the larger problems, and to leave to a purely business man on his staff those details of management which prevent him from giving personal attention to the greater problems? The technical man, because of his knowledge, his personality, his high ideals and attainments, should be the leader, and not subservient to the business man, whose judgment of many important matters is likely to be at fault. The length of time and the amount of application necessary to master the ordinary problems of business are as nothing in comparison with the necessarily long period of studious application devoted to the training of the capable technical man. I do not mean that it is absolutely necessary to have a detailed knowledge of every item of the business department, but sufficient to know that he is not being either deceived or imposed upon. A knowledge of the ordinary discounts allowed for cash payments by firms furnishing the mine supplies, and the time usually allowed for such payment; the secure investment of reserve funds; the current prices of supplies—this is information the manager ought to have at his fingers' ends.

A purely technical manager might find out too late that the terms of his contract with a smelter were entirely unsatisfactory even though he had given particular attention to the penalties charged for the presence of arsenic, zinc, or any other deleterious substance in the ore; because he had overlooked valuable by-products for which he receives nothing. An instance may be men-

tioned where large shipments of pyrite were made to a smelter in the Black Hills. Several months later the mine owner discovered that his ore contained an appreciable amount of copper. On requesting some sort of settlement on account of copper, which was not mentioned in the contract, the miner was informed by the smelter people that they bought his ore for iron and sulphur and had no record of any copper content. On the other hand, the manager who is purely a business man without technical training, and with only limited practical experience in the affairs of mines and reduction works, may be deceived, and failing to recognize the true import to the smelter of the presence of objectionable minerals in his ore, insists upon a contract which the ore buyer or smelter superintendent in justice to himself cannot sign. The inexperienced manager has allowed his strict ideas of business to carry him into deep water, and he has not only made himself objectionable and a disagreeable customer, but has exposed his ignorance, which is worse, for the fact will cripple his ability to direct the company's affairs.

The buying of supplies should be intrusted to a man whose knowledge and experience fit him for this important trust. He must also be known to be above the blandishments of sellers and the possible temptations of his position. It is necessary that the buyer of mine supplies be a competent judge of the quality and usefulness of his purchases, but this is not always the case. I call to mind an instance where the manager of a large newly organized concern bought scores of great picks—the kind known as railroad picks—with huge handles and heavy unwieldy eyes. He bought them at a discount and considered them a bargain, but the miners refused to use them, for which the superintendent, being a practical man, did not censure them in the least.

The purely business man is more often at the helm, not because commercial knowledge alone is the more valuable, but because a thorough business training includes a knowledge of men and their adaptability to certain work, and his business instinct and training have taught him how to employ this knowledge to the best advantage.

PIPES UNDERGROUND.—In many mines it is a great inconvenience, not to say a source of danger, to run long steam-pipes to operate underground hoists or pumps. Such pipes should be well covered to lessen condensation, and to prevent heat in the shaft, which is not only a discomfort, but tends to rot the timbers. Where the use of steam is undesirable, electricity, or preferably compressed air, can be used, the latter being not only safe, but aiding in ventilation and cooling. A compressor plant is needed in any mine to operate air-drills; to increase its size in order to supply, in addition, the air needed to run the underground machinery, will increase the cost comparatively little, and, at the same time, compressed air, in conjunction with proper re-heaters, is a most economical method of power-transmission. The most convenient method of re-heating is by means of steam. A small well-covered steam-pipe may be led to distances as great as 10,000 ft. to the re-heater, which must be, of course, close to the engine. These re-heaters are also made so as to be directly heated by coal, which would naturally exclude them from mines where, as in some coal mines, an open fire would be dangerous. A direct-heated re-heater 42 in. diam. by 54 in. high will heat per minute 340 cu. ft. of free air to 360 degrees F., increasing its efficiency by 35%, the air being under 40 lb. pressure per square inch.

In every mill or mine, the management ought to be able to give a reason for doing anything in a particular way.

Principles Underlying the Amalgamation of Gold in the Stamp-Mill.

Amalgamation is a physical—not a chemical—process, the catching of gold by mercury being almost instantaneous. While this is true with respect to a given particle of gold, yet, with respect to the whole mass of the ore, it is a continuous process.

With the exception of its tellurides, gold occurs as metallic or free gold alloyed with more or less silver, and, frequently, with other metals. The ores of gold are divided into two classes, free milling and refractory. The former may be defined as one in which the gold is in such form that it is readily and completely recovered by crushing and amalgamation, while, in refractory ores, this is not the case.

The purpose of wet-stamping or crushing is to free the gold from its adherent gangue, the pulp, as it passes through the battery-screens, consisting of particles of gangue and particles of free gold, which, mingled with, say, eight times their weight of water, flow over the mercury-coated apron-plates in a film or layer. The metal alone is capable of being wetted by the mercury, the ore particles of low specific gravity not being at all affected. The gold, as soon as it comes in contact with the amalgamated surface, is immediately wetted by it, just as an ordinary substance is wetted by water. The action is assisted by the fact that gold and silver, owing to their greater specific gravity, soon come in contact with, and are wetted and caught by, the mercury of the amalgamated surface. If the particle of gold is less in diameter than the thickness of the mercury film it produces no disturbing effect upon it; if greater, it forms a projecting point upon it as in accompanying sketch.

A liquid, such as this mercury film, has a tendency, due to surface-tension, to provide itself with a horizontal upper bounding surface. In the attempt to do this, in that part of the surface which has been raised up because of the gold grain lying beneath, the pull of the surface-tension, resolved into its components, tends to press down the grain upon the plate with considerable force. This force begins the instant the grain of gold is wetted by the mercury, continuing to operate as the grain is drawn beneath the surface, and constituting the so called 'attraction' of the mercury for the gold. Because of this force, grains of gold adhere to each other and to the plate with great tenacity, especially where the pulp drops upon it.

Gold-amalgam, when freshly made, may be of the consistency of soft paste, yet, after standing a few days, it will become hard and rigid, and so it is with the amalgam forming upon the apron-plate. Any condition which tends to make the gold particles less readily wetted by the mercury has a detrimental effect upon amalgamation. If the gold particle has not been completely separated by crushing, the tendency of the mercury to hold the gold particle may be overcome by the sweep of the flowing pulp-layer upon the adherent particle of gangue. Gold telluride, or gold alloyed with bismuth, becomes incapable of being wetted by mercury and so is not caught. Again, in ores which have been subject to alteration the grain of gold may be coated with oxides, sulphides or base metals so as to be incapable of being wetted. In one case the gold grains were coated with a film of calcareous silica. Very fine gold may be carried along so rap-

idly by the film of pulp upon the plate that it does not come in contact with the mercury. To prevent this the apron-plate is given a steeper grade, and as little water is used as is consistent with securing a free movement of the pulp. Such fine particles may have an adherent water or air-film so that they do not come in contact with the mercury, and so are not wetted by it.

Mercury is fed to the mortar in order that, during the violent agitation of crushing, the gold particles may be brought in contact with the mercury and thoroughly wetted. This tendency is increased by the subdivision of the mercury into fine particles; this is termed 'flouring.' By such contact the gold particle is increased in size by the adhering mercury, and is also wetted by it, so that the mercury film of the apron-plate catches a wet particle more readily than a dry one. Disadvantages are, however, introduced by this practice; they are the losses brought about by the 'flouring' and 'sickening' of the mercury. Flouring is mechanical, the mercury by the violent agitation being broken up into small drops, the surface tension of which is enormous, compared with their weight. This keeps the particles truly spherical, so that they come in contact with the amalgamated surface at a point rather than by a line. The tendency of two globules to coalesce, or to sink down to or below the amalgamated surface is slight, so that the drops are swept away and lost. Again, certain minerals will form an extremely fine slime which coats the globules, so prevent coalescence. If a floor, coated with fine dust, have some drops of water sprinkled upon it, a similar phenomenon appears, each particle being coated with dust, taking a spherical form and exhibiting a lively movement when stirred.

Soluble salts in the ore react with mercury, causing it to be lost in solution and precipitating other elements in it, tending to make it 'sick.' This sickness is of two kinds; another metal may become alloyed with the mercury making it less active, or more viscous and brittle, so that flouring may readily be induced. The fine slime also adheres more readily to the surfaces of sick mercury, and the metals in it frequently re-oxidize, forming a coating which prohibits the coalescence required.

The finer the gold the more rapidly does the mercury take it up, so that more mercury is needed to amalgamate fine gold than coarse.

The chief difficulty in the use of plain copper plates is due to the fact that a small amount of copper from the plate goes into solution in the mercury, and this is easily attacked by oxidizing agents, and by soluble salts of the ore, forming a tarnished film of copper-salts on the surface of the mercury, and preventing the gold from being caught. The difficulty is overcome by silver-plating the copper. Silver is less soluble in mercury than copper, and is less affected by the soluble salts above mentioned, and not at all by oxygen. The effect of silver-plating on the absorption of mercury by the copper plate is to restrain it at first, since the mercury has to diffuse the silver; eventually, however, the amount absorbed is approximately the same.

From a physical standpoint the temperature of amalgamation does not matter as long as it remains constant. A disturbance of plate-equilibrium arising from changing temperature is detrimental, since, in such a case, the thickness of the mercury film, as well as the absorption of mercury by any other metal, changes; and the millman then has to deal with varying conditions. Where chemical action is negligible, it might be advisable to conduct amalgamation at higher (but constant) temperatures, since the wetting of the gold particles by mercury is slightly facilitated with a rise of temperature; but a comparatively low one is better where the influence of soluble salts in the ore has to be considered.

Reverberatory Practice on Lake Superior.

Reverberatory smelting at the copper mines of Lake Superior, as compared with that for the recovery of copper from its sulphide ores, is simple. The people engaged in it have thought that they had a hard problem to solve and have been, in the past, afraid to try anything much different. The mineral, which they had to treat, already contained the copper in metallic form, and its recovery consisted in melting down a self-fluxing material, refining and casting it.

Fifteen or twenty years ago, as Egleston's monograph on the subject tells us, the charge of a reverberatory furnace was 15,000 to 20,000 lb. of copper 'mineral,' concentrated from ore (or 'rock,' as it is there called). Conventional practice today prescribes a furnace that will hold 40,000 lb. of mineral carrying upward of 70% copper. In furnaces of this size not only was the high-grade mineral melted and refined, but even that which was low-grade, containing only 30% copper. Today we find certain furnaces reserved for melting the low-grade mineral, the copper being then tapped out and sent to another furnace for refining. The high-grade mineral is, however, still melted and refined in the same furnace. For the plain melting the furnace has been made larger and capable of holding 70,000 to 80,000 pounds.

With the completion of the Michigan smelting works, near Houghton, Michigan, a different practice has been introduced, resulting in large increase of output per furnace. Referring more particularly to the refining furnaces, which take not only the high-grade 'mineral' and the nearly pure native copper, but also copper from the melting furnace, we find, according to a statement of their early work about a year ago, that they were turning out a maximum charge of 184,000 lb. In the interval they have inclosed the ash-pit of this furnace, 5 by 6 ft. in size, and have introduced an under-grate blast by which they have been able to burn 40 lb. coal per square foot per hour. This has enabled them to reduce the draft over the hearth to 0.25 in. of water against the 0.50 in. formerly used, thus diminishing the quantity of cooling air otherwise drawn to the hearth. Because of the increased quantity of coal consumed it has been possible to melt charges of 230,000 to 240,000 lb. up to a maximum of 298,000 lb. The old plea, that in undertaking to cast such large quantities, the copper would get out of pitch, seems not to have been borne out. Of course this large amount could not have been moulded by the ordinary way of dipping, using either hand-ladles or the larger ones called 'bull' ladles suspended from an overhead trolley. The casting has been accomplished by means of a Walker machine, and a single operator has been able to handle the large charge above mentioned in six hours. Indeed, it requires no great stretch of imagination to predict that in the future 500,000 lb. copper will be refined and cast at one time.

Reverberatory slag has so high a tenor in copper (10 to 25%) that it is always re-smelted in a blast-furnace which will give a slag going 0.75 to 1.00% copper. Reverberatory slags, as low as 7% in copper, have been produced under favoring conditions, and an average of 10% is usual in the best practice. Attempts are being made to make a cleaner slag by the use of reducing agents and by care in proportioning the charge so as to give a typical slag; the results are promising. It may be prophesied that some day it will be possible to produce slags so clean that they will not need blast-furnace treatment and may be thrown away, thus dispensing with the after treatment altogether. This result will again be assisted by the use of the long furnaces of the Anaconda type, recently described in the columns of the MINING AND SCIENTIFIC PRESS.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

Nickel is found generally with basic magnesian rocks—norite, serpentine, and rocks containing much olivine. It is usually accompanied by cobalt minerals.

The ore from West Point, Cal., marked Blue Mt., is Mispickel (arsenical iron-sulphide). It may be gold-bearing. This can be ascertained by assaying.

The minerals from T. C., Spokane, are: No. 1, principally Chrysocolla, with Tenorite; No. 2, amount too small to determine, but scales look like molybdenite, rather than tellurium; No. 3, Epidote.

Mid-summer is not a suitable time for those unaccustomed to the desert to attempt to prospect in that region. Now is the time to get into the high Sierra from southern California to British Columbia, leaving Death Valley and other equally hot localities for the winter days.

The rocks from Medical Springs, Ore, are: No. 1, Chert; No. 2, Semi-opal; No. 3, Aplite; No. 4, also Aplite, but stained with iron oxide; No. 5, Grano-diorite with much infiltrated quartz; it also contains iron oxide, and may be gold-bearing; No. 6, another phase of the Aplite.

The rock specimen from Los Angeles, marked F. G., is much altered, but consists chiefly of original hornblende, chlorite and feldspar, mostly much kaolinized, but probably orthoclase. There is little original quartz in the rock. This would determine the rock to be Syenite. There are numerous veinlets of quartz in the rock of secondary character, having no connection with the original rock.

The rocks from Tonopah, Nev., marked J. O. A. S., are: (No. 1 and 2, missing;) No. 3 A, apparently an igneous rock much altered and now consisting principally of calcium carbonate and silica; No. 4 A, Obsidian in which occur numerous feldspar crystals; No. 5 A, Diorite-porphyrity; No. 6 A, a silicified eruptive rock, original character now undeterminable, because of alteration; No. 7 A, a silicified and iron-impregnated rock, probably originally Aplite.

THE following table shows the development of transatlantic steamships in certain directions since the Cunard company entered the field 66 years ago:

	Britannia. 1840.	Umbrin. 1884.	Campania. 1893.	Lusitania. 1906.
Coal for trip (tons)	570	1,300	2,000	5,000
Cargo (tons)	224	1,000	1,620	1,500
Passengers	115	1,225	1,700	2,350
Horsepower	710	14,500	30,000	68,000
Coal per horsepower (tons)	5.1	1.3	1.6	1.4
Speed (knots)	8.5	19	22	25

It will be seen from the above table that since the first Cunarder was built 66 years ago, in order to increase the speed threefold the power has been increased 100-fold, and the coal consumption for a voyage ninefold. The coal per horsepower has been reduced, owing to greater economy in use, and the reduction of the length of the voyage from fifteen days to four and a half, which latter is the time estimated for the new boats. It will be noted that, although the Lusitania will carry more passengers, she will carry less freight than the Campania, on account of the room required for coal and machinery due to her higher speed.

Mining and Metallurgical Patents.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

CONCENTRATOR FOR PULVERULENT MATERIALS. No. 821,819. Richard G. Newman, Wandsbek, near Hamburg, Germany.

In a concentrator, the combination with an air-blast, of a serpentine conduit having vertical sides, connected at one end to the delivery end of the air-blast and a pipe connection between the other end of the conduit and the suction end of the air-blast, thereby forming a closed circuit, a dust-collector connected with the said pipe and closed receptacles connected to the conduit to receive the separated material.

APPARATUS FOR THE TREATMENT OF ORES AND TAILING. No. 822,398. August Soderling, Bodie, California.

Apparatus for preliminary treatment of tailings and slimes, consisting of an inclined riffled trough or conductor having at its upper end a water-supply, and pulverizing-rolls, and a tank holding a weak solution of solvent acids or acid salts, a dilution water-conductor near the lower end of said trough, and at its lower end settling-reservoirs for sands and for slimes, final reservoirs for base-metal solutions and separate terminal reservoirs for the sands and for the slimes.

MORTAR FOR STAMP-MILLS. No. 822,914. Martin P. Boss, San Francisco, California.

In a stamp-mill mortar, a mortar-body having an opening in its top provided with an inwardly inclined wall, in combination with a housing composed of separate similar halves, each half comprising a semi-cylinder to receive the stamp-head and a base with a flat inclined outer face to fit the inclined side wall of the top opening of the mortar-body, whereby the two halves are wedged together in seating.

ROASTING-FURNACE. No. 823,393. Arthur W. Chase, New York, New York.

In a roasting-furnace the combination of end walls provided with openings, bridge-walls, a series of substantially U-shaped troughs supported within said end walls, conveyors in said troughs, means for driving said conveyors, a plate provided with circular openings adapted to fit around the openings in the end walls, said plate being provided with slots and removable plates each made in two sections fitting around the conveyor-shafts and adapted to close the openings in the end walls, said plates being adjustably secured to the first-named plate.

ROCK-DRILL. No. 822,596. Arthur H. Gibson, Easton, Pennsylvania.

A tool-piston having a front rod and a tail-rod, a cylinder having a tail-rod chamber, pipes for feeding motive fluid alternately to the opposite sides of the piston and a single means for bringing the tail-rod chamber into open communication with the pipe which effects the forward stroke of the tool or to the atmosphere at pleasure.

ROCK-DRILL. No. 823,059. E. Letcher, Nevada City, California.

In a rock-drill, the combination as set forth, of a shell, means for turning and advancing said shell, a cylinder within the shell, a fluid-actuated piston reciprocating within the cylinder, an exteriorly shouldered chuck-body separably disposed within the forward end of the shell and abutting against the forward end of the cylinder, a bushing secured in the forward end of the shell, a cushion-ring disposed between the bushing and the shoulder of the chuck-body, and keys engaging the bushing and chuck-body and adapted to permit reciprocation and prevent rotation of the chuck-body and bushing relative to each other.

Special Correspondence.

LONDON, June 20.

There has been some enquiry for Dolores shares during the last few days on news from the mine concerning No. 1 cross-cut at the third (bottom) level put through the lode at a point where in January last some high assays were obtained in drifting on the lode. At this point the ore is proved to be 35 ft. wide for an average assay-value of \$101. The welcome announcement is also made that at last the cyanide plant is at work, and giving an extraction of 95% of the precious metals. The profit at the mine for the month of April is given as \$18,598 from 692 tons crushed; that is before the cyanide plant started running.

The Esperanza dividend of 5s. 6d. has had little effect on the shares, the mining market generally being in the doldrums.

A circular has been issued by the Camp Bird directors explaining the quite unavoidable delay in informing the shareholders of the cost of repairing the damage done by the snowslide and fire. The total will be about £70,000. At the time of the accident cash in bank and on short loan amounted to about £120,000. From the insurance companies £6,600 has been collected, and further small payments are expected. A larger sum was not recovered owing to the fact that the insurance did not cover loss caused by the snowslide, but was confined entirely to that portion of the mill subsequently destroyed by fire. It has been decided to re-build, on the site of the old mill, a 60-stamp mill, making provision in the building for a further 20 stamps, and to erect snow barriers. It is expected that crushing will be resumed early in December. On receipt of the report and accounts, the directors hope to meet the wishes of a large body of the shareholders by resuming the payment, at least, of small dividends during the time occupied in re-building the mill.

A notable example of "linked sweetness long drawn out" is to be found in the Linares Lead Mining Co., Ltd. It was first registered as an English company in 1852, and is now undergoing reconstruction on modern lines with shares of £1 each, instead of £3. On its modest capital of £45,000 the Company has paid considerably over a million sterling in dividends.

Another reconstruction now in hand, but of a very different category, is that of the Um Rus Gold Mines of Egypt, Ltd. After being in operation for about 3½ years without attaining a dividend-paying position, the Company is short of working capital. The mine is said to be opening up in a most promising way. The ore reserves are put at 10,000 tons of fair milling grade. The results of this Company, one of the best which came on the scene with the advent of the new regime in Egypt, are not such as to inspire confidence in the future of that country as an important gold-mining centre.

A report covering 18 months' operation has been issued by the Akrokerri (Ashanti) Mines, Ltd. It states that gold to the value of £90,560 has been won during the 11½ months since the mill started, as a result of crushing 18,270 tons. The actual running time was 244 days, the greater part of the time lost being due to lack of fuel, and fire in the native village. The directors were able to obtain a reduction of the prohibitive rate of 51s. 3d. per ton for the carriage of coal fuel from Sekondi, to 15s. 1d. A reserve stock of coal has now been accumulated at the mine. The railway rates on machinery, stores, etc., are still exorbitant, and the directors are continuing to make representations, although, so far, with little success. The net profit is £8,872, after writing off £14,425 for depreciation and a further £23,751 for mine-development redemption, equivalent to 26s. per ton on the 18,270 tons of ore milled. This figure of 26s. per ton has been arrived at by dividing the total cost standing to the debit of mine development at December 31 last by the tonnage of ore in sight in the mine at that date, added to the tonnage extracted and milled during the year. Since that date, however, development has proceeded much more rapidly and economically. The total tonnage in sight and estimated in the mine at April 30 was over 50,000 tons. The cost of development at the present time has been reduced to 14s. 6d. per ton, and it is fully expected that this figure will, as time goes on, be continually reduced until it reaches a normal level of,

say, 7s. 6d. per ton. The net profit shown is also subject to a royalty of five per cent to the Gold Coast Government, as well as to assessment for income-tax in this country. Two winzes have been sunk to a depth of 95 ft. below the third level, and the fourth level is now being driven at this depth, and will be completed much more rapidly than the upper levels, as the work is being done by means of air-drills. The directors are adding to the existing plant an additional powerful air-compressor. The opening up of the northern workings has also received special attention, in view of their bearing on the question of increasing the capacity of the mill. The general power-plant is designed for working 40 stamps, although only 20 stamps have, so far, been erected. The intention has been to install these additional 20 stamps and correspondingly to increase the capacity of the cyanide plant as soon as the development of ore reserves, both at the southern and northern workings, justified the doubling of the extraction. It is estimated that the total cost of installing this additional plant will not exceed £8,500. During the five months from January 1 last 9,810 tons of ore have been crushed, yielding £47,087. Providing this same rate of production is continued to the end of the year, the value of gold recovered would be about £20,000 greater than during 1905, and should the extra 20 stamps be ready for work in December or January next, it is confidently believed that a profit of £10,000 per month, after deducting all charges, including mine development, will thenceforward be made.

For a development and exploration company having a capital of nearly £300,000 (including debentures) the profit for the year 1905, £24,000, of the Consolidated Gold Fields of New Zealand is not of striking importance, especially having regard to the variety and extent of the Company's mining operations. With regard to recent legislation affecting the mining industry of the country, the following paragraph in the general manager's report is noteworthy:

"It is with great regret that I have to comment on the legislation which has recently come into force under the heading of the 'Bank to Bank Clause.' This clause will have a very serious effect on the Golden Fleece mine, for under the old conditions employees used to walk in and out of the mine in their own time, the distance being approximately 1½ miles each way. The shifts then relieved one another at the shaft, but under the 'bank to bank' conditions a man's time commences from the time he enters the mine. This has the effect in this mine of reducing the net working time the company is entitled to, from 7½ hours to 6½ hours, a very serious loss, which will have to be deducted from a very slender profit."

The first annual report of the reconstructed Great Boulder Main Reef, Ltd., from the date of the Company's incorporation, Feb. 25, 1905, to Feb. 28, 1906, states that Mr. Albert Wauchope was appointed general manager in place of Mr. W. W. Barton, taking charge on March 1 last. Since the general clean-up in the early part of 1905, the treatment plant has not been worked, exploratory and development work only having been carried out. At the time the Company took over the property the main shaft was down to a depth of 1,400 ft.; since then it has been sunk to the 16th level (1,550 ft.), and thence to the 16th level (1,700 ft.). From the development of these levels, the manager considers the prospects distinctly encouraging, and if the orebodies as disclosed by the drifts and cross-cuts fulfil expectations, the working capital in hand should prove sufficient to both reconstruct the plant, and to place the mine upon a payable basis. The manager reports that in the upper levels there still remains a quantity of payable ore which, when the plant has been brought up to date, can be treated at a profit.

The conversion of two of the leading Cornish tin mines from the 'cost book' to 'limited liability' was formally confirmed by shareholders' meetings last week. Grenville United Mines, Ltd., will have a capital of £60,000 in shares of £1 each, 10 shares for 1 of the old company, and South Crofty, Ltd., a capital of £20,000 in shares of £1 each, in lieu of the 6,120 old shares.

It is stated that The Sudan Exploration, Ltd., is going into Cornish tin. The board is said to have under consideration a number of tin propositions in Cornwall, and announces that it has now secured leases and agreements for leases upon eight sets, containing about 1,200 acres, which form an im-

portant tin mining area. It is hoped that tin in Cornwall will prove a more payable proposition than so far has been the case with gold in the Sudan. It would appear that the boom in tin has awakened considerable interest in other minerals known to exist in the county, notably that of pitch-blende, antimony, zinc-blende and copper. A pitch-blende property near St. Ives is said to have been taken up by a group with a view of working the mine for copper and tin in addition to that of pitch-blende, of which a good vein is now laid open at the adit-level. This property was worked some 60 years ago under the name of Trenwith. An antimony proposition is being worked by a group of local people near Padstow. The prospects here are considered to be of a highly encouraging character, as a good quantity of the mineral has been raised. And at Bolingey, near Perranporth, operations on a fairly extensive scale are being vigorously pushed on, with a view of finding copper beneath a very rich course of blende. The Company is now sinking the shaft with a powerful pumping plant and other necessary requirements are being provided for fully proving the property.

JOHANNESBURG, June 4.

This city has had its full share of discreditable mining fiascos since the war. First there was the Coronation Syndicate, which a few years ago was going to do wonders in the Heidelberg district. Today they have given up Heidelberg, and are trying 'to strike oil.' Then came the Madagascargascar bubble, when the samples of the reporting engineer were salted so successfully that he issued one of the rosiest reports ever made. This proved a complete swindle. A few months ago we went through the Geduld affair, when the first samples from that mine were salted, sending up the shares. Just recently we have seen the collapse of the Louis Moore, a small mine in the northern Transvaal, reported to have bright prospects. Lastly, but worst of all, comes the terrible disappointment of 'Sallies.'

One of the chief assets of South African Lands (Sallies) was supposed to be the tin mine at Vlaklaagte. About a year ago Sallies was the favorite horse on the Stock Exchange. The rise of the stock was sensational. The £1 shares mounted to £8 10s.; but today you can buy them for 6s. 9d. It was declared by a few and believed by many, that Sallies tin mine would prove the greatest of its kind in the world. Today it is not far from a collapse. All kinds of reports were made on Sallies by all kinds of men, from the highly poetical, imaginative romancer, to the level-headed, cautious mining engineer, desirous of getting at the truth. Perhaps the gem of this collection is this extract from a report of W. Bettel: "Owing to the nature of the lode or 'stock-work,' the expenses, mining and metallurgical, incidental to the extraction and refining of the metallic tin will be very small, and it may be found that the output will require control to prevent undue depression of the tin market. I believe that the enormous extent and value of this stanniferous deposit is barely exceeded in importance by the deposit of gold in the Witwatersrand formation." For optimistic gush this takes a lot of beating! Great things were promised shareholders as soon as the mill commenced operations. The results show a very serious discrepancy from what was promised. The total amount of material won so far is about 25½ long tons of cassiterite, equal to 17.85 tons or 1.75% metallic tin from 1,020 tons treated. The directors appointed two engineers to make a report on the discrepancy. "Gross carelessness" is the strongest term used in the report. What the public want to know is why many men 'in the know' commenced off-loading their shares months ago, while stoutly maintaining that Sallies would prove the greatest tin mine known.

The Sallies collapse will be a heavy blow to the legitimate mining of base metals in the Transvaal. People hoped that Sallies would be the beginning of a great base metal industry in this country, but the failure of this tin mine will depress the enthusiasts. One of the curses of mining in the Transvaal is the close relationship between the Stock Exchange and the mine. Some unprincipled men look upon mining solely as a legitimate form of gambling. A small prospect is found; an 'expert' whose favorable opinion can be bought for a few shares, goes off to visit it in a motor car,

and returns the same day with the report that it is the "greatest thing on earth." The prospect is pronounced a full-fledged mine and floated. The shares are eagerly taken up, the sharks get the money, and the public gets—left. Every mining community has such disreputable episodes. The Transvaal seems to have had more than its share of late. These fiascos bring the country into disrepute, quite undeserved, and cripple legitimate prospecting and mining.

TORONTO, July 1.

On June 25 Chancellor Boyd rendered judgment in the action brought by the Government of Ontario against Edward C. Hargreaves and the White Silver Mining Co., to set aside leases of Cobalt mining lands, on the ground that they had been obtained upon false declarations of valuable mineral discovery. The case excited great interest on account of the fact that it is likely to form a precedent in the disposal of many similar cases, and owing to the large number of witnesses examined, the trial lasting for ten days. The decision turned principally upon the evidence of George Haines, the prospector, who swore to the discovery, but the judge considered it too contradictory to support the claim and accordingly gave judgment for the Government, holding that they might cancel the lease, but must indemnify the holders for actual expenditures incurred. The property affected by this decision comprises 120 acres of valuable mineral land near Kerr lake and about two miles southeast of Cobalt town. An appeal has been taken from the judgment, which is having a very disquieting effect, as there are a large number of claims, which have been disposed of by the original holders into the hands of individuals or companies actively engaged in development of equally doubtful validity.

Considerable dissatisfaction with the provisions of the new Mining Act prevails in the Cobalt camp, and a number of petitions are being prepared and mass meetings called in Cobalt, Haileybury and New Liskeard to bring pressure to bear upon the Government. Some wild talk is even indulged in, of the secession of New Ontario from the Province, and the establishment of a new provincial organization; but this is not taken seriously. The principal objections taken are to the inspectorship system, which, it is claimed, gives the inspector too much arbitrary power. There is no absolute standard of the value which a claim must show in order to satisfy the inspector, and it is asserted that many claims have been rejected, which have afterward turned out to be rich. The strongest protest is made against the system under which there are two or three applications accepted for the same claim. It is often the case that after a prospector has spent time and money on a claim and, becoming satisfied with the indications, is prepared to go on with development, the inspector refuses to pass it. Others then come on and continue the work and in the end secure the title. The miners ask for stability of title at every stage, and denounce the practice of permitting several applications to be under consideration simultaneously as an encouragement to claim-jumping.

Discoveries continue to be made in the region north of the Cobalt area. In the Wendigo Lake district, some 25 miles north of Cobalt, three young prospectors have made a good find assaying 23% silver. An eight-inch vein of cobalt, showing silver and nickel in paying quantities, has been found on the Blanche river, eight miles below Tomstown. A good vein of molybdenite has been discovered in the Temagami forest reserve.—The Nova Scotia mines in the Cobalt area have struck a 12-in. vein carrying 50% silver at a depth of 70 ft. Other veins on this property show increased richness as lower levels are reached.

Shipping and trenching work is being actively pushed on most of the old mining properties of the Cobalt camp, and good finds are matters of almost daily occurrence. On the Columbus-Cobalt property three important veins have been found in addition to the six-foot lode of cobalt that is being worked. This is the only mine in the district yielding cobaltite, and the ore carries a high percentage of silver combined in an unusual manner with cobalt. A 100-ft. shaft is being sunk and 100 ft. of driving is going forward, the work being pushed day and night.—Numerous accidents from blasting, drilling, etc., are occurring, which are largely due

to the ignorance or inexperience of many of the men employed, who are new to mining.

SALT LAKE, July 1.

The ore and bullion settlements reported for June by Salt Lake banks aggregated \$2,056,300. The month was an unprecedentedly active one in the camps and both the United States Smelting, Refining, & Mining Co. and the Utah Consolidated Co. reported the largest single month's bullion output in their history. The Utah Consolidated produced about 2,000,000 lb. copper.

Samuel Newhouse has closed a deal whereby he comes into possession of something over 100,000 shares of stock in the Silver King Consolidated Mining Co. at Park City. This property is situated near the Silver King mine, of which former U. S. Senator Thomas Kearns is manager. At a meeting of directors last week, Mr. Newhouse was made vice president of the Silver King, and Lafayette Hanchett, manager of the mines, was made a director. Samuel Newhouse has also secured an option on the Commoner and other properties at Silver City, Idaho, and M. M. Johnson, his chief field representative, has returned from making an examination of them. The property tied up is situated on War Eagle mountain.

The Honerine Mining Co., operating at Stockton, Utah, has succeeded in inducing the managers of the American Smelting & Refining Co. to make certain modifications in their contract. Some time ago the Honerine management contracted to deliver the output of the mine for a period of five years, but the conditions of the instrument turned out to be not altogether favorable to the mining company; now that the changes have been made, it is expected that production upon an elaborate scale will be undertaken.—The New Stockton mine has its shaft down to 1,000 ft. and is running for the orebodies on that level. The mill is treating 60 tons of ore daily, working two shifts, which is all that can be done with the plant because of water shortage. The company is likely to build an aerial tramway to the valley below and there provide new facilities for concentration and power. The New Stockton mine contains some extensive bodies of mill-ore. J. J. Trenan of Salt Lake is manager.

The ore shipments from the Tintie mining district last week aggregated 130 carloads, the shippers and amounts being: Ajax, 3; Beck Tunnel, 5; Black Jack, 7; Bullion Beck, 8; Carisa, 8; Centennial Eureka, 33; Dragon Iron, 8; Eagle & Blue Bell, 3; Eureka Hill, 14; Gemini, 5; Grand Central, 6; Godiva (concentrate), 2; Mammoth, 4; May Day, 1; Ridge & Valley, 3; Scranton, 4; South Swansea, 1; Swansea, 3; Yankee Con., 4.—The Bullion Beck & Champion Mining Co., after a lapse of eight years, has appeared among the list of dividend payers again, the directors having distributed \$10,000 this month, making a total of \$2,700,000 paid out by this company during its existence.—Recent developments on the lower levels of the Mammoth mine have been of an important character. At 2,269 ft., the bottom of the mine, assays taken across a full breast gave returns of 11% copper, 22 oz. silver, and \$20 in gold.

Papers have been filed effecting the legal consolidation of the Goodsell and Imperial properties in American Fork canyon. The new company is known as the Mountain Dell Consolidated Mining Co., and the officers are: President, J. H. Wotten, American Fork; vice president, W. L. Goodsell of Salt Lake; treasurer, A. W. Raybould of Salt Lake. The management of the Utah Copper Co. has decided to provide a more extensive power equipment for its Garfield mill than the original plans called for. It is the intention now to install a plant of 10,500-h.p., which will not only supply the mill with electric energy, but also the company's mines at Bingham. The cost will be about \$750,000.—The campaign for the removal of the overburden from the copper-bearing porphyry ores of the Boston Consolidated at Bingham is progressing favorably. A Keystone driller is in operation and, with it, holes are being sunk to depths of from 20 to 35 ft. About 40 holes are to be drilled, when a carload of black powder will be used to fill them. The ensuing explosion will shatter the surface so as to facilitate the work of the steam-shovels.—About eight feet of good shipping ore has been opened in the vein recently encountered on the 200-ft. level of the Montezuma mine.—

The mill of the Ohio Copper Co. is now equipped with a battery of 20 concentrating tables, four of the Johnston type having just been added. The company is preparing to equip its mine so as to work to greater depth and get out larger tonnage.—At a special meeting of shareholders of the Utah Apex Mining Co., also operating in the Bingham district, the action of the directors in authorizing a \$500,000 bond issue, was ratified. Only \$100,000 worth of these bonds will be issued at present, the proceeds to be used in building an aerial tramway, a new compressor plant and for development purposes. A long adit is being driven to tap the veins at depths of from 800 to 1,000 ft. The tramway will be used from the mouth of the Andy tunnel, one of the upper workings, until the adit is finished and connections made with the developed portions of the mine.

The equipment of the New Red Wing mines, operated by the Utah Development Co., which was contemplated for this summer, has been delayed at least until autumn. It is intended to erect a plant to treat 500 tons per day. In the mine some extensive bodies of low-grade ore have been found.

The ore shipments from Park City to Salt Lake smelters last week aggregated 4,667,460 lb., the shippers and amounts being: Daly-Judge, 1,078,000; Daly-Judge (zinc middling), 575,000; Daly-West, 1,140,000; Kearns-Keith, 219,000; Silver King, 1,148,460; Little Bell, 458,000; Jupiter, 49,000.—The Jupiter mine is to be equipped with a small mill, the management having purchased a second-hand plant.

At Alta much development work is being done and production is steadily on the increase. The Columbus Consolidated is the principal shipper at the present time. A new producer is the Silver King, which is marketing about 20 tons of ore per day. The Con. Flagstaff will soon have its new compressor plant ready for operation, but the management is continuing the adit into the mountain in the meantime by hand. Seven fissures have been encountered, the last one being cut last week at a distance of 1,290 ft. from the portal.—The Albion Co. continues to carry on its campaign of development with encouraging results, and is preparing to build a mill, if not this year, then in the spring of 1907. William Hatfield, of Provo, is the manager.

It is announced at Pioche, Nevada, that a consolidation of the Bristol and Hillside companies' possessions has been effected, the new company to be known as the Bristol Consolidated Mines & Smelters Corporation. Strong Eastern people are behind the Enterprise, and the combined properties are to undergo extensive development preparatory to providing facilities for ore treatment. The Bristol company has been shipping ore regularly to the plants of the American Smelting & Refining Co. at Salt Lake.

DENVER, July 2.

Another regrettable lawsuit has been started at Cripple Creek. Judge W. S. Morris, of Colorado Springs, as attorney for the Jennie Sample Mining Co., has brought suit against the estate of James J. Cone, owner of the Ophir mine, for \$200,000, alleging that this amount of ore was extracted from a vein apexing on the Minnehaha claim of the Jennie Sample Mining Co. It is evidently the same old apex question again. Cripple Creek is a perfect complex of veins. As a man who has had considerable experience in apex suits once remarked to me: "I can apex any vein in Cripple Creek anywhere it is wanted." There is a lot of truth in this remark. Within 100 ft. of the surface one can mine in almost any direction, following some sort of a vein or crevice all the way, simply by selecting the veins or crevices that go in the direction that one wants to go. Of course the experienced mining men of the camp draw a very sharp distinction between the series of veins that have been found to be ore bearing and the countless other seams which are barren. Unfortunately all veins look alike to the average jury and the decision of an apex suit is just as apt to go to the impostor as to the rightful owner. Many of the Cripple Creek mines have had the good sense to eliminate trouble by agreeing among themselves that the boundaries of their claims shall define their property to indefinite depths. Nor is this custom confined to Cripple Creek. The same rule has been adopted to good effect in the Morenci district of Arizona. Such action speaks louder even than the resolutions of the American Mining Congress, that the American

miner is thoroughly disgusted with the apex law and wants some more simple rule by which he may acquire government mining property.

A mining district of promise has been discovered on the Uintah reservation, in Utah, not far from the Colorado line. The formation consists of upturned limestone beds seamed with dikes of trachyte and other eruptive rocks. The mountains are quite high and the underlying granites and quartzites have been thrust to the surface near the top of the range. While but little prospecting has as yet been done in the high hills, some extremely rich ore has been found, and it is thought that the granite and quartzite area will be found to contain profitable lodes.

The famous old Caribou district is to be re-opened by a long adit from Cardinal, if the plans of Col. S. B. Dick, of Meadville, Pa., are carried out, and as Col. Dick has fulfilled his purpose heretofore, it is quite probable that this enterprise will go through. If it does, it will mean a great deal for western Boulder county. The Caribou mine is credited with a production of \$6,000,000 in silver. It was finally closed down in 1896 on the advice of T. A. Rickard. Since then the price of silver has gone up and the price of mining and ore reduction has gone down, and while I do not know that there is any great amount of low-grade ore actually blocked out, it is more than probable that there is more than one big orebody in the district. The lowering of the water-level will facilitate the prospecting of the ground.

There is a district west of Granite, Colorado, which promises to become a producer. J. Loggin, of the Twin Lakes placer, showed me a lot of the ore and gave me information concerning the district which convinces me that there is merit to it. The following, from the *Mining Reporter*, tells part of the story concisely: "Not since the first mineral discoveries at Leadville has the outlook for the Twin Lakes district been so bright as it is today. Electric and steam plants are to be installed, and at least two mills will be installed and operated this summer. One is being erected by Judge Harrison, Fred Robinson and others, of Leadville, at the base of Champion mountain, in Lackawanna gulch. This gulch is near the very summit of the Continental divide, and, notwithstanding the rich ore found on the mountain sides, it has been kept back owing to the high altitude and difficulties of transportation. Better weather conditions have inaugurated an era of activity in this part of our district. Several four-horse teams loaded with a crusher and other machinery went there last week, the old Bromley mill has also been purchased and will be moved soon; also another mill was transported last fall, and the whole combined will soon furnish an up-to-date reduction plant. A romantic history is connected with this claim. More than a score of years ago, when Lackawanna had an incipient boom, a Missourian by the name of Roberts located the Miller vein and opened an extremely rich body of free gold ore. Owing to unforeseen circumstances he had to leave suddenly and return home; but, before his departure, he drew a rough sketch of the mountain and of the valuable deposit. He never returned, but several years later his nephew, having received the map, came to Twin Lakes to recover the property, to find that during the interval the Robinson brothers had relocated the abandoned claim, resulting in a lawsuit that finally ended with a compromise. The present owners have opened a four-foot vein, from which several rich shipments have been made. Adjoining the Miller lode lies the old Dick Turpin claim, from which in the past several thousand tons of float have been shipped. The writer, when inspecting this property, found on the surface many specimens of quartz showing free gold. This claim is owned by Tingley S. Wood, a prominent mining man of Leadville, and forms a part of his Theodolite group, extending into Half Moon gulch, it being one of the best mining propositions in Lake county."

There are now two dredges working in the Iron Springs placer field, near Steamboat Springs. The new Blivens dredge is reported to be successful.

The snow is leaving the high ranges very slowly. Last year I started teaming to a property I am working at an altitude of 11,140 ft. on June 20; this year, it will be after July 4 before the first team can get through. Notwithstanding the late season, there is an unusual amount of prospect-

ing being done this summer, and I have information of important discoveries from all over the State. Not a few of these stories are coming from the country traversed by the Moffat railroad, which, in a general way, means northwest Colorado. The information in most cases is not sufficiently confirmed to warrant publication, but there can be no doubt of the conclusion these stories indicate when taken in the aggregate, namely, that this year is to be one of many new and important discoveries.

BISBEE, July 2.

The consolidation of four of the Bonanza Circle companies is still commanding the most attention in this district. The new company has not, as yet, got matters thoroughly in shape. Among the companies consolidated, the Lake Superior & Pittsburg has made the best showing. In both of its main shafts large bodies of ore have been encountered. On the 1,100 level in shaft No. 3, a large orebody, consisting mostly of carbonates and oxides, was opened up; this ore averaged 16% copper. The Jessie, Iron Cap, South Bisbee and Glencairn claims have also been proved to be rich. The second company of the consolidation is the Pittsburg & Duluth. Its shaft has been sunk 1,400 ft., and the main levels are at 1,200 and 1,350 ft. The principal orebody is on the 1,350 level, where a large body of sulphides has been opened up. Pittsburg & Duluth has been shipping 125 tons per day to the Calumet & Arizona smelter at Douglas. The third company is the Calumet & Pittsburg. The Calumet & Pittsburg had much trouble with water and it took a long time to get pumps that were able to handle the flow, but since that has been accomplished things have been progressing in a most encouraging way. On this property are two shafts, namely, the Briggs and the Hoatson. Drifts have been driven at various levels in each, and ore has been encountered in nearly all of them. The remaining company of the consolidation is the Junction, which has one shaft that has been sunk 1,200 ft. On the 1,000-ft. level the development is in a large body of oxidized ore. All of these companies have installed modern machinery and equipment. With this showing the Superior & Pittsburg Co. starts on its career.

The Copper Queen Co. will install a central electric plant to supply its mines at Bisbee and its smelter at Douglas. The improvements at the smelter are well under way. The smelter is still turning out copper at the rate of 8,000,000 lb. per month. There is some talk of the Phelps-Dodge Co. erecting a concentrating plant at their Nacozari mines, but nothing is settled as yet.—The Calumet & Arizona smelter is turning out 1,200,000 lb. copper per week.—At the Shattuck property, on Friday, the drift on the 700 level broke into a body of black sulphide ore, which assays 25% copper. Stopping will commence at once. This body of ore, and those opened up on the 300 and 500-ft. levels, make the Shattuck one of the richest in the district.—At the Denn-Arizona the drifts on the 1,000-ft. level are still in porphyry. The drift to the southeast of the diamond-drill bore has passed through the conglomerate and is now in limestone. The flow of water increased a little this week, but not enough to cause inconvenience. There are new pumps ready that it is thought will take care of all the water that is likely to be encountered.

Sinking and driving are still going on at the Cochise with no new important developments.—The Chiricahua Development Co., in Paradise district, has shut down and it looks very much as if this property would revert to Captain Burns, the owner, in September, when the last payment is due. It is a good district, and it is to be hoped that should this occur, operations will be resumed under a new management.—The Elwell Gold Mining Co. has commenced operations in the Huachuca mountains. Machinery, supplies, and men are on the ground. George R. Welborn, president of the company, is supervising the arrangements.

—The American & Development Co. in Sonora, Mexico, passed into the hands of a receiver this week, as a result of the long-continued squabble among the stockholders.—Developments at Tombstone are encouraging. The water is gradually being controlled, and 450 men are working steadily. The ore shipments are being increased appreciably, and the cost of treatment steadily decreased.

CANANEA, Mexico, June 30.

A body of silver-lead ore has been encountered in the main shaft of the mine of the Cuban Consolidated Copper Co., which is situated near Arizpe, about 40 miles south of Cananea and 85 miles from the Arizona border. This is on the 135-ft. level; cross-cutting has been started to determine the extent of the orebody. The ore is being sacked and will be shipped in carload lots as soon as ready. The property of the company consists of about 500 acres.—Ore averaging 8% copper and carrying about 25 oz. silver has been found on the 100-ft. level of shaft No. 2 of the Cananea-Duluth Copper Co.'s property. A drift was started last week to determine the extent of the orebody and the 35 ft. of drift is all in the same ore. From surface indications it is expected that this orebody will develop a width of over 300 ft. Work has been discontinued on shaft No. 1 until the hoisting machinery arrives, and it is expected that it will be ready for sinking within two weeks. An offer of \$250,000 is said to have been refused for this property last week. It is considered one of the richest of the Cananea camp and is on the south end of the Cananea ore-zone.

Shaft No. 4 was started ten days ago on the property of the Oro Maximo Mining Co. at Basaitequi, 40 miles south-east of Cananea. The shaft was sunk on one of the richest croppings on the property and has more than come up to expectations. It is now down about 35 ft. and is in ore running \$650 per ton. Cross-cuts will be started on the 100-ft. level and are expected to show the lode to be over 15 ft. wide. The two other shafts, which are down over 300 ft., are in ore giving assays of from \$150 to \$1,000 per ton. This is the largest gold property being worked in the district, employing about 250 men and using the latest mining methods such as air-drills, etc. The final load of timbers for the 200-ton mill left Cananea this week for the property.—Native copper has been found in the prospect shaft on the Bonanza lode of the American Mining Co.'s property, which is situated in the Cananea ore-zone at about one mile from Cananea. In the Bonanza shaft the body of ore which was reached two weeks ago and which runs as high as 48% copper, with an average of 35%, continues to increase, and it is the intention of the management to ship 1,500 tons of this monthly as soon as it is opened up. Five tons of this ore are being shipped daily to the El Paso smelter.

Regular shipments of from 150 to 200 tons per day are being made from the Copper Queen Co.'s Sierra de Cobre mine to the Douglas smelter. This mine is situated in the midst of the mines of the Cananea Consolidated Copper Co. and is one of the richest mines in the district. The ore runs about 5% copper. The development work has been going on for two years and at present there are 100,000 tons of this 5% ore in sight.—The Axurite shaft of the Fortuna Mining Co. has encountered copper-silver ore averaging \$550 per ton and the cross-cut, which is 9 ft. long, has shown the orebody to be large. The full extent of it has not been determined, but there are over 200 tons in sight. One hundred tons will be shipped as soon as possible. The property is situated near Arizpe, about 45 miles from Cananea.

In the drift on the 100-ft. level of the Ortega Mining Co.'s property, ore running 6% copper and carrying 18 oz. silver has been found and the drift for 45 ft. is in this ore. The ore is being sacked for shipment and will be sent to the smelters as soon as the management can make arrangements. The property is situated in the Manzanal mountains, about six miles from Cananea.

BUTTE, July 3.

The East Butte Mining Co. will have its entire new surface plant completed and ready for use within the next four weeks. The new hoisting engine is in place and the head-frame is being erected over No. 1 shaft, which is down 425 ft., and a cross-cut is being run north and south from the 400-ft. level. It has reached a point nearly 100 ft. south and 50 ft. north. Double that distance will have to be gone before any of the known veins are reached. The cross-cut will be driven through the entire width of the company's ground and will intersect 20 veins. At the extreme southern end another shaft is being sunk and is nearly 200 ft. deep. It will connect with the long southern cross-cut, and the ground to that depth will be opened for mining. The

company's tributaries, working in six shafts, are hoisting 200 tons of ore per day, yielding an average of 7% copper. The company is paid a royalty of 25%, and the June income from that source was \$15,000.—The North Butte Co. has purchased from James A. Murray the Adirondack mine, a small fraction lying between the Speculator and Edith May, paying \$150,000 therefor.

The Red Metal Company has resumed work on the Nipper mine, and has contracted with the Parrot Company to hoist through the shaft of the latter company.—The Reins Copper Company has run its cross-cut from the 1,200-ft. station of the Combination mine to the northern limit of the claim without encountering a lode. A small vein had been cut at the 800-ft. level, but it evidently pinched or is faulted. The company will probably make an opening farther to the east and cross-cut again in the hope of striking a vein.—The Pittsburgh & Montana Copper Co. is shipping between 100 and 125 tons per day to the Washoe smelter. The company is not making money at present, but since it quit operating its own smelter it is not losing any.

The Butte-Milwaukee Mining Co. has begun work on the Pollock, one of its group of claims northeast of the city. A hoisting engine with a capacity to work to a depth of 1,500 ft. is being installed, and as soon as the machinery is in place, the shaft (which is 350 ft. deep) will be unwatered. A tunnel connects with the shaft at a depth of 100 ft. and the water will be pumped into this adit. The company owns the Pollock mine, and is in position to take up the bond on the Florence. It also controls the Colonel Sellers, Bird and several other claims. There are three veins on the Pollock; one of them is close to the shaft and is the only one on which work has been done.—Butte and Michigan men have organized the Ida-Montana Development Co. The company has under lease and bond two claims known as the Ida and A & B, situated a short distance south of the mines being developed by the Lewisohn General Development Co., southeast of the city. The Ida has been opened by a shaft which is 100 ft. deep, at which depth some fairly good copper and silver ore was struck. The options on the properties provide that \$175,000 shall be paid in cash for each claim and one-fifth of the stock to be issued.—The shaft of the Bullwhacker mine has reached a depth of 215 ft. It is the intention of the company to run a cross-cut at 400 feet.

Among the active new companies in this district are the Butte & Bacorn, Butte Copper Exploration, Butte & Hercules, General Development, Butte-Milwaukee, Butte Copper, Butte & Veronica, East Butte Extension, Butte Central Copper, Calumet & Butte, Butte & St. Louis, Butte & London, Butte-Montana, Reins, East Butte, Bullwhacker, Butte & Michigan, Butte & Summit Valley and the Eagle. Forty or more others have been organized during the past year but are not doing anything.—The Butte-Montana Co. has begun work on the Little Annie mine, the shaft of which has been sunk to a depth of 200 ft. The company also has an option on the Alex Scott, adjoining the Leonard mine of the Boston & Montana. The new machinery at the Butte & Summit Valley Co.'s claims has been installed and sinking will soon be resumed. The shaft on the Saratoga is down 50 ft.—The new hoist on the North Butte was put in operation last Monday. It is one of the largest engines in the district.

Thirteen companies operating in this district produced, during the twelve months ending June 1, 4,467,917 tons of ore and other companies averaged about 250 tons per day, making the total 4,599,167 tons for the year. It is estimated that the present rate of increase will bring the total for the year ending June 1, 1907, up to 5,100,000 tons. The North Butte alone expects to increase its output 146,000 tons, and the Red Metal (Butte Coalition) and Anaconda companies will increase their outputs nearly one-third. Among the new companies not yet producing, but which are expected to be shipping ore within six months, are the Butte Copper Exploration Co., Butte-Milwaukee Co., Butte Copper Mining Co., and several others. The big companies referred to last year made gross earnings amounting to \$52,328,662.

The shaft on the Butte & London Co.'s claim, the Greendale, has reached a depth of 430 ft. A station was cut at 400 ft., and a pump with a capacity of 400 gal. per min. was

installed. The company has built an engine house, has installed its new engine and the boilers are now being set. The three shafts of the Butte & Bacorn are now going down rapidly after much delay. The compressor at the Belinda mine has been installed and will furnish air for both the Belinda and Calumet, pipe connections having been made between the two shafts. The bottom of the Belinda shaft is now in country rock, the vein having pitched out of the shaft to the south.

While excavating for the foundation of a building on West Granite street, adjoining the courthouse a few days ago, the apex of a copper vein was exposed five feet below the surface. Samples assayed nearly \$100 in silver and copper per ton. The vein is 10 ft. wide, and has a north-west-southeast strike; it is on the Thomas claim, of the Davis-Daly Estate Co. The Thomas lies just south of Clark's Original mine, from which a cross-cut 3,800 ft. long will be run at a depth of 1,800 ft. for the Davis-Daly Co. by the Clark Co. The cross-cut will run through the Thomas lode.

The smelter of the Montana Ore Purchasing Co., which was acquired by the Butte Coalition Co. when it purchased the Heinze interests from the United Copper Co., will be shut down in a few days and will be dismantled. The new owners have been running the smelter since the first of February, but it has not been an economical plant. Amalgamated experts, who examined the smelter after the Butte Coalition came into possession of it, condemned it at once, and, after several months of operation, it was decided to abandon and dismantle it. Ore shipments ceased July 1, and in a few weeks the supply on hand will have been disposed of and the plant cleaned up. It has cost the new company \$3.94 per ton to treat ore at that smelter, whereas the average cost of smelting ores at the Washoe smelter is \$2.15 per ton. Hereafter all Coalition ores will be smelted at Anaconda, and it is expected that that company secured from the Washoe a rate that must be better than the cost of treating ores at the old Heinze smelter. The North Butte is paying a rate at the Washoe that last year averaged \$4.84 per ton. The capacity of the Washoe smelter is being increased. Its present capacity is 10,000 tons of ore per day.

IN brick-laying and masonry, the over-lapping of bricks or stones in one course over those below is termed 'bond.' It is done to prevent vertical joints being carried up in the work, which joints, being of mortar, are weaker than the stone or brick. In common brick walls each sixth or seventh course of brick called 'headers' is laid cross-wise of the wall, while the other bricks laid lengthways are termed 'stretchers.'

THE material used for suction and discharge pipes for pumps is almost always iron or steel. While cast-iron is used for water-works purposes, and is less subject to corrosion than iron or steel, still pipes of such material are heavy and the sections hard to handle. Wrought iron or steel costs less, gives greater security under the shock of the water (water hammer) and is easily cut and fitted to place in the mine. It is a fault of pipe manufacturers to recommend pipe of insufficient thickness. This is due to the strong competition and to the fact that mining men do not themselves calculate the strain of the water on the pipe. The bursting of a pipe-column may easily cause great damage, or even loss of life.

MANY water-power plants, otherwise well designed, have been rendered inefficient by bringing the water to the wheel in pipes too small for the quantity they had to carry. If much water has to pass through a small pipe it must necessarily flow fast. Even for large-sized pipes a higher speed than 6 ft. per sec. cannot be recommended. High speeds of flow involve a loss of working head. For example, a pipe, 1000 ft. long with 100 ft. fall, is 7 in. diam. and the quantity of water flowing through it 100 cu. ft. per min. the speed is 6 ft. per sec. Were the water standing in the pipe, the pressure at the lower end would be 43 lb. per sq. in. but when 100 cu. ft. per min. is flowing through it, the pressure drops to 33 lb. per sq. in. equal to a loss of 22%. By using a 9 in. pipe this loss is reduced to 7 per cent.

Mining Summary.

ARIZONA.

COCHISE COUNTY.

George R. Welborn, president of the Ellwell Gold Mining Co., has left Tombstone for the company's property in the Huachuca mountains, in the southwest corner of the county, to begin operations. A force of men has already arrived at the camp and has begun work. Welborn states that a shaft will be sunk 200 ft. to the vein. Machinery and supplies have arrived at Hereford and are being transported to the mine. It is the intention of the management to equip the mill and mines with electric power and to do away with the use of gasoline for lighting and power.—George Bernard, foreman of the Gold Mountain property, has men timbering 400 ft. of the 600-ft. adit recently run in the property. Bernard states that work will be resumed and continued until the ground is thoroughly tested. He reports the indications good.

GRAHAM COUNTY.

It is generally reported from Clifton and Morenci mining districts that a strike of large proportions is anticipated by the mining companies operating there. In Morenci the signs of trouble are particularly apparent, the Mexican laborers and miners of the camp having held secret meetings for some time past and conducting themselves in a sullen manner which usually foretells trouble. They have, all of them, kept their accounts closely traded up at the company's store so that when pay-day arrives there will be only small amounts to their credit. Trouble is feared only with the Mexicans, the Americans in the camp having expressed themselves as well satisfied with the treatment they are receiving at the hands of the company. Four hundred Mexican miners are in the employ of the Detroit Copper Co., at Morenci, and as many more in the mines of the Arizona Copper Co., at Clifton, and the properties at Coronado and Metcalf. Several days ago an eight-hour day was granted the miners of the section where the trouble is feared, with a reduction in wages of 25c. per day. The working day had previously been 12 hr. Since then secret meetings of the miners have been held several nights every week. The situation is similar to the one preceding the trouble in that camp three years ago when it was necessary to call out the militia. The rangers have been advised of the situation and Captain Rynning is now at Morenci with a number of his men. The sheriff of Graham county is authority for the statement that the most serious trouble was anticipated on the first of the month. It is also reported from Globe that trouble in that camp will likely result at any time, following a clash between the colored miners and the Slavonians employed there.

CALIFORNIA.

AMADOR COUNTY.

A young Italian named Chiesa was killed in the Kennedy vertical shaft one night last week, by being caught in the timbers while being hoisted with his companions to the surface. His crushed body after release from the rapidly rising skip fell nearly 3,000 ft. to the sump.—Negotiations are in progress for the sale of the Defender mine, near Volcano, one of the most successful mines of Pioneer district.

Complaint is being made of the scarcity of skilled miners in Amador county. It is claimed that 100 more miners could be given employment in the mines here, and that the men are not to be had. First-class miners get from \$3 to \$3.50 per day. There is no scarcity of common labor such as shovelers. It is hand-drillers, machine-men, timbermen and chuck-tenders that are needed. One reason assigned for this scarcity is that many men went to San Francisco, attracted by the \$4 a day offered for hod-carriers and helpers. The Central Eureka, South Eureka, Keystone, Wildman, Kennedy and others, could employ a number of good miners if they were obtainable.

The Burlington shaft, on the south side of Sutter Creek, near the Baliol property, is down 325 ft., and cross-cutting has begun at the 300-ft. level, to cut parallel veins. Frank Bernardis is superintendent.

BUTTE COUNTY.

W. Howard has struck rich ore in the adit being run on the Young America claim near French Corral, on the Yuba. Stringers containing free gold are being encountered, and every indication points to a vein a short distance ahead. The property consists of seven claims.

CALAVERAS COUNTY.

Wayne Darlington, general manager, and G. B. Easley of the Bagdad-Chase Gold Mining Co., have recently been at Copperopolis and Hodson examining mining properties in the vicinity of Hodson, in Salt Spring valley.—The Union copper mine at Copperopolis is now equipped with hoist, concentrator and smelter. Fifty tons of matte are produced daily carrying 50% copper.—Hodson near the Royal Consolidated mine is almost deserted and the property is closed down and in the hands of a receiver.—The Mountain King, an extension of the Royal Consolidated, is dropping 10 stamps.—The Alto mine, near Stanislaus river, below O'Byrne's ferry, is running. The 40-stamp mill crushed last year 75,000 tons of ore.

NEVADA COUNTY.

A strike of good ore is reported made in a winze sunk on the 300-ft. level of the Conklin mine near Grass Valley. The vein is small but rich.

Judge Nilon, in the superior court in this county, has decided, in the case of Joseph E. Osselin, *vs.* Oliver et al., that the land grant to the railroads may include mineral lands. The court denied the motion of defendants for nonsuit, which had been interposed when the plaintiff rested his case, the court ruling that the plaintiff had a prima facie case in connecting his title with the patent issued by the Government to the Central Pacific railroad. When the defendants offered to prove the character of the land in dispute by attempting to introduce evidence tending to show it to be mineral the question arose as to whether the patent could be attacked in such an action as this, or in any other manner than by a direct proceeding in the name of the Government brought for the purpose of cancelling the patent, on the ground of fraud or mistake occurring in obtaining the patent. Many cases were cited to the effect that the Land Department was the exclusive judge of the character of the land up to the time of the issuance of the patent, and that its judgment in that respect could not be reviewed or questioned in any proceeding other than one instituted for that purpose solely. The cases read to the court further stated that the stability of title is a factor in the prosperity of a community not to be overlooked, and that ample opportunity is afforded a mineral claimant for filing a protest during the pendency of patent proceedings. Following the decisions presented the court rendered judgment from the bench in favor of the plaintiff quieting his title to the entire tract of land in dispute, including the Moonlight quartz mining claim, as far as it conflicts with the Osselin ranch at Gold Flat, adjoining the Chicago mine. It is stated that the defendants will appeal.—With its mine flooded and both dumps idle the Union Hill Co. is now planning to install a complete electric pumping system which will handle all the inflow that will, in all probability, ever be encountered. It was only recently that the steam pumps broke down. They were repaired but have again gone out of business and the shaft is filling up. The company purchased the property only a short time ago. A large vein was struck recently. Until a new pumping plant can be put in, work will be practically suspended at the Morydena, a new mine being opened up at Kentucky ridge five miles northwest of Grass Valley. The shaft is down 46 ft. sinking on a vein two feet wide which carries fine-looking ore. Free gold is frequently seen. The sulphurets are rich. Little has ever been done in the Kentucky ridge district in developing quartz veins. The management is preparing to crush at a local mill.—A five-stamp mill and a rock-breaker are being put in at the Republic mine in Graniteville district, near Nevada City. Room will be made in the mill for an additional five-stamps, which will be added later. Two long adits are run. On the dump is sufficient ore to keep the mill running for several months without drawing on the mine. Heretofore the owners of the Republic have been milling their ore at a neighboring plant. This is another example of a mine which

once paid well, was closed, lay idle for many years, finally reopened and after some development again became a good producer.

The Red Cross mine, at Omega, is to be re-opened. J. A. Brent of San Francisco, who formerly operated the property, has taken a bond on it from the Western Exploration Co. The mine is equipped with a 20-stamp mill, compressor and machine-drills, besides numerous buildings. For three years the mine has lain idle; now Mr. Brent proposes to drive the adit ahead to reach a large orebody.—The Ocean Star mine at Ormonde, owned by M. D. Cooley and recently bonded to A. Maltman et al., is being opened up. Things are being put in shape to drive the adit ahead and open the mine in a systematic manner.—With both pumps out of commission and the mine flooded, the Union Hill will install an electric pumping plant to replace the present system. The mine undoubtedly gathers much water from the creek near by, and recently the pumps broke down, but it was thought they could be repaired sufficiently to enable operations to proceed, which expectation was not realized. Frank Enzensperger, superintendent, has given up hope of again doing anything with the old pumping plant, and states that the mine will be equipped with the latest in the electrical pumping line. The Union Hill has a large vein and some high-grade ore has been taken from the mine recently. The company of lessees who operated for nearly a year prior to the present company taking hold, took out high-grade milling ore almost from the start.

PLACER COUNTY.

At the Three Stars mine, seven miles northwest of Auburn, 30 men are employed, and it is reported good ore has been found.

SAN BERNARDINO COUNTY.

The people who have been prospecting the gravel of Klinefelter wash, 20 miles northwest of Needles, where placer gold has been found, have quit work and shipped their engines and pump. They found such a flow of water that they were unable to get to bedrock, although they found gold in the clay strata above bedrock. While it is believed that there is gold on bedrock in paying quantity, the efforts which have been made to demonstrate it have all failed. The development of water in the wash should be a valuable asset to the owners of the mines, as water in that region is both scarce and necessary.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The Dives-Pelican Co. is installing a Crane washer at the head of the mill to handle the material as it comes from the breaker. The ore after going through the washer goes onto a picking belt where it is sorted, and from there to the Samson crusher and thence to bins discharging to rolls, and on down through the mill over the tables. The ore makes 50% fines and it is the intention to cut out 9½ tons waste from every thirteen tons handled of the fines. It is believed this method will cheapen the cost of treatment in the mill and leave the material in better shape for jigs and Wilfleys. It is estimated that the cost of handling all of the material through the mill at present is 65c. per ton which the washer will reduce to 12c. per ton.

Silver Plume, June 27.

A strike is reported in the Piltz group in East Argentine district, which is being worked under lease and bond by Clark and Van Hoven. A vein of lead ore 12 in. wide has been encountered in the main level which gives good returns in silver and lead from \$8 to \$10 gold. The Argentine railroad is convenient to this property.—The Two American Sisters Mining, Milling, Power & Electric Co. has been organized to construct a water and electric power plant on Clear creek below Georgetown, and to operate the American Sisters mine on Silver creek. J. J. White, of Georgetown is at the head of this enterprise. The company has secured a suitable power and mill-site along the creek and the race-track will be converted into a lake for water storage.—A 500-h.p. electric power-generating plant will be erected on the Hewett ranch, and power and light lines will be extended to the mine, where a concentrating mill will be built and a large compressor installed. The property has a record of producing about \$2,000,000.

SUMMIT COUNTY.

(Special Correspondence).—The main cross-cut adit now being advanced in from French gulch through the Mono Co.'s ground to cut the Abundance vein is making rapid progress. This adit will intersect several known veins, among them the Old Union, which is being worked by the Abundance Co., and which is furnishing the bulk of the ore now being tested by its 150-ton concentrating mill. All shaft work at the Abundance property is, for the time being, suspended until the adit is driven far enough to make connections. The diamond-drill plant operated by the same company in Yuba Dam flats has already pierced several orebodies.—The Pennsylvania mine, at Argentine, is working a full force in the mine, making regular shipments of high-grade smelting silver-lead ore. The 40-ton mill is running full time on the lower grade ore, turning out a high-grade concentrate.—The Silver King mine, on Nigger hill, has been the scene of an important strike. In starting a new shaft a vein, hitherto unknown, was cut seven feet from the surface. The ore is mostly lead carbonate and iron oxide which gives by assay 0.5 oz. gold, 35 to 40% lead and several ounces silver per ton. The vein is from 16 to 20 in. wide. This is the sixth vein opened up by the lessees in this property within the last 18 months, and they have made large shipments of smelting ore which contains \$42 per ton net.—A rich body of high-grade ore has been cut in the main shaft of the London mine in Hoosier gulch. This was intersected at a depth of 200 ft. in the main vertical shaft which is being sunk to the lower limestone formation. M. M. Howe, of Breckenridge, is manager of the company.—The Summit Banner placer mine is working with full force under the management of Lemuel Kingsbury. They are washing about 4,000 yd. of ground per day which is yielding, on an average, 15 to 20c. per yd. During hydraulicking operations lately quartzite boulders carrying visible gold have been unearthed indicating that these placers are not far from the veins which produced the gold. Assays of these boulders have given returns up to \$285 per ton.—The Banner is working and this season's operations promise to be profitable.—The management of the Buffalo Placer Mining Co., at Dillon, is also in the hands of Mr. Kingsbury, who is getting the property into shape for work similar to that at the Banner. A load of rifles went up to the property yesterday.—The Atlantic Gold Mining Co., operating a property on North Star mountain, has taken a long lease on the Sovereign mill, at Montgomery, and is getting it into shape for treatment of free-gold ore. The mill is well equipped for amalgamation, concentration and cyanidation, and thorough tests will be made as to the best method of treatment for the ore. Frank Lawrence is in charge of the works.

Breckenridge, June 28.

TELLER COUNTY.

G. H. Holman, C. H. Noyes and Edgar McDaniels, operating the Comet claim of the Isabella under lease, have cut ore in the first level from the Comet main shaft, at a depth of 50 ft., and will put in machinery. They expect to be hoisting within two weeks. In the meantime the orebody will be sought from a similar depth in the incline shaft, which is 50 ft. northwest of the main workings.—J. B. Cunningham, of Victor, is shipping regularly two cars of two ounce ore from his lease on the 300-ft. level of Stratton's Independence mine.—F. S. Prettyman, manager of the Ironclad mill of the Cripple Creek Homestake Mining & Reduction Co., has been appointed manager of the large mill of the company and expects to begin operations there by the middle of July. The mill is equipped with a plant that cost \$130,000, and has a capacity of 1,000 tons of oxidized ore per day. Prettyman believes that he has discovered a body of ore that will furnish this quantity in the Homestake Co.'s Ironclad and Magna Charta claims.

J. D. Spencer of Clyde brought to Cripple Creek recently half a ton of fine-looking ore. The discovery was made by Mr. Spencer after eight years of prospecting near Clyde. Notwithstanding disappointments he continued to drive his adit, and now has a seven-foot vein. All ground in this vicinity has been staked at one time or another, although several of the claims have been abandoned. A rush to the district is now anticipated.

IDAHO.

BLAINE COUNTY.

The lowest adit in Nay Aug ground near Hailey has found the ore anticipated, the heading having recently cut into a solid foot of galena. Beside this there are several inches of concentrating ore carrying zinc. There was ore for 350 ft. in the adit-level worked last year and the strike is believed to be a continuation of it in depth.—The Dollarhide mill has been shut down for a few days to put in a settling tank and to enable the teams to catch up with the output. Although the mill is in operation only 10 hr. per day, it makes concentrate faster than teams can be secured to haul it to the railroad. There are four carloads at the mill, and as there is room for more, it necessitates re-handling. An effort is being made to get teams in order that the mill may be kept going 24 hr. per day.

SHOSHONE COUNTY.

The Great Western will soon be doing work with machine-drills. The compressor has been set up and the pipe-line from the compressor to the receiver, 560 ft. in the adit, is now being connected. The poles for the power-line are being put up and it is expected the wires will be strung and ready for use inside a week. The parallel vein, cut some time ago, continues to show galena and copper ore.—Richard Daxon, manager of the Tarbox mine near Wardner, reports the winze completed, the station on the 600-ft. level finished and the cross-cut to the vein on that level well under way, 15 ft. having been driven. It is estimated the vein will be cut 80 ft. from the shaft on this level. The showing on the 550 ft. was so good that the management is putting in a sawmill preliminary to building a 200-ton concentrator.—An option has been taken on the Cooney group situated east of the Poorman, near Burke, by John A. Ryan. The price agreed upon is \$160,000, and if the bond is executed 10% will be paid down. Mark Cooney is the largest owner, the other owners being John Kelly, Peter D. Lambert and Frank Murphy. The group consists of 12 claims, four of which have been patented.—Work has been started on the Little Butte group, which adjoins the Great Western mine on upper Canyon creek. It is owned by Mr. Rossi of Wallace and M. J. Farrell and Mack Cyr of Burke.—The Inter-State Co., operating in the Sunset country, proposes to run an adit from a point as near Nine Mile as practicable. Approximately 3,000 ft. of driving will be required to get under the best ore in the upper workings.—In two weeks more the Frisco mine at Gem will be working full blast. At that time the company will commence sinking a 200-ft. shaft from its 2,000-ft. level. On February 1 of this year the great undertaking of unwatering the mine was commenced, draining being done with two 1,000-gal. bailing-tanks. The company installed two large steam-pumps, but they cannot be worked profitably in connection with the bailing-tanks, as the steam is condensed by the water before it reaches the pumps, and the tanks accomplish more than the pumps would.—A rich strike has been made in the Colwyn mine in the Sunset peak district of the Cœur d'Alene. The mine is owned and operated by the Idora Mining Co. A stringer was discovered at the 200-ft. level and this, on being followed, widened until the entire face was in ore, which is galena assaying 50% lead and 25 to 30 oz. silver. Lead carbonate was also discovered in the foot-wall of the vein by a cross-cut. The company will build a concentrator to treat the low-grade ore.

MICHIGAN.

HOUGHTON COUNTY.

Announcement has been made of a voluntary five per cent increase in wages of all employees of Wolverine, Mohawk, Tamarack, North Kearsarge, Osceola, South Kearsarge and Ahmeek mines, becoming effective July 1. Nearly 6,000 men are benefited by this increase.

MONTANA.

SILVER BOW COUNTY.

Announcement is made by the company operating the properties controlled by the Butte Coalition Co., that the Montana Ore Purchasing Co.'s smelter will be closed down early in July and the ore from the mines now treated there will be sent to the Washoe smelter at Anaconda. The Mon-

tana Ore Purchasing Co.'s smelter, in conjunction with the Basin concentrator, operated by F. A. Heinze under lease, treats about 1,200 tons per day and employs 300 men. The ore being treated at the Montana Ore Purchasing Co.'s works is from the properties acquired from Heinze by the Butte Coalition Company.

NEVADA.

ESMERALDA COUNTY.

On the Detch-Brewer lease of the Goldfield-Daisy Mining Syndicate, Detch and Brewer have made a strike in which \$4,000 worth of ore has been taken out. Their shaft is 150 ft. deep. The new strike was made in a 220-ft. cross-cut from the 80-ft. level. The vein is four feet wide, with a 14-in. streak running through the centre in which the best ore occurs. Detch and Brewer only recently secured two more blocks of adjoining ground, giving them 400 ft. in length, in the centre of which is the shaft where the find was made. Their lease runs 18 months. This property is a mile north of Diamondfield. — On Sunday night, in the drift on the 150-ft. level, running south, on the Jumbo a seam of rich ore was found. A small pan of this ore gave nearly a teaspoonful of gold. — The Nevada-Goldfield Reduction Co. will install a Butters filter for the treatment of its slime at Goldfield. This will be similar to the plant at the Combination mill. Mark R. Lamb designed the plant. Most of the machinery for the sampler and for the completion of the mill is here or on the way, and it is expected that the mill will be in a position to buy ore within a few weeks.

LINCOLN COUNTY.

(Special Correspondence). — A short time ago attention was called to the interest being manifested in the Searchlight district by men prominent in mining affairs and by the outside public in general. This interest appears to be enduring. Contrary to the condition which usually prevails in the desert mining camp during the summer season, merchants are active and report no falling off in trade. The freight wagons are as busy hauling supplies as they were in winter. Mr. White, formerly president of the El Paso bank of Colorado Springs, and Mr. Wilson, a mining man, have bought the Le Roy mine and will install a new 25-h.p. hoist and a Cornish pump. They will straighten, enlarge, and timber the shaft. — The Searchlight Mining & Milling Co. has put in a cyanide plant of 100-ton capacity to be used in treating the dump tailing. A large pump, 60-h.p. gasoline engine, and a full electrical plant have also been ordered. This addition to its equipment will enable the company to operate on a much larger scale. Sinking in the main shaft and exploration of other known veins will begin with the installation of the new machinery. J. W. Short, a prospector, has just brought in some samples of ore taken from his claim at Lewis' hole, 12 miles southwest of here, which assay \$5,000 per ton. Short returned to the scene of his strike accompanied, and followed, by an excited crowd of prospectors from Searchlight, and a stampede of goldseekers is now heading for the new bonanza. The formation is described as being gneiss and rhyolite. — Francis Ormond has deeded his Searchlight holdings to W. W. Hurt of Los Angeles. The Ormond interests include the Ormond addition and the Daylight group of mining claims, comprising 100 acres north of town. — At El Dorado canyon the Techaticup Mining Co. will sink a new double-compartment shaft and install a hoist and other machinery. In the 670-ft. main shaft the last 50 ft. of the vein was almost flat, but it has now assumed a pitch of 75 degrees and averages \$100 per ton in gold and copper. — The El Dorado Canyon Mining & Milling Co. is driving an adit into the hillside on the Buster Brown claim which will give several hundred feet of stoping ground.

Searchlight, July 2.

NYE COUNTY.

It is reported that Donald Gillies has superseded John McKane as the representative of Charles M. Schwab in Nevada. Mr. Gillies has been associated with the Schwab properties for some time. Mr. McKane has resigned from all of the Schwab properties in Nevada in which he was in any way connected. It is said that McKane offered his holdings to Schwab, who declined them, preferring to have the market absorb them, believing that he could obtain the

stock for less in this manner than in any other way. As a result, apparently, of this move, stock in the Tonopah Extension mine at Tonopah, dropped in the Wall Street market on Thursday, the 5th inst., from \$15 to \$4.50 — a depreciation in stock value of \$10,500,000.

A press dispatch from Tonopah says: While union men are saying little about the organization at this point of the Tonopah Mine Operators' Association, the advertised purpose of which is to promote harmony and a universal wage scale between the companies and their employees, it is known that the miners are quietly strengthening their organization, anticipating a campaign of gradual resistance upon the part of the mine owners. August 1 it is intended by the mine owners to put into effect a universal wage scale in the camp. There will probably be no friction about the matter this time, but the close union of the employers, the most important of whom are now non-residents, indicates that the union will not be dealt with as leniently as before. Outside of Nevada it is not generally known that a large majority of the miners in the southern country are Colorado men, Western Federation members, who were driven out of Colorado. Their feeling against the Colorado operators is intense and they have bound up southern Nevada in the strongest unions ever formed in any State. So powerful they are that when Colorado operators who assisted in their expulsion attempted to enter southern Nevada they were promptly driven from the districts. Both political parties, for two years, have dreaded an outbreak of hostilities between operators and employees. The State has no militia, and as long as the union influence can prevent it there will be no laws friendly to militarism enacted in Nevada. On every occasion upon which there has been friction the political leaders in the State have done all in their power to establish harmony. They especially hope, upon the eve of the campaign, that there will be no trouble. — A new strike has been made in the main adit of the Gibraltar at Rhyolite. The vein is several feet in width, with a rich streak in the middle. The ore is being sacked for shipment.

NEW MEXICO.

GRANT COUNTY.

Theodore W. Carter, of Silver City, has sold his five mines, constituting the Monarch group, near White Signal, to Harry L. Martin, of Los Angeles, California. The mines are in the Burro mountains.

OREGON.

BAKER COUNTY.

The Golconda mine, near Sumpter, is again in operation, and 20 stamps are crushing its ore. In the mine three pay-shoots have been found and are being developed.

SOUTH DAKOTA.

CUSTER COUNTY.

At a recent meeting of the Black Hills Mining Men's Association, C. W. Robbins, of Custer, described the ore of Custer county as so complex as to resist treatment by any known process. The most of these refractory ores are auriferous and are combined with arsenic.

LAWRENCE COUNTY.

The new cross-cut at the Globe mine, near Lead, intended to develop veins found last winter, has reached the 200-ft. mark. According to the calculations of F. E. Ickes, manager, it will be necessary to drive 400 ft. to tap these ore-bodies. Two shifts are employed, and machine-drills are used. Samples recently taken averaged \$6.50 per ton gold. The ore is in phonolite, carrying pyrite and fluorite. — The plans of the Mogul Co. at Pluma, for the construction and equipment of its new mill, embody the latest in cyanide practice. The plant is being designed by J. V. N. Dorr, who also has supervision of construction, and will be in charge of the plant after its completion. The results of the operations of the mill at Terry which was destroyed by fire were taken into consideration and exhaustive tests made upon the ore from the different mines of the company. The ore coming from the mines in cars by the Burlington railroad will be dumped into large storage-bins at the top of the mill, and drawn from them to two No. 5 Gates crushers that will break the material to pass a 2½-in. ring. Thence it will go to

four sets of 14 by 36-in. rolls, and from these to four six-foot Chilean mills which will discharge into Dorr classifiers—a machine for the separation of sand and slime invented and perfected by the superintendent—and thence to the sand and slime departments. In the sand department the leaching will be accomplished in eight vats 25 by 10 ft. The higher grade sand will be reduced to slime in a tube-mill, and will go thence to the slime department. The slime will probably be handled by the Moore process, although this point has not been definitely decided. Precipitation by zinc-shaving will be used throughout the plant, which will have a capacity of 300 tons per day.

The Homestake slime plant at Deadwood is nearing completion. A steam road-roller has been used in the filter-press room to make a solid gravel foundation for the concrete floor that is to be laid in this department, which is 65 by 270 ft. and will contain 24 presses, having a capacity of 1,400 tons daily.

UTAH.

JUAB COUNTY.

The Little Edgar Mining Co. has filed articles of incorporation. The company is organized to do a general mining business, with Eureka as the principal office. The officers and directors are John T. O'Brien, president; C. Gustaldi, vice president; J. A. O'Brien, secretary and managing director; Jere Driscoll, treasurer; and Jesse O'Brien. The mines are in Tintic district.—It is reported that the South Eureka and other adjoining property will form the basis of a company to be incorporated for the purpose of developing this ground, which adjoins the Centennial-Eureka on the south.—Robert Brown of the Centennial-Eureka mine, Herbert Hopes and B. N. C. Stott recently inspected the Prairie Bell Co.'s property, in which they are interested. Work is still being done in the adit under the direction of Joseph Burrows.—George W. Riter, of the Eureka Hill Co., says the lessees now at work in the mine are nearly all taking out a good grade of ore.

SALT LAKE COUNTY.

There is much satisfaction in Bingham district over the announcement that the local miners' union, a branch of the Western Federation of Miners, at a recent meeting, voted down the proposition of a walk-out of all labor in the camp. It is believed that this action will meet with general approval, and that the miners will profit in the long run as a result of this course. It has been learned from Salt Lake that the mine-owners had decided to stand together as a man and not grant a single concession to the union. It is a fact that they had made preparations to shut down all properties rather than yield to the demands of the miners. The latter are aware of this and contemplate another trial by voting on the proposed strike once more, the next time on August 3.

SEVIER COUNTY.

During the past week a strike of a big body of lead ore a few miles south of Monroe has been reported. In driving an adit to develop a water supply for the Edward Nazer farm the workmen encountered a vein eight feet wide, and some of it is almost solid galena. Men are still at work and have gone several feet into it; it looks like a permanent vein.

SUMMIT COUNTY.

The Jupiter mine, in Thayne's canyon, seems in a fair way to become a big mine. Ore of high grade is being mined and several tons are in the bins awaiting hauling to the samplers. Ore has been opened up in several places. The main question is to get the mine in shape for regular production. The management has bought the machinery from the old Loring mill, formerly in Woodside canyon below the King, and it will be removed to the Jupiter.—Boilers for the new steam-plant at the Nelson property in the Elkhorn district have been taken over with the remainder of the equipment to be installed.—Work at the Uintah-Treasure Hill property is going on steadily, and the ground is opening up encouragingly.

TOOELE COUNTY.

E. D. Carmon, superintendent of the Polar Star mine in the Clifton district, reports conditions prosperous in that portion of the Deep Creek district. He says a new adit is to

be driven on the Polar Star which will tap the orebodies developed in the shaft.—Good reports are coming from the Gold Hill mine, which is being developed under the direction of Duncan McVichie.

WASHINGTON.

OKANOGAN COUNTY.

(Special Correspondence).—Munro Harman manager of the Ruby mine, at the base of Mt. Chopaca, reports that he is taking out rich ore and will ship on completion of the Vancouver, Victoria & Eastern Railway.—J. J. Bennett, who bonded the Kimberly group several months ago, has organized a company in Ohio and calculates to begin operations in two weeks.

Loomis, June 30.

SNOHOMISH COUNTY.

The Supreme Court of New York State has handed down a decision in a case involving the mining property known as the Pride of the Mountains, situated in Monte Cristo district, which has been before the courts for 14 years. The decision finds for the plaintiffs, in the sum of \$175,000. The Pride of the Mountains mine was sold by the late Hiram G. Bond, Wilmans brothers and Edward Blewett, to Colgate Hoyt and Charles L. Colby, agents of John D. Rockefeller, and the suit was brought against Colby as such agent. The consideration was to be \$350,000, of which \$175,000 was to be paid in cash and the balance was to be paid out of the proceeds of the mine or by the purchasers; in the event of the \$175,000 remaining unpaid after a certain period, the property was to revert to the original owners, plaintiffs in the suit. More than 150,000 tons of ore, which yielded returns of from \$10 to \$20 per ton, in gold, silver, copper and arsenic, were taken out.

CANADA.

BRITISH COLUMBIA.

In the Slocan, lessees of the Queen-Dominion will ship another car of ore. Boulders of ore weighing over a ton are being sluiced out at the Wonderful mine.—Ore-bins at the Bosun Landing are completed, and the construction of the tram line has commenced.—Two cars of ore are ready for shipment from the Index mine, up the south fork of Kaslo creek. A fine body of ore was struck a few days since.—Recent shipments were 390 tons of zinc ore from the Ruth to the Kootenay Ore Co. at Kaslo, and 40 of zinc ore from the American Boy to the Prime Western Co. of Gas, Kansas.—Several men are at the Monitor loading ore from the dumps for shipment to Rosebery. Ninety-seven tons went down last week and steady shipments are being made.—James Cronin, manager of the St. Eugene, has been making an examination of the Eureka and has put several men to work.—A rich strike is reported from the McAllister group up the north fork of Carpenter creek. The ore assays over 1,000 oz., mostly wire silver embedded in quartz. Great care has to be taken in handling the rich pay-streak, as it crumbles easily.

It is announced by A. B. W. Hodges, superintendent of the Granby Consolidated Co., that from this time forward work will be steadily prosecuted on the new main shaft at the Granby mines, which, it is estimated, will cost \$100,000. It will be known as the Victoria shaft. For some months two diamond-drills have been at work on the surface and underground in the Granby mines, and the situation selected is near the compressor building, where both the C. P. R. and Great Northern can readily run spurs to the crusher and ore-bins. Surface work has been started; when completed, the mine will have facilities for taking out from 4,000 to 5,000 tons of ore per day.

MEXICO.

JALISCO.

One of the most important mining deals recently made at Guadalajara is the transfer of El Favor mines in the Hostotipaquilla district of Jalisco to Makeever Bros. of New York. The deal involves the investment of \$250,000 gold. An American company, to be known as the El Favor Mining Co., will be organized at once with a capital of \$3,500,000, to take over and work the mines.

The mines were secured by Makeever Bros. from W. R.

Ramsdell and associates, and Carlos Romero. Mr. Ramsdell and associates purchased El Favor mines proper about five years ago, and they will now become interested in the new company. For several years Mr. Romero has held continuations of El Favor veins. The mineral land included in the transfer amounts to 152 pertenencias, or 376 acres. El Favor mines are the oldest in this part of Mexico, and the old workings are very extensive. They adjoin the Tamara y Anexas of Carlos Romero and the Solomon of Martinez Bros., both bonanza properties. Years before the Spaniards appeared the mines were opened by the Cora Indians, and when the conquistadores invaded that section of the country and began the confiscation of Indian mines, the Coras fought them to retain possession of their property. The fighting continued for many years and the Coras were always successful, the mines never passing into the hands of the Spaniards even for a limited time. Up to the time of the purchase by Mr. Ramsdell and his associates the mines were owned by Indians and Mexicans, and only primitive mining was done. Only rich ore could be handled, and there is a dump of 30,000 tons from the old workings that averages \$24 per ton. The old workings consist of a main adit and about 600 ft. of drifts, stopes, and cross-cuts.

GUANAJUATO.

The sale of the San Cayetano mines, six miles north of the city of Guanajuato, has been practically concluded. The purchasers are English parties, and the deal was made through the Mineral Development Co. of New York, which is already interested in the Guanajuato district. A partial payment has been made, and it is stated that the final payment will be made soon. It is understood that the transfer involves more than \$100,000. The San Cayetano mines have been owned for many years by the United Mexican Mines Association, Ltd., of London. With the conclusion of the San Cayetano sale, this corporation will go out of existence. It was originally organized in 1814, and became extensively interested in mines in different sections of Mexico. With the exception of the San Cayetano, all its holdings were disposed of several years ago.

ZACATECAS.

L. Maurice Cockerell, for the last two years general manager of the Mezquital Gold Mines, Ltd., the English company operating the gold mines and stamp-mill at Mezquital del Oro, has resigned. He will leave the mines as soon as his successor, a mining man from Australia, reaches there. Mr. Cockerell will go to England in August, and on his return to Mexico will devote his attention to other mining interests. The work of unwatering the lower levels of the Mezquital mines, which was started some time ago, will be completed in about two weeks. Production will be then resumed, and the 50-stamp mill, which was shut down pending the unwatering, will be again placed in operation. A Cameron pump with a capacity of 250 gal. per min. is being used to unwater the lower levels, which are about 750 ft. below the surface.

AN English imperial gallon weighs 10 lb., but the standard gallon used in the United States weighs but 8½ lb. or 7½ gal. per cu. ft. This works out to 240 gal. per ton of 2,000 pounds.

IF we assume the weight of brick-work to be 120 lb. per cu. ft. and that it will begin to crush under 700 lb. per sq. in., then a brick-wall of uniform thickness would have to be 840 ft. high before the bottom courses would commence to crush from the weight of the brick-work above. Average sandstones, weighing 145 lb. per cu. ft., would need a column nearly 6000 ft. high to crush the bottom stones.

PASSENGER platform-elevators in buildings should be designed for 80 lb. per sq. ft. of platform area or 150 lb. per passenger. Generally the local ordinances limit the car speed, as in New York City, to a maximum of 400 ft. per min. for cars which stop at every floor, and to 500 ft. per min. for express cars, those which go to two-thirds of their travel without stop. Four hundred feet per minute is about as high a speed as the average human system can stand without unpleasant sensation and is ample for the best schedules.

Personals.

O. H. FAIRCHILD is at Denver.

J. J. MAY has returned from New York to Denver.

A. B. FRENZEL has returned to Denver from Salt Lake.

J. H. ROBESON, of Denver, is in Arizona on professional business.

A. F. HEWITT has returned to Denver from Quartzsite, Arizona.

L. H. L. HUDDART has arrived in London from Southern Nigeria.

EUGENE BRADEN has returned from a short trip to Helena, Montana.

W. L. McLAUGHLIN has returned to Deadwood from Pittsburg.

JOHN PENBERTHY is on a visit to Redruth, Cornwall, from Bolivia.

W. FAY BOERICKE is prospecting in the region near Fairview, Nevada.

RICHARD A. PARKER has returned to Denver from British Columbia.

WILLIAM H. WASHBURN has gone from Fairbanks to Nome, Alaska.

GEORGE A. SCHROTER was married on July 1 at Brooklyn, New York.

D. M. RIORDAN is at the Bully Hill mine, in Shasta county, California.

P. G. LIDNER has returned from examining mineral lands in Santo Domingo.

W. B. PATRICK, of Denver, is visiting San Francisco, on his way to Nevada.

E. F. WETTLER, of St. Louis, is registered at the Baltimore hotel, San Francisco.

J. M. FOUSE has come from Denver to study dredging methods in California.

FRED B. REECE is with the Bunker Hill & Sullivan Mining Co., at Kellogg, Idaho.

FRANK COGILL, Secretary for Mines in the Gold Coast Colony, is visiting England.

J. V. N. DORR is supervising the construction of the Mogul mill, at Pluma, South Dakota.

ALFRED JAMES arrived on July 4 at Vancouver from Australia. He is now at Berkeley.

FRANCIS L. BOSQUI leaves on July 12, to make a metallurgical investigation at Denver.

JOHN ARTHUR has been appointed manager of the California mine near Sumpter, Oregon.

JOHN H. HUDSON, Jr., has his office now with W. R. Grace & Co., at Valparaiso, Chile.

W. C. OREM has returned to Salt Lake, from an inspection of mines in Mason Valley, Nevada.

HERBERT HAAS has gone to Torreon, Mexico, with the Compania Metallurgica de Torreon.

CHARLES MAGILL has resigned the management of the Guadalupe mine, at Inde, Durango.

M. M. HOWE, is manager of the London mine in Hoosier gulch, in Summit county, Colorado.

W. M. TURNER is superintendent of the Green Mountain Co.'s new mill at Silverton, Colorado.

H. A. SHIPMAN and R. J. GRANT have returned to Denver after an extended trip through Nevada.

CHAS. A. DEVLIN, of Boise, is investigating mines at Hailley in the Wood River country of Idaho.

EDWIN E. CHASE has returned to Denver from Mexico. He will proceed to Ely, Nevada, at once.

JAMES W. MALCOLMSON has returned to El Paso from an inspection at Tuxpan, in Jalisco, Mexico.

ERNEST LEVY is about to go to Australia from London, in the interest of the firm of Hill & Stewart.

E. F. STAPLES has been at Kelvin, Arizona, making examinations of lead, copper and tungsten mines.

J. CROWTHER, professor of metallurgy in the University of Adelaide, is on a visit to his home in England.

LEMUEL KINGSBURY is manager of the Summit and Buffalo placer mines, near Breckenridge, Colorado.

W. H. LINNEY is superintendent of the Nipissing Gold Mining Co., in Cobalt district, Ontario, Canada.

FOSTER HEWETT, of the Pittsburg Testing Laboratory, Ltd., was in Denver on his way home from Peru.

G. C. KLUG has resigned as general manager of the Boulder Perseverance mine at Kalgoorlie, West Australia.

A. L. WRIGHT, manager of the Bradley Engineering Co., of Spokane, was in Denver last week on his way East.

L. PITBLADO is in charge of the copper smelting operations at Capillitas, Province of Catamarca, in the Argentine.

JOHN E. PORTER has returned to Berkeley, from an inspection of his copper mine in Mariposa county, California.

R. S. BAVERSTOCK has returned to Los Angeles from an examination of scheelite deposits in Kern county, California.

G. G. HEWETT has returned to Colorado Springs from a professional trip to the new camp of Nuevo Leon in Mexico.

A. BOSCH is at Berlin and will proceed shortly to southwest Africa, as metallurgical director for the Otavi Mining Company.

LANCE C. GILLIAM, of the firm of Thompson & Gilliam, Los Angeles, is in Lower California, where he is examining a placer area.

F. LYNWOOD GARRISON has just returned to Philadelphia from a three months' professional trip in Missouri, Colorado, New Mexico and Arizona.

DANIEL GUGGENHEIM, accompanied by engineers of the American Smelter Securities Corporation, leaves Vancouver on July 10 for an inspection in Alaska.

ARTHUR S. DWIGHT has resigned the general management of the Greene Consolidated Copper Co. He has left Cananea for Joliet, Illinois, on his way to New York, where he will take a well-earned rest.

HUGH R. VAN WAGENEN, of Denver, one of the graduates this year from the Colorado School of Mines, has taken the management of operations at the silver-lead mines in Castle Dome district, Arizona, and is actively engaged in reopening those once noted properties.

Obituary.

GEORGE H. ROBINSON died in New York on July 3, at the age of 53. As a mining engineer, he was one of the foremost members of the profession and leaves his mark on the development of Alaska, Colorado, Montana, and Utah. Born in Ohio, he possessed the ability and energy that have given distinction to so many men from that State. In the early days of Leadville he was agent for David Moffat and also for Tabor. Later he became manager of the celebrated Drumlunnon mine, of the Montana Gold Mining Co., at Marysville, Montana. Then he moved to Salt Lake City and went into general practice, with marked success, being connected, in an advisory capacity, with several important mines. When F. Augustus Heinze got into his complex litigation at Butte, he needed a first-rate man to advise him in regard to the mining geology involved in his lawsuits and he engaged George Robinson, who exhibited great ability in several big cases. He severed active connection with Butte mining about three years ago and became interested in several important mining ventures, one of the most promising of which is the Britannia copper mine, on the coast of British Columbia. In many respects he illustrated the qualities, such as business insight and wide-awake energy, that have given the American mining engineer a leading place. Speaking generally, he was a particularly well informed and agreeable man, possessed of a distinct personality, which will be widely regretted throughout the West.

W. H. HARDY died at Whittier, California, on June 23. He was a pioneer in the Southwest, establishing an important trading post at Hardyville, on the Colorado river in Arizona in early days, and doing much to aid in the development of the mineral and other resources of that Territory.

Dial Alarm Indicator.

The accompanying illustration shows the Bolthoff Dial Alarm Indicator. The indicator is equipped with a bell which is struck by hammers at every point desired, giving a single stroke signal. The usual arrangement is to have the bell strike as each level is approached in both the upward and downward course of the cage. It may

Dial Alarm Indicator With Exhaust Control Attachment.

also be equipped with an exhaust-control attachment, as shown in the illustration, which serves as a safety stop, closing the exhaust-control and stopping the engine when the cage has reached the danger point. This dial alarm indicator may be attached to any kind of hoist and further particulars will be supplied by the manufacturers, The Hendrie & Bolthoff Co. of Denver.

ALUMINUM OUTPUT SMALL.—The increasing demand for aluminum and the increased price of copper, has created a shortage of aluminum. The fact that many parts of automobiles, motors, cables, etc., are now being made of aluminum, has served to increase the demand until it is fully 20% greater than the production. It is figured that the Hall patents on the manufacture of aluminum will soon expire and this will increase the output past the demand. There is not much danger of this. If the production is increased, the consumption will grow in proportion. Aluminum is an ideal metal for some lines of manufacture. —*American Manufacturer.*

Publications Received.

Bulletins No. 30 to 34 inclusive, of the Corps of Mining Engineers of Peru, Lima. These volumes are in Spanish and are well illustrated, describing the mineral resources of that southern Republic.

Dividends.

On July 5, the Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 106 of \$180,000, making the total paid since January 1, 1906, \$1,260,000, and total to date \$6,786,000.

The Osceola Consolidated Mining Co. has declared a semi-annual dividend of \$6 per share payable July 27. The previous dividend in December, 1905, was \$4, and a year ago one of \$2 was declared.

The directors of the Tamarack Mining Co. have declared a semi-annual dividend of \$2. The last dividend was \$3 per share.

Trade Treatises.

THE INGERSOLL-RAND Co. of New York have issued catalogue No. 383, describing and illustrating the Temple-Ingersoll electro-air rock-drill—an air-drill driven by electric power.

HARRON, RICKARD & McCONE, Pacific Coast representatives of the Ingersoll-Rand Co., of New York, have issued a little pamphlet entitled Compressed-Air Pumping Systems. It describes the lifting of water and other liquids in pipes by means of compressed air applied in a new way.

DE LA VERGNE MACHINE Co., of New York, has issued a 48-page pamphlet describing various types of horizontal and vertical ammonia-compression refrigerating machines and equipment for ice plants, breweries, packing houses etc. The book is illustrated by many fine half-tones.

One of the original fan system heating and ventilating plants installed by the BUFFALO FORGE COMPANY in Buffalo was placed in the first works built by the Geo. N. Pierce Co., on Hanover St., a quarter of a century ago. The Pierce buildings have long been overcrowded, and since the fire, plans have been drawn and contracts let for a magnificent group of buildings on the Pan American site at Elmwood Ave. and the Belt Line, which in equipment and construction will be unexcelled in this country. The entire contract for heating and ventilating these buildings has been awarded to the Buffalo Forge Company.

ALLIS-CHALMERS Co. has issued Bulletin No. 1051, describing and illustrating its alternating-current generators of the belt-driven type.

Commercial Paragraphs.

THE BALAKLALA CON. COPPER Co. at Coram, in Shasta county, Cal., is building 3½ miles of Bleichert tramway furnished by the Trenton Iron Works Co., of Trenton, New Jersey.

THE INGERSOLL-RAND Co. of New York, through its Denver agents, Cary and Fielding, is supplying the Government with a 700-ft. compound steam and air compressor for use in the Gunnison tunnel, making three in all of this type of machine to be applied.

During the annual meeting of the American Institute of Mining Engineers which is to be held in London this year, commencing on July 23, those in attendance are cordially invited to make their headquarters at the London offices of the ALLIS-CHALMERS COMPANY, 533 Salisbury House, Finsbury Circus, where mail may be directed in care of Mr. J. W. Young, manager, who is also a member of the Institute.

THIS has been our best season in contractors' locomotives and we have probably built more than any other concern in the country. We have not been able to make

shipments quite as promptly as we should like to have done, but we are now nearly caught up and are just waiting for that inquiry of yours. We build the dinkies in all sizes—for burning coal, wood or oil,—and we think we put up a mighty good machine.—No, we do not build the cheapest locomotive, but some of our customers say it is the very best on the market when workmanship and hauling capacity are considered.

If you want information write to us at our home Office or to our

Editorial.

THE AMERICAN CONSUL at Rio Janeiro writes to warn people against the diamond mining schemes in Brazil. It appears that stock in several such companies is being offered to the unsuspecting public, not only in this country, but also at London. It is said that most of these diamond enterprises are frauds, organized by clever promoters, who make use of vague statements appearing in local papers.

THERE is a lady prospector in Nevada and she is said to be the only licensed lady broker in the sagebrush State. Already we learn that this feminine embodiment of Western energy has located "six beautiful claims, one of which has a red and white porphyry dike running through it." We expect even better results, such as a lacework of quartz seams or an insertion of calcite; if the lady prospector will but skirt the foothills she may find that the strata are pleated into lovely folds and that the limestone forms a ruching around the rhyolite. Beautiful is no name for it; the desert ought to blossom like the rose beneath her fairy steps and the geology of Nevada ought to become as dainty as an Easter hat.

WE TAKE PLEASURE in publishing an authoritative article on 'Mining in Korea,' by Mr. J. H. Curle, who writes to us from Seoul, the capital of that Japanese dependency. As yet, gold mining in Korea is identified mainly with the success of the Oriental Consolidated Mining Company, an excellently managed enterprise, with Mr. H. F. Meserve at the mine and Mr. Henry C. Perkins directing affairs at the home office, in New York. The Oriental Company has had the help of some of the most experienced men in the profession and among other things it has not made the blunder of introducing expensive foreign labor; it has trained the natives to become good miners. For this reason operating costs are extremely low and profits have been won from a low-grade gold ore.

A LOCAL PAPER states that "the people of Keswick are hopeful" that ore from a certain mine will be "run through the smelter" which has been idle for two years. The smelter is that of the Mountain Copper Company and it is idle because the people of Keswick and vicinity compelled it to close down by bringing black-mailing suits against the smelting company, alleging the destruction of valuable farms and timber-lands through fumes made by the smelter. The good people of Keswick have got their extremely valuable ranches to console them; and ranches, as we all know, employ a large number of skilled workmen, so that business ought to be flourishing at Keswick. You cannot eat your cake and have it. But we note that every time a new smelter starts, it is hailed as a benefactor to the community, until a few

millions have been invested locally, at which time one or two enterprising citizens come out with statements that their valuable hay-crop and timber-lands have been irretrievably ruined by the iniquitous smelter-man. Put a smelter at a distance from any farm and people will crowd around it, building up a community that will start a local agriculture to supply local needs—until such time as there is more money in litigation with the smelter company than there is in raising vegetables or growing hay.

THE ANNUAL REPORT of the Transvaal Chamber of Mines gives many interesting figures. The total amount distributed in salary and wages during 1905 was £8,762,344; of this, the 17,280 white employees at the mines received £4,778,191 in wages, and 1,975 members of the technical and clerical staffs got £821,675 in salaries; colored laborers, numbering 129,194, received wages amounting to £3,162,478. The total gold production since the beginning, in 1887, is estimated to have been £136,876,670; the output actually declared is £134,226,539, to which is added the undeclared yield during the war period. In ounces, the total output has been 32,223,486 fine gold. Production began, in 1887, with a yield of less than £100,000; increasing rapidly to £10,583,616 in 1897; to £15,141,376, in 1898; and then dwindling—by reason of the Boer war—until 1904, when it was £15,520,329. Last year was the record figure, £19,991,658, and this year will surpass even that prodigious production. The total dividends distributed during the 19 years from 1887 to 1905, inclusive, amount to £33,164,342. Seventy-four companies appear on this dividend list; the Robinson is the largest contributor with £4,514,688, the Ferreira comes next with £2,019,250, the Crown Reef has third place with £1,961,900, and the Langlaagte Estate is fourth with £1,692,880. The City & Suburban has distributed £1,462,913; the Bonanza, £1,255,000, the Geldenhuis Estate, £1,180,750; the New Primrose, £1,140,025; the Simmer & Jack, £1,041,461; and the Geldenhuis Deep, £1,035,000. Thirteen other companies have distributed over half a million each.

Mining and Metal Prices.

The cost of mining is a vital subject on which too much—if it be to the point—cannot be said. A thoughtful contribution, such as that of Mr. J. R. Finlay, on another page, is of the greatest service in clarifying ideas and we trust it will provoke further discussion in our columns, which are always at the service of the profession for such a purpose. Mr. Finlay brings forward an illuminating suggestion in regard to the relation between the prices of the useful metals and their degree of occurrence. On the face of it, the inference he makes seems obvious, for the cost of mining resolves itself into a series of efforts to get rid of the valueless portion of rock in which the particular metal lies encased. The same process is repeated in metallurgy, where, however, the intimate mixture of minerals constituting the rock as found in the mine is replaced by a chemical compound of metals and their salts; it is the metallurgist's aim to break up or modify that compound so that out of it is extracted, in the most marketable form, the particular metal or metals desired

by the operator. Viewed in this light, the 'resuing' of the Cornishman, who strips a vein of rock so as to blast it down clean, is the most fundamental of all the series of operations that constitute mining and metallurgy. The next stage is sorting, preferably in the stope, so as to eliminate at once all unnecessary waste; and then at surface, whether by hand, aided only by a spalling hammer, or by the use of a rock-breaker followed by a picking-belt, increasing the speed of the operation and rendering it more mechanical. Whatever may be the skill and the science expended on the subsequent performances in mill or smelter, it is certain that the place to begin economy is at the very start—in the stope, and then at the ore-bin. This is a duty delegated as a rule to men who are not among the chiefs of a large staff; it is given to shift-bosses and foremen with whom directors and mine-owners fail to come in frequent contact. For this reason it is often overlooked or neglected. The economy of mining, like the structure of a building, must be well founded; it must begin at the first operation.

The cost of mining is interesting, because it is a prime factor in determining the profit to be won by the operator; but it is only one of the factors; the price which the metal will fetch after it is extracted, is equally decisive. In this connection it is interesting to note how the average prices of the useful metals rise and fall in company; the following figures are self-explanatory:

	1885	1894	1900	July, 1906
Copper—				
Cents per lb . . .	10.70	9.56	16.17	18.25
Lead—				
Cents per lb . . .	4.05	3.29	4.37	5.75
Zinc—				
Cents per lb . . .	4.41	3.52	4.30	6.00
Tin—				
Cents per lb . . .	19.58	18.08	29.90	39.25
Iron—No. 1 foundry Dollars per ton . .	16.00	11.87	13.00	17.75

Eleven years ago the prices of copper, lead, zinc, and tin were all much lower than they are today, but these four metals fell in sympathy during 1894, to rise again in 1900 and to reach record figures in the present year. The rise has been due to the tremendous growth of industry, more particularly the industrial expansion of the United States. The same cause influenced the prices of pig iron, which fell severely in 1894, as did the other four metals, simply because the crash of 1893 curtailed construction and manufacturing for the year or two following. Since then the country has seen a wonderful growth; copper, lead, zinc, and tin have benefited directly, and if the price of iron has not been as regularly on the increase, it is because of artificial conditions created by the tariff and the combination among the big ironmakers. The discovery of new ore deposits seems to have disturbed prices hardly at all, the exhaustion of mines having balanced the opening of new ones. In tin, the scarcity of the ore has produced an excessive rise, it is true, and in zinc, the discovery of new processes to treat low-grade material appears not yet to have overstocked the market; in copper and lead, the demands of manufacture have distanced production, despite increasing skill in extracting the metals from their ores. Particular conditions affecting the individual metals do not obscure, they only serve to emphasize, the broad fact that their value rises concurrently as the demand for them is created by the industrial growth of this and other countries.

By the Way.

In a little pamphlet entitled 'The Business of Contracting,' Mr. Ernest McCullough gives advice, some of which is applicable to mining operations. He says:

A good foreman—if he is not good he should not be employed—is a man who thoroughly understands the work in hand and who understands human nature. He must be able to get a day's work from his men and still keep from quarreling with them. If he is generally called by his first name by his men, and is found to go with the crowd to the nearest saloon at quitting time, it is doubtful if he ever gets the best results from the men under him.

Sympathy is a good thing, but the possession of a soft heart is bad. The frequent hearing of 'hard luck' stories from his men is a bad thing for 'the boss' and his interests. The labor unions recognize this when they say a man is outside the union when he is a boss.

A first-class foreman is generally 'Mr.' to his men. They know they can go to him with a recital of real troubles connected with the work and that he will make an honest attempt at relief. They know that family troubles are not to be mentioned to him. They know he has no patience with a man who is continually voicing his hard luck and troubles, for it all delays work, and he is employed to expedite work. They realize that he knows fully what a good day's work should be and that each man in the gang must give it or be fired. The feeling of the men may be one of respect, but it is certainly not love. Expressions of regret when he leaves are sincere only in proportion as their forecast of the character of the new foreman is favorable or unfavorable.

It is the foreman who makes the money on a job, and it is the foreman who loses it. Therefore the manager should be a judge of men, a thorough man in his knowledge of the business, and he should always insist upon documentary evidence when hiring a foreman.

The frittering away of small sums counts terribly. Good foremen are nearly as scarce as the proverbial hen's teeth, and it is unfortunate that the majority come from walks of life that forbid any intimacy or great show of friendliness on the part of their employer. Few of them are strong-headed enough to stand it. It is a fact that a foreman is seldom worth his salt after the second job and must be gotten rid of and go to work for some one else. If he is worth keeping for a third job he is likely to have in him qualities which will lead to his being safely intrusted with more important work or which will enable him to secure backing to go contracting for himself.

Many contractors lose money because they are under the domination of old employees, although they will not admit a fact which is patent to all their friends and sometimes to the most casual observers. The writer is not hard-hearted, but he never sends for a man when a new job is secured. If a man who has proven himself asks for a job he will give it to him. It is poor policy to send for a man and give him the idea that he is indispensable. It is well to be appreciative, but to too many men an appreciative pat on the back goes to the head like champagne. There should be a systematic method of keeping track of work done, so a daily comparison can be made of work done by different men.

It is good for a man to know his efforts are fully noted. He feels sure then he is getting a square deal and devotes his time to doing his work well and does not waste time trying to "get a stand-in with the old man."

Having carefully selected a foreman by examining closely into his record after sizing him up, the contractor must give him absolute control over his men. Never interfere and hamper him in any way. Keep close tab on all he does and insist upon him getting full value out

of his men. Look to him for results, and, if they are unsatisfactory, let him go in a hurry. When money is being lost on a job it is lost quickly. The writer respects his foremen by never sending to any gang a man fired from another. 'Fired from a gang, fired from the job' is the rule except in particular cases. It has happened that a foreman and some man in his gang have disagreed so that the man is fired. The foreman, however, has been manly enough to intimate that the trouble is personal and the man might work well somewhere else. When such a thing happens the man may be sent to another gang. Where such a rule is not observed, chaos would reign and no gang would be contented—the foremen least of all.

A foreman, like any workman on the job, should be spoken to only twice if he is not giving satisfaction; the second reproof to come in the form of an invitation to 'come to the office.' It should also be the last time he will ever be seen in the office of that employer. Sometimes a foreman over a certain gang seems to be lessening his output, but at the same time seems to be as earnest as ever. Before letting him go it is well to shift him to a gang of strange men. If the men are staying contentedly with a job it is bad policy to leave a foreman over the same men too long. As the men get better acquainted among themselves it often happens their efficiency is increased by reason of good-natured, friendly rivalry. If the men get too well acquainted with the foreman, or the foreman with them, there is a lowering of efficiency. A shifting of foremen occasionally is good, like the changing of the beats of policemen.

In the afterword which Winston Churchill substitutes for the ordinary preface, he states the truth exemplified in 'Coniston,' his latest novel: "Self-examination is necessary for the moral health of nations as well as men, and it is the most hopeful of signs that in the United States we are today going through a period of self-examination. We shall do well to ascertain the causes which have led us gradually to stray from the political principles laid down by our forefathers for all the world to see." A little later he adds: "To use a figure suggested by the calamity which has lately befallen one of the most beloved of our cities, there is a theory that earthquakes are caused by a necessary movement on the part of the globe to regain its axis. Whether or not the theory be true, it has its political application. In America today we are trying—whatever the cost—to regain the true axis established for us by the founders of our republic."

THE reproach has often been made that mining in the United States has been characterized by the most outrageous robbing of the deposits. That reproach is not now justified to the extent to which it was when gouging a mine to get rich over night was a very widespread practice. But the country at large, as the owner of the mineral resources of the public lands, has not only the right, but it is its duty, to check any such practices which dissipate a national asset. No private owner of mineral land in our older States, like Pennsylvania, will lease his land to one who exploits its mineral without stringent rules providing that the miner operate it in a workmanlike manner. The Government, as a partner in the enterprise of utilizing the mineral deposits of the national domain, should not alone draw a fair revenue, but should also act as a guardian of that mineral wealth against the reckless waste which has taken place in the past and against the indifference to the future which is only too common even today. *From Age.*

Special Correspondence.

LONDON, July 4.

At the last general meeting of St. John del Rey Mining Co., one of the directors mentioned that 60 years ago his father joined the company. From that time either his father or he had continuously held a seat on the board. They had seen three mines opened and two of them destroyed, and there had been many ups and downs in the price of the shares, which they had seen go up to £4 and down to 6d. For a mine of such longevity and 4,000 ft. deep, the record might reasonably be drawing to a close, but the chairman, in moving the adoption of the report and accounts, was able to show that the mine still had something to say for itself. In the past five years they had rejected on an average 6.3% of the mineral raised, and had crushed an average during each of those years of 148,000 tons. The gold taken from the mineral had realized £284,000, the yield per ton being 38s. 3d. Out of the profits each year they had averaged £11,000 on development and improvements of various kinds, and the balance of profit available was £61,000, with an exchange that averaged for the period 13d. per milreis. In the three years preceding, the average yield was 53s. 4d. per ton, and from the profit the average expenditure in development and work, some of which had fairly been charged to capital, was no less than £36,000, instead of £11,000; and yet there was a profit of £109,000 per annum. The exchange, however, was only 8d. But it was more than a question of exchange; it was well to remember that they had had poor mineral before in the long history of this mine. The latest advices from Brazil led them to infer that there were prospects of improvement. In the bottom of Level 14 there was a fair length of as good mineral as ever they had, and there was also an appearance of better mineral in the western end. The manager, Mr. George Chalmers, looked upon this as the apex of two good bodies, and when they went lower and were in the 15th level, the chairman said, they would know all about it. At all events, he, personally, was not in the least discouraged, bearing in mind that they had reserves amounting to 1,000,000 tons, and if they deducted 10% for rejection, they still had 900,000 tons of ore developed, and the whole of that development had come out of profits.

Another mining company of long standing, the Montana, held its annual general meeting—the 25th—last week. The chairman, referring to the litigation with the St. Louis Co., said he thought the shareholders must have been as surprised and as disappointed as the directors were when, after several days' trial, the jury awarded the sum of \$195,000 as damages against their company in respect of trespass on the compromise ground, and of ore supposed to have been gotten and worked out of the disputed area. They were advised that this decision of the jury was based upon misdirections in law, and that, in any case, the amount of the verdict was out of all proportion to the real damage. They thought, as in the past, they would receive substantial justice from the Superior Court of the United States, and with that object, they appealed to the Appellate Court of San Francisco. To enable this appeal to proceed it was essential to deposit security for the amount of the judgment. Fortunately, their policy in the past, of accumulating surpluses, enabled them to deal with the situation promptly and satisfactorily. They had lodged security for the necessary bond by depositing over £35,000 worth of cash assets, so that when the appeal was decided, if the judgment was in favor of the company, their funds would be released, and there would be ample in hand for development purposes. Turning to the work of the past year, the chairman pointed out that the Drumlummon mine, as a producer, had nearly ceased to exist. The few lessees at work extracted ore to the value of \$35,000 only—a pitiable amount when compared with the big output of former days. The tailing plant had been their great source of earning. They had treated nearly 77,000 tons, which had realized \$150,000. The value of this tailing had been steadily diminishing, so that a profit of only 70c. per ton resulted from their treatment, as against \$1.35 in former days. With regard to the Nevada property, the development continued, and they had been able, out of the profits of working, to pay the cost of this development,

which exceeded £5,000, and to leave nearly £2,000 surplus. Their total charge on capital account to the Edgemont mine during the past year was only £1,200. They had treated 17,600 tons of ore for \$6.94 per ton; while the working expense was \$4.91, leaving a balance of \$2.03 profit per ton. In concluding his remarks, the chairman said it would be seen they had changed the centre of interest from Marysville to Edgemont. They had got, after many disappointments, a property which promised to produce a reasonable profit upon a reasonable expenditure of capital.

During the last financial year, the total receipts of the Progress Mines of New Zealand, Ltd., from bullion and other sources, amounted to £99,676; after deducting the expenses, a profit was left of £29,595. A slightly larger tonnage has been treated during 1905 than in the preceding year, the mill-rock crushed being 60,000 tons. The yield is less than last year, and the working cost is higher by 7d. per ton. The engineer, after making allowance for non-payable quartz, estimates the tonnage in sight in December last at 90,000 tons. A large amount of exploration work has been carried on at the 10th level during the last two years, with the object of finding the orebody, but the reef is broken and the ore patchy. Finally, the shaft had been sunk to another level, and a long cross-cut made to intersect the reef; the engineer now reported that the lowest level, has, so far, opened up in a promising manner, rather better than expected. The assays from one of the drifts are stated to average 11.59 dwt., in other parts varying from 1 dwt. to 24 dwt. per ton. Attention has been devoted during the year to the question of improving the extraction from the slime and concentrate. Mr. Alfred James has recently been at the mine to study the question. A large number of experiments are being conducted at the mine, as well as in London, on both the concentrate and slime, and improved results are expected.

The directors of Camp Bird have issued a report for the half year to April 30. During this period the mill crushed 29,080 dry tons of ore, and the profit at the mine amounted to \$538,437. The amount expended on construction was \$5,291 and on re-construction \$6,648. Dividends No. 17 and 18 were paid, absorbing £2,000. Cubic feet stoped, 261,009. Development work: In drifts 2,085 ft., raises and winzes 720 ft., and shaft No. 1 was sunk 247 ft. It is intended to sink to a depth of 937 ft. before opening out at the sixth level. Of the ore treated during the half year, about 41% was withdrawn from reserves in stopes. All work was suspended at the time of the snowslide on March 17, at which date the total ore broken in the mine amounted to 120,477 dry tons.

The estimated profit of Esperanza (Mexico) for the month of May is £80,656 as against £56,427 for April. Development work, 945 feet.

The Central Zinc Co., Ltd., has been started under good auspices, and with every prospect of becoming an important and successful enterprise. In the formation of the company no outside subscriptions were invited or accepted and an arrangement was made with Anthony Gibbs & Sons, who are the largest shareholders in the Sulphide Corporation, that they should underwrite free of charge to this company any shares which might be otherwise unapplied for. Of the 150,000 shares at £1 each, 110,000 have been subscribed for by the general body of Sulphide Corporation shareholders and the balance by the underwriters. The company is already operating a small plant at Swansea, and it is reported that arrangements have been concluded between the company and the Tees Conservancy Commissioners for the acquisition of a site near the mouth of the River Tees, north of the delta covering approximately 30 acres. The smelting works will give employment to between 500 and 600 men. They will deal, in the first place, with from 40,000 to 50,000 tons of zinc concentrate annually. Their output will be spelter and sulphuric acid, and it is expected that within a short time of starting operations, they will be in a position to duplicate their works. The ore, which is derived from the Broken Hill district, will be obtained from the Sulphide Corporation. Mr. H. M. Ridge, who has had considerable experience in the handling of Broken Hill ores, has been appointed general and business manager, while Mr. Emil

Herter, who has had a large experience in zinc distilling in Upper Silesia, has been appointed metallurgist and technical superintendent. Some trained furnace-builders have also been brought over from Germany on Mr. Herter's advice. A new industry will thus be created in the northeast of England, where larger quantities of spelter are employed.

Cornwall is not South Africa and the report of His Majesty's Inspector of Mines is not a Coolie re-patriation notice, otherwise the Home Office Blue Book, containing the report in question for 1905, would probably have been issued at an earlier date. In view of the increased activity in tin mining, the work-people employed make up a total less than might have been looked for. The average number of all ages underground for the year in Cornwall was 3,508, and above ground 2,770, which included 217 females. The Inspector (Mr. Joseph S. Martin) states that at the present time none of the tin mines are what can be called rich; but the price of the metal makes up for the deficiency. It used to be said that tin should be about £95 per ton, in order to enable Cornish mining to be moderately remunerative, and with lodes giving about 60 lb. of tin to the ton of stuff, that price should be satisfactory. The present general run of the mines is from 32 to 40 lb. of tin per ton, which, at the present price of black tin, works out pretty much the same. Mr. Martin reminds us that history is wont to repeat itself, and that in 1887 and 1888 the same prices were attained, and followed by a large slump from £170 to £78, in the latter year. The Inspector's report is of special interest at this time and merits a further notice in this correspondence.

JOHANNESBURG, June 18.

Political questions are uppermost in men's minds today. Before the end of the year it is probable that the Transvaal will launch out under responsible Government. The British are much exercised over the prospect, for it looks as if the Boers will gain a majority. This depression has driven and is still driving thousands of British voters from the country at a time when they are most wanted. The British still remaining are by no means united. The Boers, on the other hand, will present a solid phalanx. It is feared by many that the policy of the Boers, should they get into power, will be to play a waiting game. If they can continue the depression by driving away the Chinese and so get rid of the uitlander, they will be pleased. Their policy will be against the mining industry, some people declare; but I do not think these gloomy forebodings will come to pass. The Boers know perfectly well that without the mining industry the Transvaal would soon be a bankrupt country. They will play their anti-Chinese card with consummate skill, and hold this bogey over the industrial community. Probably the outcome will be a compromise between the parties. The Boers will consent to Chinese labor, provided their language is given recognition and they are allowed a big say in the educational questions of the country. Meantime the uncertainty of the political situation causes grave apprehension. Most people realize that without Chinese labor, expansion for the present is out of the question. It is feared that the new regime might vote against Chinese labor. The feeling of uncertainty is such that the record output for May of 461,202 oz. gold for the Transvaal has not cheered people much. There was an all round improvement, and at the present rate of working it is highly probable that the gold output for June will be over £2,000,000.

Another attempt is being made to do something with the Transvaal mineral industry, other than gold. This time it is asbestos. The Consolidated Gold Fields of South Africa have taken over from a syndicate an asbestos proposition. That this influential corporation has exercised its option is good evidence that the property will prove a payable one. The 'Sallies' scandal, however, has so unnerved people that they look askance at the mere mention of new enterprises.

The position of 'Sallies' has not improved. The latest returns are disheartening. Unless there is a speedy improvement, the 'Sallies' tin mine will be forced to close down. The most inexplicable thing in the whole wretched affair is the report on the property by Mr. R. J. Frecheville, whose big reputation as a mining expert induced many con-

servative people to consider 'Sallies' a promising proposition. The returns by no means bear out his report.

Progress is being made with the extension of the Johannesburg municipal electric tram-lines; before long the city will be well supplied with cars. This will be a blessing, as the chief reason heretofore for the exorbitant rents has been the poor transport service, consisting of obsolete horse-cars and dirty cabs. Had the electric trams been running ten years ago, as they should have been, thousands of pounds would have been saved to the mining community.

TORONTO, July 13.

The discovery of gold at Opastica lake, 75 miles north of Ville Marie on the Quebec side of Lake Temiskaming, has thrown Cobalt completely into the shade for the time being. The point of departure for the new scene of activity is the old French village of Ville Marie, a typical Quebec settlement, the neighborhood of which has for long been known as rich in mineral resources. Messrs. Renaud and Ollier, the fortunate prospectors who made the find, are residents of Ville Marie, and set the whole community wild when they returned from the north with samples of quartz carrying gold grains the size of peas. The French Canadian is usually regarded as a somewhat slow and unenterprising citizen, but there was nothing slow about the gait of the Ville Marie people when the news got around; quite otherwise. The prospectors returned with their samples to Ville Marie on July 6, arriving home at 5 P. M. By six o'clock a company had been organized and the president had left for Quebec city to secure 22 square miles of the territory adjacent to the find. Then the general rush set in—or rather two rushes. The poor prospector packed his kit with all despatch and struck the trail for the north. The well-to-do speculator put a wad of bills in the seat of his pants and took the first train for Quebec to secure a blanket claim. The law of Quebec Province differs essentially from that of Ontario. No discovery is needed to secure a mining claim, and anyone can take up as much land as he chooses by paying at the rate of \$5 per square mile. This secures him absolute possession for three months, and he can renew at the end of that term, giving the wealthy man a chance to blanket a large area, select the most promising spots, and do prospecting work at his leisure. Thus the whole territory for many miles around the Lake Opastica find has already been covered by these blanket claims and the poor prospectors who have gone in numbers from Ville Marie as well as from the Cobalt camp and other parts of New Ontario, will have very little chance in that neighborhood.

Cobalt is rather under a cloud at present so far as investment is concerned, or the development of new properties, by reason of the disquieting effect of the judicial decision against the White Silver Mining Co., their leases having been declared forfeited on the ground of fraudulent affidavits of discovery. Other large companies are in danger of having their titles attacked and the uncertainty of the situation has a disastrous effect in discouraging any heavy outlay on Cobalt properties until the question is finally settled. The stock market has been very dull lately, buyers having taken the alarm. There are a large number of actions against the Temiskaming & Hudson Bay, one of the oldest shipping companies, hanging fire, awaiting the decision of the Attorney General, whose consent must be obtained before suit can be brought.

Fresh discoveries on the Montreal river are reported. Samples of pure native silver have been secured from a claim about three-quarters of a mile east of Portage bay, giving promise of a rich mine. Ruby silver has been discovered between Gillies depot and Latchford.—The Wabi Cobalt Silver Co., when trenching on a new vein on its property in Lorraine township, struck a rich body of ore about two feet down carrying pure silver.—A. A. Cole, late engineer and assayer of the War Eagle and Centre Star mines, of Rossland, B. C., has been appointed expert mining engineer to the Temiskaming & Northern Ontario Railway Commission, entering on his duties August 1. In that capacity Mr. Cole will have supervision of the mining leases under the control of the Commission and see that the conditions are properly observed by the lessees.—A syndicate of Bal-

timore capitalists has purchased the White Lily mine in the Atikokan gold range from Messrs. Manion and Murphy for \$30,000, and will put up a \$10,000 plant.

DENVER, July 16.

Denver has put on her gala attire to welcome the Elks, who hold convention here this week. Political squabbles are relegated to second place, and the whole city seems bent on a good holiday.

Some fellows have laid out a town-site at Ilse and called it Spaulding. They have a pretty fair hot-air machine working over time at the town-site, but it looks and sounds trifling to one who has seen and heard some of those modern, improved, quadruple-expansion, hot-air engines at work on new town-site schemes in Nevada. I do not mean by this that I think there are no mines at Ilse—I have already stated that I thought the prospects favorable. The recent reports from the camp have, however, so evidently originated in the office of the town-site company that many people have lost interest in the place; this is a poor State for town-site booms. We don't stampede readily enough. It seems to take the smell of desert sagebrush to make that sort of thing profitable.

A discovery important to Clear Creek county has been made in the Waltham mill, at Idaho Springs, in finding out that Empire ores are readily treated by amalgamation, concentration and cyanide. A great deal of low-grade ore has lain unworked in the mines at Empire for a long time because it could not be treated profitably by any of the mills in the district. The Waltham people put up a little mill to treat some ores near Idaho Springs. They were not very successful. In looking abroad for ores to keep their plant busy, they tried some Empire ores with excellent results. Shipments have been made by Cutting & Trevillion, from the Pioneer mine; by Wing Bros., from the Gold Dirt mine; and by William Poulson, from the Empire tunnel; in each case the shipment weighed 110 tons. So successful were the results of these runs that the Waltham mill has contracted enough Empire ore to keep it running to full capacity for the balance of the year, and the owners—Tanner, Anderson and Carlson—are preparing to erect another mill nearer Empire. Moreover, the Gold Fissure mine is preparing to build a mill along the same general lines. There is also talk of a pyrite smelter at Empire, in fact land has been bought for a site. Of course the promoters of this scheme may have something new and wonderful in the line of pyritic smelters, but one cannot help wondering why they do not buy one of the plants that are already built; they could get their experience so much cheaper that way. There is also to be erected at Idaho Springs a new style smelting plant that will treat all kinds of ore for 40c. per ton. The hot-air blast is probably an important feature of this process.

Several rich discoveries have been made near Georgetown. The most important is the strike in the Sunburst, which is described as 2½ ft. of stuff that carries 600 oz. silver, 25% lead and some gold. F. L. Peek and D. W. Shepard are the lessees who made the discovery.—I noticed a couple of new locomotives going up the canyon for the new East Argentine railroad the other day. They were of the type that has three vertical cylinders on each side, the crank-shaft of which is geared to the drivers.

This year has been singularly barren of important mining transfers, so the news that a deal of some magnitude has really been closed at Central City is interesting and refreshing. Report has it that a party of Eastern men were brought out to Central City by Mr. Thompson, manager of the Fifty Gold Mines Co., and that before they left they took 600,000 shares of stock at 50c per share. Good work, Mr. Thompson! Any one that can sell 600,000 shares of stock in a Colorado mine this year must be a rustler.—They keep striking oil in new wells up in the Boulder field. Nearly every week I notice a little three-line article to the effect that so and so has got a flowing well. It would be a strange thing if that field should turn out to be a big thing, after its disastrous early history, and the hard turn-downs it has got from some of the wise ones. New and important strikes of oil in the Florence field ceased to interest the public years ago because they were all made by the United Oil Co., which simply meant more money for Rockefeller

and the Hill estate, but today comes the welcome news that Phillip Griffith, an independent operator, has struck a big flow at the depth of 2,400 ft.—There is more going on over at Red Cliff this year than for many a long year. This is due to the discoveries in the East Battle Mountain belt, and to the reopening of operations on the fissure veins of Eagle canyon.

At Cripple Creek a very important discovery has been made in Cresson Consolidated by Richard Roelofs, superintendent of the Bull Hill Mining & Development Co. He has lately opened up the big shoot of ore at the 700-ft. level, and finds it larger than ever. It is said to be 50 to 60 ft. thick—its length along the vein has not been determined as yet. The value is given as \$20 per ton.—The recent discovery in the Acacia is holding out better than anticipated. From the bottom of the Burns shaft (800 ft. deep) a cross-cut was made revealing six feet of ore, two feet of which averages \$360 per ton.—John T. Milliken, of the Golden Cycle, has bought 11,000 acres of land, including two coal mines, from the East Colorado Springs Land Co. The deal is the largest that has been consummated in El Paso county for several months. The consideration is given as \$200,000. This is the second case I have heard of, where a gold mine has bought a coal mine to insure a cheap coal supply for metallurgical purposes. The Camp Bird Co. bought a lot of coal land over in the Grand River field about two years ago. It does not mean that the coal situation in this State is so bad that operators are driven to buying coal mines to protect themselves, but rather that coal mines are so plentiful that a fellow might as well have one if he has any use for the product.—The developments in mining for tungsten in Boulder county are so good that the buyers estimate the value of the product will add another million to Colorado's mineral output this year.

CALUMET, July 14.

Every effort is being made to place the Winona mine in condition to produce ore. The principal work is the preparation of stopes in the ground tributary to No. 3, which opening will be the only source of production for the first few months. The sinking of No. 4 shaft to the fourth level will also be pushed. It is likely that the Winona's output will be handled at the Atlantic stamp-mill. That plant treated the Winona rock formerly, and as the Atlantic has no use for its mill at the present time, arrangements can easily be made. At the new No. 4 shaft a depth of 40 ft. has been reached. It is expected that the shaft will be opened to the third or fourth level in three months, as raising on the line of the shaft is in progress to meet sinking from surface. The raises will be started at the third and fourth levels, where cross-cuts are now being driven to the line of No. 4 shaft from the drifts extending to that point from No. 3 shaft. Several other drifts are being driven southward from No. 3, but the longest of them lacks several months' work of reaching the line of the new shaft. At the eighth level, the deepest in the mine, the drift south from No. 3 shaft is in 450 ft. The sixth level is ahead of the eighth, and the fifth and seventh levels south are the same length.

Owing to the scarcity of experienced millmen, the Victoria has been unable to operate its stamp-mill at night. As soon as enough men can be obtained rock shipments will be doubled. Nothing official has been announced regarding the mineral content of the rock stamped. In June the product was only about 25 tons of refined copper, but this month it is expected to exceed 75 tons. Work underground is being conducted with a view to enlarged production. The openings are nearly six miles in extent, and it is estimated that sufficient rock is blocked out to feed one head at the mill for four years. While it is not expected that the ore will average high in copper, the low operating costs resulting from the Taylor hydraulic power-plant should make the property profitable. Everything about the mine and mill is now being operated by means of power generated from the plant at Glenn Falls.—Since the Michigan has made arrangements for sending its output to the Atlantic stamp-mill, the Mass Consolidated will soon have the use of the head in its own mill that will be released by the former company. As the Mass Consolidated Co.'s new C shaft is

in use and rock shipments by rail are regular now, it can supply rock to a second head. The shaft is capable of furnishing enough ore to feed the other stamp.

Captain John Peterson, who up to a short time ago had been in charge of operations at the Winona mine since its opening under the present company, has been appointed mining captain by the Hancock Consolidated Co., and will be in charge of the underground work. The Hancock Co. is organizing its executive staff. A number of heads of departments at the Quincy mine have accepted positions with the new corporation. — The result of the stockholders' special meeting of the Quincy Mining Co. called August 8, in New York City, to act on the proposition of increasing the company's capital stock, will be awaited with interest, as the Hancock Consolidated Co.'s territory would prove particularly valuable to the Quincy. — The showing in the Adventure Consolidated Co.'s new No. 4 shaft continues to be excellent. The work at that point is being deepened steadily and there is no diminution in the copper content of the ore. — Sinking in the new shaft of the Superior property, in Section 15, is progressing, and the showing is better than was made at the same depth in No. 1 shaft. In the latter, sinking is now in progress to the fourth level. — Operations will be started by the Caldwell Copper Co., a subsidiary concern recently incorporated by the Calumet & Hecla interests, as soon as a diamond-drill outfit arrives. The tract to be explored adjoins the Rhode Island, and is traversed by the Kearsarge amygdaloid formation, as well as other lodes. — A core recently extracted from the diamond-drill hole of the Isle Royale Co., north of the new shaft, in Section 11, revealed excellent copper ore for a thickness of eight feet. The drill is being removed to a point south of the shaft where another core will be bored into the Isle Royale amygdaloid. — John L. Harris, superintendent, has put men to cleaning up and repairing around the surface of the Hancock Consolidated Mining Co.'s property. The necessary machinery for starting operations is being secured as rapidly as possible, and it is expected that the unwatering of the shaft will be begun in a short time. The Mineral Range railroad is preparing to build a spur to the mine. The old shaft and rock-house which surmounts the Hancock shaft will be torn down and replaced by a large modern structure, probably this summer. The timbering around the collar of the shaft will be repaired, and as the workings are drained of their many years' accumulation of surface water the timbers will be renewed.

A final dividend of \$1.643 per share in liquidation of the Dakota Mining Co. has been declared by order of the Houghton County circuit court. The company has 20,000 shares and the dividend represents the proceeds of the sale of the property owned by the corporation, which brought \$36,000. All that is now necessary for the holders of the old stock is to file it with the county clerk of Houghton county and he will pay what is due. It was decided two years ago after the corporate life of the company had expired, to wind up its affairs and declare a final dividend after the remaining property was sold. The matter went through the machinery of the court with the above result. Persons who saved their certificates of Dakota stock, which was considered worthless, will thus profit by their precaution.

Several parties of students and professors from Eastern mining colleges have been visiting the Lake Superior copper district the last few weeks studying mining, milling, and smelting methods in vogue at the local properties.

SALT LAKE, JULY 16.

A meeting of shareholders of the Mammoth Mining Co. called for July 14, has been adjourned to August 4, when the matter of transferring the property of the company to a proposed new corporation to be organized under Nevada laws, will come up, the object being to obviate State courts. The Yerington Copper Co. has been organized here to operate in the Walker River mining district, three miles north of Yerington, Nevada. The incorporators are: Charles N. Strevell, president; Joseph E. Caine, vice president; C. D. Rootledge, secretary; H. P. Clark, treasurer; who, with James H. Patterson, S. V. Derrah, D. E. McPherson, H. C. Edwards and L. R. Martineau are directors; they are Salt Lake men. — During last week on the Salt Lake Stock &

Mining Exchange, 203,501 shares of stock were sold for \$140,125, against 83,712 shares for \$23,984 during the corresponding week a year ago. — The Boston Consolidated Mining Co. will operate two shifts with the steam-shovel at its Bingham properties. A machine is now removing overburden and is handling between 1,500 and 2,000 tons per shift of 10 hours. — F. Augustus Heinze has not stated, as yet, to what extent he is interested in the Bingham Consolidated Mining & Smelting Co. He has visited all the mines and the smelter of that corporation and attended a special meeting of directors, at which Duncan MacVichie was made director, and H. L. Charles, of Butte, a member of Mr. Heinze's staff, was named as general manager. At this meeting, \$400,000 was ordered set aside for smelter betterments. Mr. Heinze has secured an option on a control of the stock of the Ohio Copper Co., and has agreed to expend \$50,000 in development of the Bingham property of this corporation. The Ohio mill is handling about 200 tons of ore per day, nearly all of which is mined in development. — The Phoenix mine at Bingham is being examined by engineers, who are said to represent parties who hold an option on the property. — The Holderman Filter Tank Co., of Salt Lake, which has a lease on the Manning mill-dump of the Consolidated Mercur Gold Mines Co., will start its new plant at Manning, Tooele county, this week. It was built to treat 120 tons daily. The dump contains 800,000 tons, which, it is estimated, will assay \$2.50 per ton. The Holderman people claim that 80% can be saved by their method of treatment. — The Honerine mine at Stockton has resumed production, the ore being taken from the mine through the drain adit. The mill has also been started. The company has expended \$1,250,000 in preparation and has an indebtedness of \$350,000. — Several mines of the Tintic district have reported dividends for this month. They are: Mammoth, \$20,000; Carisa, \$5,000; Uncle Sam Consolidated, \$5,000; Beck Tunnel Consolidated, \$25,000; Grand Central, \$15,000, and Victoria, \$10,000. The Utah mine of Fish Springs pays \$2,000. — Mine owners of Bingham and other camps still complain of a labor shortage, and the construction of the Garfield smelter, and the mills of the Boston Consolidated and Utah Copper Co. has been retarded. The smelter, however, is almost finished, and by August 1 the management expects to have the plant in blast.

Control of the South Columbus mine at Alta has been secured by Tony Jacobson, manager of the Columbus Consolidated Mining Co., and associates. The property adjoins that of the latter at Alta. — Track-laying on the main line of the Western Pacific railroad is proceeding westward from Salt Lake. The rails are laid to the vicinity of the new town of Garfield, 12 miles out. — Tintic district producers have failed, as yet, to induce the transportation companies entering that camp to make any reduction in the existing ore tariff to the Salt Lake smelters, but the matter is under consideration. — The Standard Copper Co., composed of Salt Lake and Los Angeles men, has been organized to operate a group of eight patented claims at Bingham. W. E. Hubbard, of Salt Lake, is secretary. — The output of the Carisa, in Tintic district, is now about 50 tons per day. The ore is shipped direct to the Salt Lake smelters. — Tintic ore shipments last week aggregated 104 carloads, the shippers and amounts being: Ajax, 1; Beck Tunnel, 4; Black Jack, 7; Bullion-Beck, 8; Carisa, 7; Centennial-Eureka, 25; Dragon-Iron, 9; Eagle & Blue Bell, 8; Gemini, 5; Grand Central, 8; Godiva (concentrate), 2; Mammoth, 4; May Day, 2; Scranton, 4; Sunbeam, 1; Swansea, 1; Uncle Sam, 4; Victoria, 6; Yankee Consolidated, 2.

The Colorado Mining Co. has decided to resume development. It owns three lode claims adjoining the Bullion-Beck Tunnel mine, and is owned by those who control the latter. Jesse Knight, of Provo, is manager. — At Alta, the Columbus Consolidated ore shipments are being made at the rate of 75 tons per day. The mill is working two shifts. — In a cross-cut from the 700 station of the lower adit of the Albion Mining Co., at Alta, a contact vein has been encountered, the ore being iron sulphide. From the main adit a raise is being made to connect with the bottom of an old shaft 150 ft. above. — Development is progressing in the Wabash, in Summit county, and the manager states that the contact vein will be tapped within 300 ft. — The output of the

Daly-Judge during July will equal that of June, when net profits of about \$75,000 were made. A raise is being driven in the vein encountered in the western part of the mine several months ago. A winze is also being sunk in ore. The shoot is known to be 275 ft. long and 20 ft. wide. The mill is treating a little over 100 tons per day, but the bulk of the proceeds comes from ore shipments.

In Iron county, the Jenny Gold Mining Co. has a three-foot vein of shipping ore at Goldsprings. The company is completing the patenting of its claims and will soon be in the market for a mill. Charles A. Short, of Goldsprings, Utah (via Fay, Nevada), is manager. — In Washington county, the Utah & Eastern Copper Co. has again started its smelter at Shem City. The plant has been closed down since the washouts of last May, when miles of the company's road was destroyed. A traction engine is used to haul freight to and from Acoma, the nearest railroad station on the San Pedro, Los Angeles & Salt Lake railroad.

BUTTE, July 14.

The Amalgamated Copper Co. is pushing development at many of its mines. Ore-bins are being built at the Berkeley and Buffalo shafts, and it is expected that ore will soon be hoisted at both mines. Development work continues at the Anaconda, Nipper, Parrot, Tramway and Snohomish mines. The Amalgamated properties are at present yielding 10,000 tons of ore daily, of which 6,000 tons are shipped to the Washoe smelter at Anaconda and 4,000 tons to the Boston & Montana smelter at Great Falls.

The Red Metal Mining Co. is now shipping its output to the Washoe smelter, including its concentrating ore. The latter was, until a few days ago, sent to the reduction plant of the United Copper Co. at Basin. This plant will continue to run on what ore can be furnished by the Lexington Co., but it is the intention to have the concentrating ore of the Davis-Daly Estates Co. treated there when that company begins production. The United Copper Co. also owns the new smelter built at Basin by the Basin & Bay State Co. some years ago, but which was never operated; the plant will be equipped so as to increase its capacity and enable it to handle the Davis-Daly and the United Copper ores. The Davis-Daly Co. had secured options on land on the Big Hole river, west of Butte, where it had intended to build a smelter, but the options will be allowed to lapse because of the arrangement just outlined.

Work has been commenced on the 3,800-ft. cross-cut which the Original Mining Co. is to drive for the Davis-Daly Co. from the 1,800-ft. level of the Original mine. It is announced also that four additional shafts will be sunk; the machinery has been ordered. Pending its arrival a temporary plant will be installed. The shafts are to be carried to a depth of 2,000 ft., and no cross-cutting will be done above the 1,000-ft. level. The company starts with a working capital of \$2,000,000, and owns about 30 mines, or portions of mining claims, some of which are partially developed, while others have produced good ore in the past. C. H. Palmer, formerly general manager of the Butte & Boston Co., is general manager of the Davis-Daly operations.

F. Augustus Heinze has made his first payment of \$172,000 on the Stewart group of mines in the Coeur d'Alene district of Idaho, in which he recently purchased a controlling interest. Butte mining men are increasing their interests in the Coeur d'Alene, encouraged to do so by the enterprise of Mr. Heinze.

The electricians of the Amalgamated, Red Metal and North Butte mining companies went on strike on the first of May for an increase in wages. For the first time in the history of mining in Butte the companies united in resisting the labor demand with the result that the electricians lost their strike, and a few days ago called the contest off, returning to work under the old conditions. — A spur railroad track is being built to the Six O'Clock group of mines, which is being developed by the Butte Copper Exploration Co., for the purpose of hauling coal and supplies. The shaft is now 725 ft. deep, and sinking will be continued until a depth of 1,000 ft. is reached. No cross-cutting will be done above that point. — The East Butte Mining Co. will have its new hoisting engine ready for operation in a few days. The second shaft being sunk at the southern end of the property is the largest in the Butte district, and has been

opened to a depth of 200 ft. It will be carried down 1,000 ft. and connected with the main working shaft at the north end of the company's property.

Another company is being organized in Butte to explore and develop a number of mining claims on the east side of Butte. The organizers already have under control or option about 30 claims, most of which belong to W. D. Thornton, president of the Raven Mining Co., and a heavy stockholder in North Butte and Butte Coalition companies. Only one of the properties in the group is a producer. The Bertha mine was worked by tributaries, and recently they opened a good body of copper ore, but did not have a long-time lease on the mine, and shortly after the strike was made they were notified the Bertha would go into the new company and that they would have to stop work. Associated with Mr. Thornton are officials of the Amalgamated, Raven, and Butte Coalition. — In the Tzarina mine, southwest of the city, high-grade silver and gold ore has been struck, the average of several shipments being \$150 in silver and \$50 in gold per ton. The Tzarina is owned by James A. Murray, a banker, and is worked under lease.

The stockholders of the Butte-Milwaukee Copper Co. have elected John F. Cowan, B. E. Calkins, C. H. Smith, W. C. Siderfin and John N. Kirk directors, all Butte men, but it is understood an Eastern man will be substituted for one of those elected. A minority interest in the company was sold some time ago, and with the financial assistance thus received the company will be able to push development and take up the options on the Bird, Colonel Sellers, and Florence claims, as they become due. The company owns and has paid for the Pollock, upon which work was begun a week ago. The shaft on the Pollock is down 350 ft., but no stoping has been done below the 250-ft. point. From the upper levels, years ago, \$400,000 worth of gold and silver ore was mined. The Pollock has four veins traversing its entire length, only two of which have been opened. The mine is being unwatered and the company will explore the ground at the 350-ft. level, and at the same time sink the shaft. It is the general opinion that with a little more depth the silver veins of the Pollock will be found to turn to copper, and it was because of this belief that the Butte-Milwaukee purchased the Pollock. In addition to its Butte holdings the company owns nearly 100 acres of mineral land in the Argenta district, Beaverhead county, Montana, adjoining the properties of the Butte-Argenta Co. The latter is engaged in development work which will test the value of its own ground as well as that of the Butte-Milwaukee Co. Near the surface the Argenta ores carry silver-lead ore, mixed with iron, but as depth is gained the lead and silver are replaced by copper.

There has been no change in the position of the Raven Mining Co., and from present indications it will be a long time before access into the Snoozer mine will be obtained again. The Amalgamated Co. seems determined to keep the Raven out. Its first move was to take from the Raven the working shaft, which it was using under a verbal lease, and next it made a claim of ownership of the apex of the discovery of the Snoozer, its most important vein. With no shaft and a threat of injunction proceedings, the Raven was powerless, but still its officials talked about opening a shaft on the Snoozer and sinking it to the orebodies on the 1,500-ft. level. Should the company determine to do that, there is little doubt that the Red Metal Co., which owns a small interest in the Snoozer, would withdraw its consent to the mine being worked by the Raven Co. Under the conditions it is not probable that the Snoozer will ever be worked again by the Raven Co., unless the latter becomes an asset of the Amalgamated or Butte Coalition Co. The Raven Co. owns the Raven mine, upon which there is a shaft 700 ft. deep, equipped with a good surface plant, but the Raven claim has not yet reached the producing stage, though a copper vein has been opened on the 700 level. Owing, however, to the close relationship between the head officials and principal stockholders of the Raven Co. with the leading spirits of the Amalgamated and Butte Coalition companies, it is not likely that the Raven Co. will do anything that the two other companies do not wish it to do. It seems to be the general opinion in Butte that a new company will absorb not only the Raven and Red Metal interests, but will also take in the Old Glory Mining Co., which owns a mine adjoining the Snoozer, and which has made claim to one of the Snoozer veins.

CANANEA, Mexico, July 15.

Great activity is being manifested in the Cerro Tordillo district, which is situated about 35 miles east of Cananea. There are two large companies operating there—the Brooks Consolidated Copper Co. and the Union Consolidated Copper Co. Both of these companies have developed large bodies of copper ore which assays from 8 to 25% copper and from 20 to 90 oz. silver. A syndicate of mining men has been formed to acquire ground in that district and last week denounced about 300 acres, between the properties of the two companies named above. Owing to the good showing obtained by the companies already operating in this locality, there has been a rush and a great number of small claims have been taken up in the vicinity of the larger holdings.—The Arizpe Mining Co. has commenced development on two of its six claims and is obtaining good results. This company owns nearly 1,500 acres of mineral-bearing land 17 miles southeast of Cananea. The holdings include the Alacran, the Palo Seco, the Rey de Cobre, the Princesa, the Sevilla and the Victoria claims. A mill-run from the Sevilla gave 79 oz. silver, 4% copper and 0.5 oz. gold. A mill-run from the Victoria returned 15% copper and 20 oz. gold. Both of these claims cover large and well-defined lodes, some of which are more than six feet wide. Ore is being shipped from the Alacran claim and is giving net returns of about \$70 per ton at El Paso smelter. One car a week is the regular shipment. About 500 ft. of development work has been done on the Rey de Cobre and this has exposed a large body of low-grade sulphide, which gives average assays of 5% copper.

The Picacho Gold Mines Co. is installing heavy machinery over shafts No. 1 and 2 and is setting up an air-compressor capable of running 14 drills. This is the well-known mine which the Phelps-Dodge Co. has worked for the past five years. It was bought a few months ago by the Clancy Bros., of Detroit, after an investigation of the property which lasted over six weeks. The new management estimates that there is \$500,000 worth of ore on the dumps and over \$1,000,000 in the mine already blocked out. This ore will be treated at the Oro Maximo mill, which is two miles from the mine, and the management is making every effort to be ready to ship 100 tons per day to the mill as soon as it is completed. The mill was designed by W. H. Holms, of Mexico City, and embodies several new ideas; it is estimated that the ore can be concentrated for 80c. per ton, and as it averages about \$50 per ton, large profits are expected.

Ore assaying 18% copper has been struck in the Oversight mine of the Cananea Consolidated Copper Co. The strike is at a depth of 800 ft.; the drift is in this ore for 40 ft. and it is expected that this will develop into one of the greatest orebodies yet discovered in the camp. The breast of the drift is 6,480 ft. from the portal and will connect with Adit No. 7 in 800 ft. Ore assaying six per cent for the entire length of the drift on the 200-ft. level of the main shaft of the Henrietta mine—that is, for 160 ft.—is reported and within the next few weeks this mine will be one of the largest producers of the Greene properties. Air-drills and compressors are being installed and the work will be pushed. The building of four new McDougal furnaces and a new stand of converters will be commenced in August and it is expected that this new equipment will allow the smelter greatly to increase its output. The present reduction plant is undergoing a thorough overhauling and it is expected that it will be in first-class condition by the end of July.—

Announcement has been made privately that the America mine, owned by the American Mining Co., of Los Angeles, has been sold to Thos. F. Cole for the sum of \$2,250,000 cash, and the buyers have already taken possession. A new body of chalcocite was opened up last Sunday, and subsequent work shows that it is an immense deposit and is the richest ore that has been found in this camp. About one year ago this mine might have been bought for considerably less than \$100,000, but the great development under John Talbot, the superintendent, has raised it to its present value.

The titles to the Calumet & Sonora Mining Co.'s properties have been obtained and the development work will commence in a few days. These titles were obtained at the City of Mexico in the record time of 18 days.

Mining Summary.

ALASKA.

John H. Hughes has left Seattle for Alaska, accompanied by an engineer to make the surveys for a nine-mile ditch to carry water to placer property which he owns on Hearst creek in the Fairbanks district.

R. M. Oderkirk, Joe Herzog, and Charles Herzog, of Seattle, have returned to Seward from a trip to the Susitna country, and the country northeast of Mount McKinley, and report great quartz veins in that region. The ground is very mountainous but creeks afford valleys along which travel is not difficult in winter. In the summer, however, the region is frightful to travel over, owing to the lack of trails and the fierce rushing of the glacial streams whose source is on Mount McKinley. "With Government aid in establishing suitable trails in this section, it will undoubtedly prove to be a very rich mining district," said Oderkirk. Three large rivers were found, which were not recorded on any available maps. The party named three creeks in the district which they believe had never before been seen by white men. The names given to the creeks were Costello, Colorado and Ruby. On these creeks quartz claims were located by the party. The quartz contained a large amount of iron pyrite, which assays \$77 gold. While the Oderkirk-Herzog party was in that district, Blankenship, Rody & Hickman arrived and located five claims.

ARIZONA.

GRAHAM COUNTY.

(Special Correspondence).—The Tucson, Congress and El Senado mining claims, owned by Marcus A. Smith and L. O. Cowan, of Tucson, have been acquired by an English syndicate for \$250,000. This deal was promoted by Fred Swinney, of London, who will be general manager of the property, which is situated in Sonora, Mexico. These claims are 55 miles west of Carbo, 80 miles north-west of Hermosillo, and 30 miles from the Gulf of California. A little over 1,200 ft. of development work has been done on them.

The Arizona Copper Co. has made a concession to its concentrator men who walked out recently. Instead of a 50c. cut on the eight-hour day, it has been reduced to 25c., and does not include men who get \$2.50 or less per day. The offer has been accepted and all the mills are running full-force, eight-hour shifts. The new concentrator of the Arizona Copper Co., just completed, made a test run last week of all machinery except vanners and Wilfley tables. It is expected that the mill will be started about August 1. The operation of the new mill, No. 6, is under the direction of Wm. A. Moore, recently superintendent of concentrator No. 5 of the same company. Fred Marsden, who has been shift-boss for years at the Arizona Copper Co.'s concentrators in Clifton, is now foreman of No. 5. The Longfellow property, of the Arizona Copper Co. at Morenci, is undergoing improvement. Excavation is being made for a new hotel, the site of which is near, and on the same level as, the Humboldt mine. On the adjoining lot the company is preparing a free reading room for the use of its employees. An extensive sewerage system is being laid. This improvement, together with that already started by the Detroit Copper Co., will result in a much better sanitary condition in this community.—L. C. Miller, assistant forester, who recently came from Washington, D. C., for the purpose of establishing a forest nursery on Mt. Graham, this county, has men at work on an experimental station at Chlarson's sawmill. He has just returned from a visit to the Pinal reservation where he contemplates establishing another station in the near future.—The farmers and canal-owners of the Gila valley have united and engaged attorneys to bring suit to enjoin the three big companies of the Morenci-Clifton district who operate concentrators: namely the Arizona Copper Co., the Shannon Copper Co., and the Detroit Copper Mining Co., from running tailing into the river in future, and also to recover for damages already done. The tailing question is proving to be a serious one to the Gila valley agricultural section, and has been a source of much trouble between the farmers and the copper companies for a number of years. The companies have made consistent efforts to stop the large

flow of tailing into the river, and by constructing dams, have lessened it over 60 %, but still that does not satisfy the farmers.—The Detroit Copper Mining Co. has completed an addition to its ore-bins at the Copper Mountain mine, adding 40 % to their holding capacity.—Harry Hastings is chief engineer of the oil-burning engines of the Morenci Water Co. situated at Eagle Creek, seven miles west of Morenci.—The Detroit Copper Mining Co. has established a telephone system of its own with the central office in the office of the company's auditor.—The Ash Peak Mining Co. is putting in hoisting machinery and erecting new ore-bins near the Arizona and New Mexico railroad, over which it will ship ore to the Clifton smelters, the ore running as high as \$375 per ton in gold and silver. It now has one shaft down over 300 ft. and has lately installed a diamond-drill which is running full time.—The Holman-Keppler property in Mayflower district is showing up well, and the Copper Hill claims in that district now have a steady force at work.—On July 10 the Twin Buttes Mining Co. shipped 100 tons of ore to the El Paso smelter. It is the expectation to increase this shipment 100 tons every three months until it reaches 500 tons. Work on the railroad leading to this property is progressing rapidly. The track is now eight miles long.—A discovery of rich copper ore was made recently on claims owned by Frank West in the Stanley Butte mining district. Mr. West is superintendent for the Stanley Butte Mining Co. whose property is situated at the head of the Goodwin canyon. These claims were formerly owned by James Booken, and are six miles from the Belle group. The orebodies just discovered are said to be 40 ft. wide and assay 25 % copper.

Morenci, July 14.

MOHAVE COUNTY.

Gardner H. Smith and son, of Pasadena, are at the Gardner mines in the Wallapai mountain.—Bob Brannock has returned to Kingman from Secret Pass, where he is interested in promising mining properties. He reports the mines proving up well.—T. E. Ludlam, of Sea Isle City, N. J., is at the Mocking Bird mine in Weaver district, looking into the matter of putting in a pipe-line and mill. The mine, under the management of J. D. Jordan, has been developing into a promising gold property.—Work is progressing on the Boulevard mine of the Sheeptrail group, 15 miles north of the Gold Roads mine. The orebody is found to be large and of good grade. It was in this mine that the old company lost the vein. It is now yielding hundreds of tons of ore monthly. The company has put on another team and is preparing to start all the stamps at the mill. W. C. Howard is superintendent.—E. Riveroll, of Chloride, is getting the smelter in readiness to start as soon as coke is received. A carload of coke is at Kingman. If this small smelter will handle the ore of the Pinkham mine successfully it is probable that a large furnace will be put in.

PINAL COUNTY.

(Special Correspondence).—The Bryan group of mines at Florence, has commenced regular shipments of ore containing 15% copper to the Humboldt smelter in Yavapai county.—Henry Thompson, of Globe, accompanied by several mining men from Gila county, was in Superior district most of last week negotiating for bonds on a number of mining properties.—The Woodbury brothers have named their camp in the Rogers district, Woodbury Park. They have incorporated the Superstition Mining Co. to develop and operate a group of lead-silver claims situated in the Superstition mountains, 40 miles north of Florence. The properties to which they have acquired title have yielded a great deal of rich silver ore in the past.—Last week George B. Chittenden, general manager of the Saddle Mountain Mining Co., paid into the land-office at Phoenix, \$16,000 for 800 acres of coal land, covering the lower basin of Deer creek. Mr. Chittenden had previous to his purchase developed a bed of good coal, five feet thick. Tests proved this coal to be first-class fuel, as well as good coking coal. The Saddle Mountain Co. will install coke-ovens, as it is only 12 miles from this coal-bed to its smelter at Christmas. The grade for an electric railroad between the two points has been completed and the track and pole-line will quickly be placed. When this and the coke-ovens shall have been completed the Saddle Mountain Co. will double its furnace

capacity, as it has sufficient ore in sight to justify it.—W. G. Ham, of Florence, went to Goldfield district the past week to take down the old Bull Dog mill of 10 stamps. It will be removed to Ray, to be erected on the property of the Big Lead Co. to crush for concentrators.

Phoenix, July 14.

YAVAPAI COUNTY.

Within the past year the revival of the mining industry in that part of the Hassayampa mining district lying south of, and tributary to, Prescott has been noticeable and the shipments of ore from the different camps have been continuous.—South from Prescott the Cottonwood Copper Co., on Groom creek, is shipping ore. A small force is employed.—In this neighborhood arrangements are being made for resuming operations on the Ideal mine.—At the Senator adit, near Mt. Union, miners are sinking the Treadwell shaft to connect with the adit, and the driving of a drift on the Ten Spot vein is progressing.—On Mt. Union the Storm Cloud is being developed by the H. J. Beemer Co., and results are satisfactory. Ore of the average value of \$50 per ton in copper and gold is being mined in the adit, where the pay-streak shows an average width of three feet. This company is also sinking the shaft on the Ten Spot vein, rapid headway being made there, since the installation of the compressor and power-drills.—In the Slate Creek district there is a large amount of high-grade ore on the dumps of the Dunkirk mine, ready for shipment to the Humboldt smelter.—On the Davis vein men are driving the adit and sinking a double-compartment shaft to connect with it.—The Mt. Union Consolidated Mines Co. has a large force at work, and two miles east Harry Ames is developing a promising property from which high-grade ore is being extracted.—In Crook canyon the Juanita Mining Co. is driving two adits along a vein from which ore of good grade is being taken, and A. B. Spence is developing a gold-bearing vein.—Lute Wilson, whose claims are near Crook and Mt. Union, is taking out high-grade ore.—Near the Blue Dick, J. R. McDonald has a four-foot vein of \$20 ore in the adit on the Mark Twain mine, which is an extension of the Blue Dick. A number of prospectors and miners are sending enough rich ore to market to continue development of their prospects.

CALIFORNIA.

AMADOR COUNTY.

(Special Correspondence).—During the past few days there has been an unusual number of accidents in mines along the Mother Lode in this and neighboring counties, some of them fatal. Two men employed in the App mine, at Quartz, were caught in a cave, on Tuesday of last week, one of whom has since died from injuries sustained.—In the Argonaut mine, at Jackson, a few days ago a miner narrowly escaped death by a cave, in which he was seriously injured.—At the Gwin mine, in Calaveras county, on Friday of last week, a miner fell in a stope, and was seriously hurt, and at the Kennedy mine, near Jackson, S. Garbarino was injured by a cave on Friday. Monday, July 16, a miner was killed by falling down a shaft at the Eagle-Shawmut mine, near Chinese. This is a greater number of accidents, within a few days, than usually occurs along the Lode in a year.

Jackson, July 17.

CALAVERAS COUNTY.

It is reported that the Morgan mine, on Carson hill, five miles south of Angels, owned by the James G. Fair estate and Louis Irvine, will soon be re-opened after an idleness of many years. It has been shut down through litigation. The same parties, it is said, will re-open the Crystal mine, at Angels, near the Lightner.

EL DORADO COUNTY.

(Special Correspondence).—White and Davis, six miles from Shingle springs are taking out some good ore and crushing it in their two-stamp mill.—The Jasper Mining Co. will soon have its three-stamp mill completed.—Grainger & Wallace shipped 11 lb. of gold in their last clean-up at the Davidson ranch drift mine.—The Pyramid Mining Co. will continue the shaft from the 500 to the 1,000-ft. level. The vein is from 10 to 12 ft. thick. The 15-stamp mill will be replaced by one of 40 stamps.—The Union mine is operating with a small force.—Seymour Hill, at

the German mine, five miles from El Dorado, is doing development work.

El Dorado, July 16.

William Cole and son, who took several thousand dollars a few days ago in the Golden State mine near Georgie Slide, have sublet their lease to Clifford Cheek. W. J. Davey is working the interest of G. Smeder, in the mine.—C. Cobb and R. Morris have placed a steel whim on the Railroad Hill mine, three miles from Greenwood.—The California Jack mine, three miles south of Georgetown, has been bonded by the company now working the Alpine. It will develop the mine, and the work of reconstructing the old mill has commenced.

INYO COUNTY.

The scene of one of the latest stampedes is to the Wild Rose district, also known as Emigrant Springs, situated in this county about 16 miles from the line of Nevada, on the west side of Death valley and on the east slope of the Panamint range. In the early history of that district ore was shipped from Panamint to San Pedro, via Los Angeles, and thence to San Francisco for treatment. The rush to the Wild Rose district is not very big as yet, owing to the intense heat of that region during the summer months, but with the coming of fall all who have not already made fortunes in southern Nevada camps, and a few who have, may be expected to visit the new field of excitement.

LOS ANGELES COUNTY.

The Union Oil Co., of Los Angeles, announces that the company has signed a contract with parties in Chile for 10,000,000 bbl. oil to be delivered within a period of 10 years at the port of Iquique, in the State of Tarapaca. About a dozen companies in the nitrate field will use the oil for fuel, and railroad officials in that country have announced their intention of putting oil-burners on the engines of their roads. The company will use foreign tank-steamers to transport the oil, the delivery of which will commence this fall. The Union Oil Co. also announces that it will begin the shipment of its product to the Isthmus of Panama within the next 60 days. The oil will be stored in four tanks having a capacity of 200,000 bbl., at each end of the Panama railroad.

MARIPOSA COUNTY.

On Cox creek half a mile below Corbett's ranchhouse Smith & Jones are building a quartz mill. The vein they are working is near at hand. A great deal of pocket mining is being done in the country lying between Bear Mountain ridge and Hornitos. This part of the foothill country has been successfully searched for pockets for many years.

MODOC COUNTY.

Mining development has put new life into Cedarville and Fort Bidwell. Cedarville is building a \$3,000 town-hall, the Surprise Valley bank is breaking ground for a \$10,000 block, and a power company is constructing a line to Pine Creek, a distance of 17 miles. At Fort Bidwell a large hotel, a restaurant, and other buildings are in course of construction, and the town will soon be equipped with electric light. John Patterson is figuring on establishing automobile service in the valley. The prospects recently opened in the neighborhood of Fort Bidwell promise to develop some paying mines. The district has been retarded in its development by its isolation from the outside world, and by the expense of transportation.

NEVADA COUNTY.

The Olympus Mining Co. has been incorporated by Cyrus Bradley and F. L. Kershaw, of Spokane, and H. Reiter, of Grass Valley. They own and will work property in this county.

PLACER COUNTY.

The Home Ticket gravel mine at Last Chance is working from 15 to 20 men and is said to pay \$8 to the man. Frank Tillotson is superintendent. The mine is owned by Alfred Dixon and others. There are two other mines in the Last Chance district which are good claims—the El Dorado, owned by D. M. Ray, with Millard Hyland as superintendent, and the Startown, with Will Davis as superintendent. The Blueeyes is also being worked.—The Three Stars, west of Auburn, has been running during the past month on

some of the best ore ever seen in the mine.—It is reported that the tributers have ceased work on the Turkey Hill, near Michigan Bluff.—As soon as the snow melts, there will be much prospecting done in the Canada Hill district.—The Barton mine, near Westville, is to be re-opened.

RIVERSIDE COUNTY.

The Good Hope mine, near Perris, has been sold by Hook Bros. to the newly organized Shaftrock Mining Co., which proposes to re-open and equip the property on a modern basis. The Good Hope has produced many thousands of dollars under adverse conditions, and with inadequate milling facilities.

SACRAMENTO COUNTY.

(Special Correspondence).—Keefe & McDermott at the Spring Hill gravel mine are working five or six men owing to scarcity of water.—At the Blue Ravine drift mine, under the management of A. C. Kern, the force of 40 men will be increased. The men are working eight-hour shifts, underground on contract. The mine is well equipped and promises to be a steady producer.—The Folsom Development Co., R. G. Hanford, manager, is operating five dredges. The men work eight-hour shifts, three men to a shift. The dredges run continuously, day and night. About 125 men are employed, the greater part of whom are working on repairs. The plant is equipped with a first-class, modern machine-shop. The entire plant is up to date in every detail.

Folsom, July 16.

TRINITY COUNTY.

The Fairview mine, near Weaverville, which has been closed down since last spring, is to be re-opened. Chas. Doebler is superintendent.—The owners of the Bonanza King mine, ten miles from Trinity Center, find difficulty in equipping it with a 20-stamp mill. The altitude is 7,000 ft. and the mine is reached by a trail. A wagon-road five miles long is nearly finished at a cost of \$25,000, there being 200 men employed on the road, at the sawmill, on mill-construction, and in building an electric power plant with a capacity of 600 h.p. There is a large body of ore on the claim.

COLORADO.

GILPIN COUNTY.

W. C. Cutler, of the Mountain Monarch Mining Co., has put men at work on the Chieftain and Seth Thomas veins, in Gambell gulch. The main adit is 700 ft. The company—in which Centerville, Iowa, people are largely interested—intends to put new concentrating tables in its mill.—The Copper Jim group is situated in South Boulder canyon, above Boulder Park, and is operated by the Copper Jim Mining Co. under the management of James A. McCracken. This company has started an adit and will prospect the property. A new cabin and blacksmith-shop are to be built at the adit.—James A. Gilmour, of Central City, will resume operations on his Daisy Extension group on Perigo hill, consisting of five patented and one unpatented claim. The main shaft is down 130 ft. and the owner intends sinking it to the level of the Perigo adit which will give 400 ft. more depth and drain the property. Drifts will also be run at a depth of 130 ft. east of the shaft. It is the intention of Mr. Gilmour to remove the Daisy mill from Gambell gulch to a site near the mine, to save the cost of hauling ore and with the shaft down to the adit-level of the Perigo property there would be plenty of water to use for milling purposes. There is a first-class plant and a good building on this property.—The Wire-Gold Mining & Milling Co. has resumed sinking on its new shaft up Black canyon, its present depth being 35 ft. Free gold has been taken out of the surface workings and the company (mostly Nebraskans) will develop the property for shipping.—Work has been resumed on the Gold Dollar group on the south side of South Boulder creek by Central City owners. Development is by adit, which is in 400 ft.—Three shifts are at work at the Black Hills and Denver main adit in Boulder Park, and Superintendent Van Fleet reports that they are making eight feet per day. A three-foot vein has been opened up; it carries \$10 per ton gold, silver and copper.—A compressor has been delivered to the Golden Sun adit and the new 100-h.p. boiler has been installed and the foundation for the

compressor is nearly finished. The main adit is in 550 ft. and the company intends to open up all of its property through it, as well as to extend it on the Perigo and Tip Top mountain to cut the Perigo, Gold Dirt, Mountain Chief and other veins which have been big producers. E. T. Butler is in charge of the operations.—Two cars of tailing from the Perigo mill were shipped to the Argo smelter from Rollinsville depot last week.—A number of the mines in the North Beaver creek section are taking out tungsten ore and several shipments are being taken out for Denver buyers.

IDAHO.

CUSTER COUNTY.

W. H. Plummer, of Spokane, has purchased for \$100,000 a group of 27 claims in the Big Copper basin, for a syndicate of New York and Boston men. The claims are crossed by two well-defined veins, from which 61 assays have given an average of \$33 per ton copper, with a little gold and silver.

MONTANA.

FLATHEAD COUNTY.

E. M. Heyborn, George H. Walters and C. W. Moegling, of Spokane, have acquired the property of the Shaughnessy Lead & Silver Mining Co., near Libby. A new company, a close corporation, has been formed and will work the property, for which \$24,500 was paid.

NEVADA.

Hot weather is retarding operations in the Nevada camps. In some of these, surface operations have had to be practically discontinued, men being unable to work in the open. Where operations are carried on underground, as in the more developed mines of Goldfield and Bullfrog, work is proceeding without material interruption; but at Fairview and several of the newer camps it is difficult to continue work on or near the surface. Construction work on the railroads is also being retarded somewhat; and it is reported that on the so-called Borax Smith line, being built to Bullfrog northward from Ludlow on the Santa Fe, in California, large numbers of men deserted, being unable to endure the stifling heat. In spite of this handicap Goldfield, and Bullfrog in particular, are advancing steadily, an unusual number of strikes having recently been reported in the first-named camp.

DOUGLAS COUNTY.

The Kennedy & Pitt mine, at Buckskin, has been closed down, owing to the increase in wages established by the miners who recently organized a local branch of the Western Federation of Miners. From \$4 the scale has been increased to \$4.50 and \$5 for contract work. The camp has always had a \$4 scale, but no distinction was made between various grades of labor. When the scale went into effect the Kennedy & Pitt mine was closed. Several other operators complained, but they are proceeding with development.

LINCOLN COUNTY.

(Special Correspondence).—On the heels of Charles M. Schwab's man, McKnight, who secured more than one good mine and a number of promising prospects for his principal, have come J. T. Wisner, of New York, H. B. Adsit, of Denver, A. T. Jergins, H. H. McCord, H. Shannon and J. Donnan Reaves, of Los Angeles, who were surprised to find so many others on the ground before them inspecting properties and making deals. There is no indication of a dull season in Searchlight this year. Mr. Wisner is inspecting the Philadelphia group of five claims in the Nob Hill district, and the Searchlight Treasurer-Gold, which are two of the properties in which his firm is interested. He is accompanied by F. F. Corliss and E. F. Flanagan, of Massachusetts, who are also interested in Searchlight properties. The shaft being sunk on the Treasurer-Gold has encountered a lode six feet wide, samples from which assay from \$4 to \$146 per ton. An 8-h.p. hoist has been used to attain the present depth of 100 ft. and it is stated that a larger one has been ordered. Improved facilities for preparing the ore of the Duplex mine for shipment to the Needles smelter have been completed. The present output amounting to about a carload per week will be increased when better transportation is available by the completion of the Barnwell & Searchlight railroad. An order for 24 miles of 50-lb. steel rail has

been placed for the Searchlight railroad. Prospecting on the Sunny Jim group of three claims this week disclosed a 30-ft. vein of porphyry and quartz with a four-foot streak averaging \$8 per ton. The Colorado Mining & Milling Co., represented here by its vice-president and manager, H. B. Adsit, has purchased a 25-h.p. gasoline engine and a 50-h.p. hoist and commenced sinking a 200-foot double-compartment shaft, 5½ by 11½ ft. in the clear, on the New Year claim. The company has also ordered a pump of 120-gal. per min. capacity, and it is expected that the new equipment will be on the ground about September 1, when the 200-ft. shaft will probably be completed.—The Cyrus Noble Extension, having reached the 100-ft. level, will now open a level by cross-cutting and driving on the vein.—The Searchlight Electric Light plant is nearing completion. Ore reported to run about 40 % lead and 30 oz. silver has been struck on the Annette property. The lead ore is galena.—In El Dorado Canyon district it is reported that the management of the Mocking Bird group has ordered machinery to develop at greater depth a vein rich in gold. A gasoline engine has been ordered for the El Dorado; also a blower. The shaft is now 150 ft. deep and the present equipment is inadequate for further sinking.

Searchlight, July 14.

NYE COUNTY.

(Special Correspondence).—The warm weather seems to have stimulated mining operations in the Manhattan district, for development is being carried on with more vigor than ever and some new strikes have been reported. Several workings are now nearing the 200-ft. level, in ore of better grade than found near the surface. The double-compartment shaft on the Manhattan Con. is down 125-ft. and with the large pump to handle the water there will be no trouble in carrying on the work to greater depth. This property has the distinction of having the first high-grade ore in the camp. The trend of the orebody of the Manhattan Con. is toward the property of the Manhattan Mother Lode Mining Co., to the southeast, and that company is prospecting for the shoot by means of an adit. The Consolidated Extension, to the northwest of the Consolidated, has the orebody in its adit, and is now blocking out the ore. A mill will be erected on the Extension property.—The shafts on the Union No. 9 claim, of the Manhattan-Dexter and the Little Gray, are now down nearly 200 ft., both on the same vein of milling ore, with occasional streaks of high-grade ore, which is being shipped. Contracts have been closed for a 25-stamp mill, which will be erected at Central, two miles west of Manhattan. The site of this new mill is advantageous for the Manhattan Nevada Gold Mines Co., which is driving an adit on the Georgey group at Central. Ore has been opened up at the various places on this property.—The lessees on the Pay Ore claim of the Paymaster Mining Co. are sacking ore. Some specimen stuff has been taken from the Sullivan lease on the Pay Ore claim.—The Sentinel claim, which, it is understood, will be taken into the Manhattan Combination Co., still attracts attention. The ore piled on the dump will be shipped to the smelters at Salt Lake City.—The shaft on the Mustang is down 175 ft. and several veins of milling ore have been cut. It is the intention to sink and cross-cut to the various veins. A force is at work on the Broncho Mining Co.'s property adjoining the Mustang, between that property and the Manhattan Express, which is also the scene of activity. A large vein, which can be traced through the Mustang, Broncho and Express, has been opened up on the Buyo claim of the Mustang Co. This is an entirely new vein, and much activity is being shown in its rapid development.—Word comes from the Buffalo Mining Co. at East Manhattan that a mill will soon be in operation at that point. The Manhattan Mammoth is in good ore at 240 ft. in its adit, and the Consolidated Manhattan is in good milling ore at 166 feet.

Manhattan, July 14.

Two prospectors, Clark and Johnson, are lost in Death Valley and are thought to have perished not far from Emigrant Springs. They were last seen July 8. Searching parties are looking for the missing men. The prospectors started from their camp near Emigrant Springs, carrying only one canteen of water, to go to their prospect a short

distance away. They have not been seen since. It is supposed that they lost their bearings and were overcome by the heat.

WYOMING.

BIG HORN COUNTY.

The 150 laborers on the Corbett tunnel of the Government irrigation dam at Cody who struck a few days ago and took possession of the camp and defied the authorities, were promptly shipped East. Company E, Wyoming National Guard, and a deputy sheriff with 30 deputies, swooped down upon the camp of rioters, who surrendered without firing a shot. They were paid off by the reclamation officer, marched to Cody and placed aboard a train. The State troops patrolled the town all night and until the rioters left.

The 500 workmen who had been intimidated by the strikers returned to work the following morning.

MEXICO.

GUANAJUATO.

In a recent interview in Mexico City concerning the Guanajuato mining district, Dwight Furness said:

A year ago I predicted that the monthly output from the Guanajuato mining district would be \$1,000,000, and from present indications I believe my prediction will come true before the end of the year. An average of \$250,000 per month is being expended now in Guanajuato in adding new machinery and developing the mines. The work there is past the bonanza stage and the owners are not looking for rich strikes. They have settled down to working the mines on a sound business basis, and as a result are extracting valuable ore. The Guanajuato Reduction & Mines Co. is working the dumps and its success in this direction is even better than predicted. The company will begin soon to work the mines, and will have even better success. The most promising mine at present is the Pinguico, which has shown up wonderfully rich. As soon as arrangements for handling the ore, shipping, etc., are arranged, it will be yielding \$100,000 per month. The thing most needed at present, however, is a railroad. We have completed plans and have them before the Government now for approval for a line from Salamanca to Guanajuato. This line will connect with the National lines at Salamanca, and when completed will greatly help Guanajuato. Capital in the United States is being interested in this line and we expect to begin work at the close of the rainy season. As most of the route is favorable the road will be completed in a year. The Central also is planning the extension of the line from Marfil. This need of a railroad is what is holding back the development of the mines at present. The yards at Marfil are now filled with cars of mining machinery which cannot be handled fast enough with the present limited railroad facilities. In addition hundreds of cars are held at Silao until those at Marfil are gotten out of the way. Loads of machinery are being shipped into Guanajuato as fast as possible, but the work will be retarded until our new line is constructed. With conditions as they are at present, however, the future of Guanajuato looks very favorable indeed. The entire district is in a prosperous condition.

SONORA.

The 50-stamp mill of the Llanos de Oro Co. was started last week. The Llanos de Oro is a placer property in which the gold is found at depth in the old bed of a river which has since changed its course. The formation is strictly placer, though it has been reached by means of shafts and drifts. The dirt hoisted is cemented and requires crushing to liberate the gold. The initial tests gave good results. It is understood that if the stamp-mill proves satisfactory, it will be doubled. The San Juan Bautista Mining Co. in the Moctezuma mining district has made a 20-ton sample run at the Cumpas smelter on ore which netted a little over \$3,000. The ore was not sorted.

AFRICA.

TRANSVAAL.

For some time past several prominent mining men in Johannesburg have been acquiring ground between the Black Reef and the Klipriversberg series, and it is reported that an important discovery has been made, and that a new reef has been traced from Zuurbekom, adjoining Gembok-

fontein of the Western Rand Estates on the west, to Rooikop on the east, where the Orion mine is situated, to Finaalspan. A reef has been opened up underlying the Black Reef series and a certain amount of exploration has been done on this body with good results. A shaft has been sunk to a depth of 170 ft. and assays at this depth are encouraging. The horizon of this new discovery is placed between the Black Reef and the beds of the Steyn Estate series, and it is contended that the discovery throws an interesting light on the strikes made by the Western Rand Estates on Gembokfontein and adjoining properties. In addition to the discovery mentioned, there has been a good deal of locating recently in the vicinity of the Van Ryn mine. Licenses have been taken out for no less than 1,500 claims. While it does not seem likely that the Van Ryn people would allow any reef close to their mine to remain unprotected, it is only recently that a new discovery was made in the underground workings of the company, and a considerable tonnage of ore unknown to exist a few months ago has been added to the mine.

CANADA.

BRITISH COLUMBIA.

The Tyee Copper Co., Ltd., of Duncans Station, Vancouver Island, reports smelter returns for June as follows: Smelter ran 15 days and treated 3,123 tons of Tyee ore, giving a return, after a deduction of freight and refining charges, of \$36,630.

(Special Correspondence).—Adrian G. Hanauer, of Spokane, has received word that the aerial tramway, the saw-mill and the pipe-line are practically completed on the property of the Bear Hydraulic Mining Co. at Bakerville, B. C., in Cariboo district. Seventeen Chinamen and five white men are employed. The company owns 6,780 ft. along both sides of the channels of Cunningham and Pass creeks. The pay-gravel is 400 ft. deep. This holding of the company is said to comprise the largest area of unworked gold-bearing gravel in Cariboo district. B. Laseke and Joseph Wendelle are in charge of the work.—The Five Metals Mining Co. will build a smelter on the company's property, seven miles from the Five Metals landing on Kootenay lake. The property is owned chiefly by Spokane people.—George Turner says the Sullivan mine, 20 miles north of Cranbrooke, will soon pay off the remaining \$20,000 of the \$125,000 advanced to the company by Charles Sweeney. He says that the company is smelting 100 tons of ore per day.—A. B. Campbell, of Spokane, has taken a bond on a group of quartz claims in Alaska, and has sent experts to examine the property. The claims are on Falls creek, a stream 22 miles from the Seward, Alaska & Central Railway.

Spokane, July 14.

The ore output of the mines of the Boundary for the month of June, 1906, was 102,589 tons. The ore output and smelter treatment of the Boundary mines for the week ending July 14 was as follows: To Granby smelter from Granby mines, 15,640 tons; from Emma, 99 tons; to British Columbia Copper Co.'s smelter from Mother Lode, 1,024 tons; to Dominion Copper Co.'s smelter from Brooklyn-Stemwinder, 3,531 tons; from Rawhide, 330 tons; from Sunset, 825 tons; from Mountain Rose, 40 tons; to Nelson smelter from Emma, 77 tons. Total shipments for the week, 21,566 tons. Total for the year to date, 661,889 tons. Boundary smelters treated this week: Granby smelter, 16,350 tons; Dominion Copper Co.'s smelter, 4,726 tons. Total for week, 21,076 tons. Total for year to date, 667,249 tons.—A strike of rich ore is reported on the Strathmore mine, at Greenwood, at the 100-ft. level. James Donohue, of Chicago, who is interested in the property, says electrical machinery has been ordered.—A. J. McMillan, managing director of Le Roi mine at Rossland, reports that the mine shaft is to be deepened from the 300 to the 1,700-ft. level. Explorations have proceeded by means of a winze from the 1,300 to the 1,700-ft. level. As some large shoots of ore of a high grade were found below the 1,300-ft. level it has been decided to sink the shaft. It is a five-compartment shaft and the extension of it down to the 1,700-ft. level will cost a large sum.—Following are the shipments for the week: Centre Star, 2,076 tons; Le Roi, 2,820; Le Roi No. 2, 570 tons. Total for the week, 5,466 tons, and for the year, 172,831 tons. The reports of ore at the Trail smelter for the week were 5,681 tons.

Personals.

HENNEN JENNINGS is expected in San Francisco.

CHESTER W. PURINGTON has returned to Denver from Boston.

L. D. RICKETTS has returned to Bisbee from a trip abroad.

R. H. GOODWIN has returned to England from British Guiana.

C. W. GEDDES and C. W. ABBOTT are at Urique, Chihuahua.

JOHN W. HUGHES has returned to Fairbanks, Alaska, from Los Angeles.

GEORGE KISLINGBURY, of Los Angeles, is examining mines in New Mexico.

W. P. MARTIN is mine foreman at the Gold Flat mine, near Grass Valley, Cal.

EMIL HUERTER is metallurgist for the new Central Zinc Company, in England.

LOUIS D. RICKETTS has returned to Globe, Arizona, from a flying trip to Europe.

JOHN ROSS, JR., has returned to Sutter Creek, Cal., from a trip to mines in Oregon.

JAS. W. ABBOTT is visiting San Francisco, on his way from Denver to Los Angeles.

CHAS. A. SHORT of Goldsprings, Utah, is manager for the Jenny Gold Mining Company.

E. B. QUIGLEY is superintendent of the Barton mine, near Michigan Bluff, California.

GEORGE A. BAIRD, of Sharon, Pa., president of the Western Exploration Co., is at Salt Lake.

A. R. MILES is superintendent for the Blue Flag Gold Mining Co. at Breckenridge, Colorado.

W. H. PAUL, of Denver, is now in charge of mines in Las Plomos district, Chihuahua, Mexico.

W. M. TURNER is now foreman of the Green Mountain Consolidated mill, at Silverton, Colorado.

MICHAEL F. BURKE and some Boston friends are inspecting mines at Breckenridge, Colorado.

D. A. CONNOLLY, on his return from Mexico, has opened an office at 318 Laughlin Bldg., Los Angeles.

H. M. RIDGE has been appointed general manager for the Central Zinc Company, on the Tees, England.

CORY C. BRAYTON has been appointed manager of the Dairy Farm mine, in Butte county, California.

W. F. COLLINS is manager of the Holy Terror-Egyptian Consolidated mines, at Keystone, South Dakota.

O. N. BROWN, of Deadwood, is general manager of the Iowa Mining Co., at Central City, South Dakota.

L. MAURICE COCKERELL has resigned as manager of the Mesquite Gold Mines, Ltd., in Zacatecas, Mexico.

T. H. MERRITT is manager of the Comanche Mining & Smelting Company, near Silver City, New Mexico.

HARRY MCCREARY, formerly of Indiana, Pa., and now exploring in Nevada, visited San Francisco this week.

B. A. LANGRIDGE, of Boulder, has been appointed State Geologist of Colorado, in succession to JOHN W. FINCH.

J. D. SHILLING, of Michigan, has been appointed general manager of the mines of the Utah Copper Co., at Bingham.

GEORGE M. STOCKINGS has been appointed manager to the Carolina Development Syndicate, in the eastern Transvaal.

STANLEY N. GRAHAM, formerly of Guanajuato, has been appointed superintendent of El Favor mines, in Jalisco, Mexico.

CHARLES S. PALMER has resigned as associate editor of *The Engineering and Mining Journal*. He is on a holiday trip in Maine.

DUNCAN MACVICHIE is now managing director of the Bingham Consolidated Copper Co. and H. L. CHARLES is general manager.

P. J. DONAHUE, of Salt Lake City, is consulting engineer for the Standard Copper Co., recently organized to operate at Bingham, Utah.

JOHN PETERSON, formerly of the Winona mine, is now in charge of underground work for the Hancock Consolidated Co., at Hancock, Michigan.

JOHN V. BOHN, lately at Butte, has been appointed superintendent of the Green Mountain & Lone Pine mines, in Mariposa county, California.

CHAS. W. CLAWSON, superintendent of the Copper Queen mines, has returned to Bisbee from an inspection of copper mining methods in the Lake Superior region.

A. A. COLE, lately with the War Eagle and Centre Star mines, at Rossland B. C., has been appointed a mining engineer to the Temiskaming & Northern Ontario Railway Commission.

Obituary.

ALBERT BEIT died in London on July 16. He was associated with Cecil Rhodes in the development of South Africa, and became one of the wealthiest men in Europe through successful operations in connection with the De Beers diamond mines at Kimberley and the gold mines of the Rand. He was a German Jew, born at Hamburg in 1853. A man of large ideas, personal generosity and kind disposition, he was much respected in the financial world of London and Berlin. His immense holdings in South Africa will be administered by the firm of Wernher, Beit & Co., of which Sir Julius Wernher is the senior and surviving partner.

STANLEY H. PEARCE died at Magdalena, in Sonora, Mexico, on July 10. He had been ill but a short time, the cause being erysipelas. He leaves a wife and two children. Stanley Pearce was one of the four sons of Richard Pearce, of Denver, and his sudden death will be keenly felt among a large circle of friends. He was only about 38 years old. A graduate from the Sheffield Scientific School of Yale University, he obtained his first experience at Butte, where he was employed by the Colorado Mining & Smelting Co., under Chas. W. Goodale. During the Klondike excitement, he equipped an expedition and went to the Yukon. Subsequently he engaged in copper mining at Magdalena, near Nogales.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

THE first hoisting by steam on the Comstock Lode was done in the Ophir incline by wrapping a rope attached to a bucket around the shaft of the pumping engine.

THE WHEELER PAN was first patented December 8, 1863. The Varney pan, with its mechanical stirrers, was decided by the court to be an infringement on Wheeler's patent.

THE value of the mill gold produced by amalgamation on the Rand is about \$18.40 per oz. That of the Homestake about \$17. Placer gold is always finer than mill gold from the same original sources.

'FLOURING' of mercury is the minute subdivision of it by mechanical causes and 'sickening' is the rendering of such a condition permanent by the intervention of a coating of foreign substance, which prevents the coalescing of the globules.

THE fewer the appliances required to extract the metal out of the ore the better; a marksman is not considered a good shot who misses with his first barrel. Don't overlook the vanners because you have got a canvas plant for your tailing.

WHERE a mine produces some high-grade ore which occurs so disseminated as to make sorting necessary, it is good business to put in rolls, trommels, and jigs, producing a concentrate that can be shipped, the silicious gangue being milled at the mine.

THE average red clay brick has a modulus of rupture of 500 lb. per sq. in., and crushing resistance up to 5,000 lb. per sq. in. The best bricks exceed these figures about 20%. Pale red bricks are not usually so strong as those of full red color.

LINARITE is a basic sulphate of lead and copper, occurring in deep-blue crystals. It may be easily distinguished from azurite (blue copper carbonate) by the ready effervescence of the azurite in nitric acid. Linarite does not effervesce in acids.

GRAPHITE has been successfully employed as a lubricant in gasoline engine cylinders, and it may possibly be suitable for compressors, though we have no data on the latter. The graphite could be fed to the cylinder through the valves on the intake stroke.

ANY form of protection from lightning in electric wiring is without value unless the ground connection is carefully made. It is not sufficient to connect the ground leads to a rail or even to a pipe driven into earth, but a reliable ground connection must be secured.

'METALLICS' is the term applied to those bits of ductile metal (usually native gold, silver, or one of the malleable sulphides), which do not pass through the sieve of the assayer in that process of final pulverization which the pulp undergoes before being weighed for the crucible.

A WEST AUSTRALIAN authority describes 'strike' and 'lock-out' as follows: "A strike may be defined as a refusal by the workers to continue to work for their employer unless he will give them more wages or better conditions of labor. A lock-out is the converse of a strike. It is the refusal of an employer to allow his workmen to work unless they will accept his rate of wages, or the conditions of labor he imposes. In neither

case is the employment finally determined, the intention of the workmen in the one case, and the employer in the other, being that the employment shall be continued if a satisfactory settlement of the matter in dispute can be arrived at."

THE first stamp-milling in the United States was done in Georgia, but the modern stamp-mill had its origin in California. The Georgia methods of milling were based on the older practice of Hungary. Hungary borrowed from Egypt.

SANDSTONE occasionally carries gold, but where this is the case the probability is that the gold is fragmental and was deposited contemporaneously with the material now forming the sandstone. Rarely it is due to subsequent infiltration along cracks.

MERCURY solidifies at -40 degrees C., and boils at 360 degrees C. It emits vapor at 15 degrees C., and perhaps at even lower temperatures. It is the worst conductor of heat of all the metals, its conductivity being only 5.33, that of silver being taken at 100.

TESTS have been made recently on the corrosion of boiler-tubes by forcing air through tubes made wet with distilled water. In 16 weeks the loss in weight was 0.315 gram per square inch. When the water was made alkaline, the loss in the same time was reduced to only 0.0997 gram. It appears that if the water in a boiler is made slightly alkaline the corrosion of tubes may be materially reduced.

CAVING of ground in mines is usually accompanied by concussion of the air, which is destructive in its effects in proportion to the magnitude of the cave. A cave in the Imperial mine, on the Comstock, occurring in March, 1863, caused rocks to be blown up the shaft more than 300 ft., the fragments striking the roof of the hoist-building which covered the shaft. This was due wholly to the rapid expulsion of air from the workings by the collapse of ground. Broken rock occupies about 50% more space than when in place, and the sudden caving of a large mass thus displaces a great volume of air.

TURQUOISE occurs in eruptive rocks, usually trachyte or rhyolite. It is a hydrous phosphate of aluminum, colored by copper salts. Its hardness is 6—a little less than that of quartz—which serves to distinguish it from chrysocolla, the copper silicate, the hardness of which varies from two to four. It is soluble in hydrochloric acid; on addition of ammonia there is a pronounced blue coloration, due to the presence of copper. Natural turquoise is often treated to give it the desired blue color. Some varieties possessing a fine color when first excavated, fade on exposure to pale greenish-blue, but turquoise of this sort is not in demand. The mineral occurs in small irregular bunches and in veinlets in the lava, which usually is brecciated.

It would be dangerous to attempt to operate a hoisting engine in lowering a bucket, skip, or cage, depending wholly on the air compressed in the engine-cylinder by the reciprocal movement of the piston to act as a brake without any other means of control. Engines are made having auxiliary cylinders set tandem with the engine-cylinders and connected with the air-receiver of a compressor, but this style of brake arrangement has not become popular as yet. The best type of hoisting-engine control is the post-brake, though many believe the band-brake and the end-friction brake are equally safe. Some large hoisting-engines have steam-brakes which are usually set unless the steam is shut off. These brakes operate automatically.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

A Mining Method Wanted.

The Editor:

Sir—I have read with interest the problem submitted by 'New Superintendent' in your issue of May 19, namely, "The cheapest and best method of extracting all the ore from a 50-ft. ledge, with a dip of 23 degrees." I cannot understand how so flat a ledge could be worked by the draw-stope system. I agree with the 'Prospector' in sinking a shaft from the surface and connecting it with the tunnel already driven below. I herewith submit my solution to the problem.

Sink an incline shaft from the surface in the foot-wall and about 30 ft. under the orebody, connecting it with the tunnel-level. While sinking the shaft, commence taking out the ore on the tunnel-level, on one or both sides of the cross-cut, from foot to hanging wall, carrying

letting down cribbing and waste. Run a drift from every station, parallel to the orebody in the foot-wall, and connect by a raise with the orebody, in order to form chutes for the upper foot-wall section of stopes, using the waste for filling the stopes below. When the stope reaches the height of 100 ft. or the cross-cut, timber on top of filling for another level. Pockets should be cut under each station and ore conveyed to the surface or down to the tunnel-level, as desired. The entire orebody can be worked in this manner at a small cost, the writer having had experience in mines where \$2.50 per ton ore was made to pay when worked by this system.

R. H. SUTTON.

Enterprise, Cal., June 30, 1906.

Elevator Machinery.

The Editor:

Sir—We are in receipt of a letter from Mr. F. Lynwood Garrison of Philadelphia concerning one of our elevators used at Carthage, Mo., in what is termed the Yellow Dog mine. This letter is in response to our letter forwarded

the breast of ore about 12 ft. high. As fast as the muckers clean out the broken rock, the whole space from hanging to foot-wall should be timbered with square sets, having 8-ft. posts. Cover the sets with 6-in. poles or 4 by 12-in. planks. Run the car-track on the foot-wall side of the stope, with turntables every 20 ft. for the tracks that go to the chutes on the hanging-wall side of the stope. Chutes should be put in every 20 ft., three in line from hanging to foot-wall. When the timbering is completed commence stoping on top of the sets, at each end of the stope, taking a stope about 10 ft. high from wall to wall; the machine-men will stand on the broken rock. When sufficient rock is broken so that shovelers will not interfere with the machine, commence shoveling rock into chutes. When about 50 ft. of stope is cleared of broken rock, filling should be introduced. First line chutes and manways with 10-in. cribbing or shaft-sets. The chutes, not less than four feet in the clear, should be carried up to about five feet from the back of stope and at an angle of 40° toward the foot-wall. Start cross-cuts in hanging and foot-wall to get waste for filling, the waste being conveyed in wheel-barrows to stope. As the work progresses, other cross-cuts should be started at convenient places. The entire orebody can be mined at one operation, or in sections. When the shaft is connected with the tunnel-level and stations cut every 100 ft., start a cross-cut at the first station above the tunnel-level and cut the orebody through to the hanging wall. Connect with the stope below by a raise, for ventilation, and also for

to him through you. Your paper was one of the first to speak of this system of elevating ores, and in an editorial on December 23, 1905, you spoke particularly about this system. The writer fully believes that where there is an incline to the shaft, ore can be successfully handled much cheaper by using a continuous-elevator system than by any other method. A continual flow of material is much better than by any other method if it can be practically done.

The operation of our elevator is as follows: The ore is dumped from regulation cars into a receiving separator at the bottom, and is automatically fed into the elevator and elevated to the top, a distance of 300 ft., at a cost of 1.8c. per ton. In estimating this total cost we have figured on a depreciation of 20% in machinery, and the usual depreciation is figured at only 10% in roller-chain, and this drop-forged chain is much more durable than roller-chain. Therefore we believe that we have been liberal in allowing the depreciation. We have also figured the cost of two men, one at the bottom of the elevator and one at the top. This is really not required, although we have included it in estimating the cost. We have included also the cost of fuel and interest on investment.

We do not know the exact cost of elevating ore a distance of 300 ft. at the rate of 50 tons per hour by the ordinary method. If you can give us this information direct or through your paper we should be very glad to have you do so. But our opinion is that a cost of less than 2c. per ton, including cost of motive power, is extremely low.

This cannot be considered an experiment, for the reason that the Underwriters Land Co. has just given us an order for a duplicate elevator, and the company is extremely careful and a shrewd buyer.

C. O. BARTLETT.

Cleveland, July 5, 1906.

[We shall be glad to publish figures or criticisms from others on this subject.—Editor.]

Mining Method Wanted.

The Editor:

Sir—The proposition put before your readers by 'New Superintendent' is extremely interesting to practical mining men, and it is to be regretted that more information regarding approximate average value of the ore per ton is not given. Wages, it must be assumed, are about the same as paid elsewhere through the southern part of the State of California; timber, it is said, is available, though its use is undesirable on account of the low grade of the ore. It does not state, however, whether the latter is gold, copper, or lead, etc. Another important consideration that is omitted is whether the reduction works, if any, are above or below the adit level or in other words whether it is necessary to raise the ore above that level on delivery at 'pit's mouth'; presumably not. Let us then, for the sake of a clearer discussion, assume that the ore is worth say, \$3 at pit's mouth and that it is not necessary to raise it above the level of the adit on reaching surface.

In my opinion the Prospector's method of *stoping* the rock is good, but the general scheme has several weak points, as follows: It may be necessary to sink the incline, or as I would suggest, *raise* from the intersection of the adit and the vein, to the surface, yet this work should be done in the vein and not below it and if the ore will produce \$3 per ton as assumed, the operator would have over \$5,000 in hand for future work—a weighty consideration; nor should this method be disadvantageous in any way. Instead of running the bottom of the stope into the barren foot-wall as shown in the sketch accompanying Prospector's letter, I would suggest that the triangular block of ore now left below and on the 'dip' side of the main gangways be partly removed and the space used as a small ore-pocket. The main ore-pocket would be situated near the intersection of the adit and the vein, and the ore from the small pockets on the incline could be brought here and trammed out of the adit cheaper than by hoisting through the slope which would entail a larger expense in maintenance and operation. Transporting the ore from the stopes to the main pocket could be done by a gravity-tram or by a balance system. A most important consideration is the filling of the stopes, which, if necessary, will be expensive. By the Prospector's system, for instance, which entails a series of raises and shafts at intervals and an accompanying tram service to the mill-holes (the raises), the cost must at least equal that of breaking the ore and the cost of production would probably be increased from two-thirds to double. This expense might be obviated by the use of experimental stopes which would ascertain just at what extreme stoping width the roof would stand for the requisite time, and this width could be adopted as a standard. The first two stopes, instead of being 60 ft. apart, might be started at an interval of 240 ft. and at the first sign of caving, as the ore was withdrawn at the *incline end* of the stopes, two more, 60 ft. apart, could be commenced between the first two, and 60-ft. pillars would still remain between these stopes and the first two. By the time the second series had advanced sufficiently, the first would in all probability have caved full and the third set of stopes constituted by the pillars above men-

tioned, might be started. In any case even were it found absolutely necessary to fill, at least 50% of the space could be left open, as the stopes, though still carried longitudinally with the vein, could be made narrower and only every alternate one filled.

In Mr. Nickerson's method of working the ground he speaks of filling the stopes with a raise and cross-cuts driven every 60 ft. as shown on his sketch. The smallest of these stopes, the triangular one ABD, would contain approximately 17,000 tons of loose rock, and as the raise and cross-cuts mentioned would produce less than 1,000 tons, a more elaborate system would be necessary; moreover it is probable that much shoveling might be necessary to remove the ore in the portion of the stopes below the crib-chute. The system of dropping all the ore directly through a main chute, however, to the adit, strongly commends itself.

D'ARCY WEATHERBE.

Berkeley, July 14, 1906.

BUILDING STONE IN CALIFORNIA.—Nearly every class of building and ornamental stone is found in California. Granite is quarried in Los Angeles, Madera, Nevada, Placer, Riverside, Sacramento, San Bernardino, San Diego, Tuolumne and Tulare counties over a range of hundreds of miles. Limestone is quarried in Amador, Calaveras, Colusa, Napa, Santa Barbara, Butte, El Dorado, Contra Costa, Los Angeles, Kern, Mono, Monterey, Placer, Riverside, San Bernardino, Inyo, Santa Cruz, Santa Clara, Shasta, Sonoma and Tuolumne counties. Marble is quarried in Amador, Riverside, San Bernardino, Inyo and Tuolumne counties. Sandstone quarries are operated in Colusa, Los Angeles, Santa Barbara, Santa Clara, Ventura and Yolo counties. Slate is largely quarried in El Dorado county. It is also found in several other counties. Serpentine occurs in a great many counties in large quantities, but has been quarried only on a small scale in a few places. It is quarried on Santa Catalina island, and as verde antique in San Bernardino county. Rubble and broken stone for macadam are quarried in a score or more counties. Porphyry is quarried for building stone at San Luis Obispo. Volcanic tufa is quarried in several places in Calaveras county, in Napa, San Luis Obispo and Sonoma counties. In this array of building stones there is a sufficiently wide range to give opportunities for the most fastidious builder. As a few striking examples of the adoption of local building materials in prominent California structures, it may be mentioned that the Post-office building at Seventh and Mission streets, San Francisco, has an exterior of Raymond granite. The three lower floors of the Fairmont hotel, on Nob Hill, are of Raymond granite. The first two stories of the W. H. Hellman building at Los Angeles are of Riverside granite. The buildings of the Stanford University are constructed of sandstone from quarries in Santa Clara county. The Kohl building, at the northeast corner of California and Montgomery streets, San Francisco, is of Colusa sandstone. The St. Francis hotel is of Colusa sandstone. The Dewey monument on Union Square is Raymond granite. Colusa sandstone is the material of which the exterior of the James L. Flood building, at the northeast corner of Market and Powell streets, is constructed.

THE mine-pump was the ancestor of the steam-locomotive. When coal-mining began to require unprecedented pumping appliances, attention became directed to the possibilities of steam. After the steam-pump had proved its capabilities, Trevethick and Stevenson invented a locomotive which was principally a steam-engine for pumping adapted to a new purpose and set on wheels.

Mining in Korea.

Written for the MINING AND SCIENTIFIC PRESS
By J. H. CURLE.

The Japanese, now in absolute control of Korea, are preparing mining regulations, with the idea of throwing open the country's mineral resources.

Of the known ore deposits, a number belong to the

the start, with no pay-ore. These concessions embraced what were presumably the best orebodies known to the Koreans. As only one concession out of three has returned the money sunk in it, the inference is that no large number of payable orebodies were known to exist in the country, and that tales of Korea's great mineral wealth must be received with caution. Personally I hold that opinion. I do not, of course, say that there are no more

payable mines in the country, but I think it is correct to say that at present no payable mines are known in Korea except those in the American concession.

I heard of half a dozen quartz lodes, in different parts of the country, where there is payable ore on the surface, or to the shallow depths to which the Koreans have mined; there are also some supposedly payable placer areas, and in the northeast there are copper mines which have been worked in a primitive manner. But nearly all these belong to the Household, and should the Japanese work these entirely for the benefit of the Korean Government, it will considerably narrow the field of enterprise for outsiders.

Coal is known in various

localities. I imagine that mineral, at least, may be closed to foreigners, for the Japanese Government itself owns the railways in Korea, and for commercial and political rea-

Aerial Tramway and Mill of British & Korean Mining Company.

Imperial Korean Household, and it is stated that these will be worked by the Government. The foreigners in the country, who are, as a rule, distrustful of Japanese methods, believe that these Household mines will eventually be given as concessions to influential Japanese financiers; they also say that Japanese will be allowed to locate all the known orebodies, under the terms of the new mining regulations, and that the other nationalities will find that there is nothing left worth having. This may, or may not, be so. Probably their fears are exaggerated; but I may point out here that even should all the promising mines pass into the hands of Japanese, they have, as a rule, neither the practical knowledge nor the capital to handle them, and in due time will decide to sell out or hand over control to English and Americans. Should we be so foolish as to give these people what they at first ask, or to buy unproved orebodies for big amounts of cash, it will be our own fault if we lose money in Korea.

Some years ago three foreign concessions for gold mining were given in Korea. Of these, the American has been a success; the English produced some gold, but is now worked out; and the German was a failure from

Unloading Station and Mill with Cyanide Plant under Construction.

sons may wish to control the coal supply. In brief, the value of Korean mines, outside the American concessions, is entirely prospective. Gold exists in numerous spots, and to a lesser extent copper, silver, and other metals, but nothing is yet proved or assured. Even if the country is thrown open, under a liberal mining law, and the Household mines either sold or leased on a royalty basis, it will

be some time before anything definite can be said about their value.

It is correct to say that mining conditions in Korea are excellent. The climate is healthy. In winter it is very cold, but dry; in summer there is heavy rain; spring and autumn are perfect.

Transport facilities vary. A railway now runs from one end of the country to the other, and is conveniently situated for some of the potential mines. Numerous tidal rivers can be utilized to a considerable extent; two such have been used to advantage by the American and English concessions. The roads everywhere are bad, and for some months in the rainy season they are impassable. The local transport is by means of bulls, but as many of these animals have lately died of rinderpest, there has been more or less disorganization and scarcity. This factor, as regard supplies of fuel and timber, has at times seriously interfered with progress at the American mines. Mules, imported from the States or China, do not seem to stand the climate and many die. Generally speaking, the transport factor is an uncertain one, and a position adjacent to either the railway or a river will mean a good deal.

The labor supply is superb. The Korean is the best

machinists, carpenters, blacksmiths, or engine drivers, Japanese or Chinese are used; the Korean is only in his element underground. Only a small staff of whites is required to run a Korean mine.

As to the factor of power, coal will be available for mines situated near the railway. Of wood-fuel there is a scarcity over most of Korea. The forests of the Yalu, on the northern border, would, of course, furnish all the fuel

Fine Grinding in Korea.

Natives Washing Gold.

colored miner I have seen, and for a wage of about 25 cents (gold) per day's work, he is but little inferior to a skilled white. In addition, he is most tractable. At times, in the plowing and harvesting seasons, there is a scarcity of labor; to obviate this it might be advisable to dump ore ahead, on the surface, so that the capacity of the mill should not be lowered. For surface work, as

required, but the lack of transport would in many cases make the cost prohibitive. A mine located near a tidal river could draw on the Yalu with advantage. Before the purchase of any Korean mine, this scarcity of fuel must be taken into account, and the mine's relation to a permanent supply assured. At the American mines, even owning, as they do, a large tract of country, the fuel question is going to become serious. The supply of trees is limited, and the mines are 60 miles from the railway. As for water-power, this can be successfully installed in numerous localities. At the American mines an installation generating about 500 h. p. is now at work; naturally, this will do much to ease the fuel problem.

As to mining timber, much the same position exists. Except on the Yalu, there is liable to be a scarcity in most localities.

At the American mines

soft ground and wide slopes have necessitated the use of unusually large square sets, and the timber resources of the adjacent country are, after a time, going to be severely strained. Here, again, the favorable situation of the mine will mean a good deal.

Water is, apparently, plentiful everywhere. I do not think the lack of it is a factor that need be considered.

As to the geology of Korea, very little, of course, is yet known; but there seems to be great variety in the occurrence of the orebodies. At the American mines the country is mostly granite. The principal orebody lies at a steep angle between granite walls, with, in one place at least, a width of 60 ft. of payable material. The length of the good ore is over 1,000 ft. and in the bottom, at 500 ft., there is no sign of falling off either in width or value.

Another mine on the concession is a blanket reef, about seven feet wide, lying on the granite; this is erratic in gold contents and a good deal broken, but still covers considerable area. The orebody worked on the English concession lay between limestone and quartzite; this was unusually rich for some depth, but held no pay-ore below about 400 ft. Excepting this rich patch, only low-grade ore has been found in Korea; for the average value of the American mines is less than \$6, and those who have sampled the unworked Household mines, or other prospects, as a rule have got equally low results. So little is known of the lodes that one is not justified in generalizing, but it would seem that a fair proportion of the quartz veins are fairly wide, say more than seven feet, which, to some extent, counterbalances their low average value. I did not see the copper deposits which have been worked by the natives, but understand that, though of high grade in places, the width is small. For gold dredging, the physical conditions would appear to be favorable on the whole, and as gravel deposits have been worked by the natives in various localities, there is reason to think that gold may exist in these in payable quantities. Some dredging ground is now being tested at the American mines.

So much for mining conditions. It may emphasize my remarks to give some actual figures from the working of the American mines to date. The concession is the property of the Oriental Consolidated Mining Co., of New York. Work started about seven years ago. Up to July 1, 1905, 869,275 tons had been treated for a yield of \$7.69 (gold) per ton. The present reserves are about a million tons, with an assay value of \$5.34. About eight mines have been developed on the concession. Most of these are now worked out, or nearly so, thus showing the usual characteristics. The two largest show the most evidence of permanence. All these mines were originally found and worked by Koreans; the company should now undertake to prospect thoroughly the concession for itself.

The concession is not well situated for transport. There is a scarcity of fuel and timber; but, as against this, there is water-power sufficient for 160 stamps. Cost of operations is increased by lack of concentration of plant, for there are five mills on the property, several being 20 miles apart. There are, in all, 220 stamps. In 1905, treating 257,647 tons, costs were as follows:

Mining and development	\$0.95
Tramming and milling	0.59
Treating concentrates	0.18
*Regrinding and filter-pressing are now being introduced.	
General (including tax to Korean Government equal to about 5c. per ton)	0.44
Total	\$2.16

Such figures are eloquent of the favorable mining conditions existing in this country. On a mine well situated for power and transport, with a seven-foot lode, a centralized plant and a mill of, say, 80 stamps, I venture to say that \$1.70 per ton would cover all expenses. With figures such as these, low-grade ore, if in quantity, becomes valuable; but, as I have before stated, the ore has got to be found first.

THE 'verdigris,' a greenish film which forms on the surface of amalgamating copper plates, is a hydrated oxide of copper, with sometimes a little carbonate. It is soluble in dilute acids, potassic cyanide and ammonia.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

All subscribers sending rocks or minerals for determination must give full name and post-office address. Those who give initials only need expect no answer. All samples should be carefully labeled, so that they may be easily identified.

The rocks from Santa Ana, Cal., are: No. 1, Diorite; No. 2, Diorite with a few indistinct crystals of feldspar; No. 3, Quartzite stained with iron and manganese oxides; No. 4, the same as No. 3, but more dense; No. 5, Limestone (impure, due to presence of earthy minerals and organic matter).

The rock specimens from Villa Grove, Colo., are determined as follows: The two light-colored rocks are Felsite through which are scattered a few feldspar crystals and an occasional partly altered hornblende crystal, and Marcasite (iron sulphide); the dark-colored rock is Diabase, in which the dark spots are augite crystals considerably altered. The bright, glistening lath-like crystals are plagioclase feldspar.

The samples from Phoenix, Ariz., are determined as follows: No. 1, marked Silver King. The granular portion of this specimen is mostly magnetic iron ore (Magnetite). The remainder is principally Hematite; pseudomorph after pyrite; that is, the mineral was evidently originally iron sulphide, now altered by oxidation to hematite, though the crystals still retain their original form. It is feebly magnetic. No. 2, marked Liberty, is practically identical with No. 1, being Hematite, altered from pyrite crystals, which are embedded in the original quartz matrix. These ores should be assayed for gold and silver.

THE SECRETARY OF THE INTERIOR recently rendered the following decision in regard to the contiguity of a mill-site to a mining claim, in the case of the Brick Pomeroy mill-site: It is held in the provisions of Section 2337 of the Revised Statutes that, "Where non-mineral land not contiguous to the vein or lode is used or occupied by the proprietor of such vein or lode for mining or milling purposes, such non-adjacent surface ground may be embraced and included in an application for a patent for such vein or lode, and the same may be patented therewith, subject to the same preliminary requirements as to survey and notice as are applicable to veins or lodes. The words 'vein or lode' in said section are not used in the restricted sense of indicating a body of mineral or mineral-bearing rock in place only, but are used in the larger sense of designating a located vein or lode claim, and that only non-mineral land not contiguous to a vein or lode claim may be appropriated for mill-site purposes. Directions are given that all applications for mill-site patents which may be made and carried to entry before July 1, 1906, or which may, by protest or otherwise, without the fault of the applicant, be prevented from being carried to entry before that date, where the locations of the claims were made and perfected under the law in all other respects prior to January 1, 1904, shall be adjudicated, in respect to the matter of contiguity of the mill-site claims to vein or lode claims, under the practice which prevailed in the general land office prior to the departmental ruling in case of Alaska Copper Company."

THERE is no greater mistake than the hasty conclusion that opinions are worthless because they are badly argued.

Some General Principles Governing the Operation of Mines.

Written for the MINING AND SCIENTIFIC PRESS
By J. R. FINLAY.

In the many scattered observations that have appeared in the mining publications of the last three years on the economics of mining, it is often stated as self-evident that varying conditions greatly affect the cost. Mr. H. C. Hoover says* rather vigorously, "I do not want some half-baked person to rise and remind us that the varying conditions (under which mines of different countries work, or mines of the same country for that matter, or even mines on the same vein or even different parts of the same mine) may render comparisons misleading. We all know that the factors which govern working costs are labor, supplies, size of orebodies, character of the ore, volume of ore treated, depth, etc., and that these factors are never precisely the same in any two mines, nor for any two months, and that *pro forma* comparisons may give the best man a black eye and put an inefficient man on a high pedestal."

This is all true enough and yet, after all, I doubt if many of us have given sufficient attention to these varying conditions that are so lightly taken for granted. I think that with respect to each of the various metals the conditions that vary average themselves into a sort of law which is simply expressed by the prices of metals. These prices are pretty stable and bear a fairly constant proportion one to the other. In ten years copper has sold between 10 and 18c. per lb., lead between 3 and 5½c., pig iron between \$10 and \$20 per ton, while gold has been assumed to be stable. Probably the variation from time to time in supply and demand is much greater, and affects the price far more than the variation in the cost of production. Hence it is reasonable to state that the cost of producing each of the principal metals is, within certain common-sense limits, constant. Now since the first requisite of a mine is that it shall pay, and since the percentage of profit at the most valuable mines is rarely as much as 50% of the gross value produced, it follows that the conditions in different mines and in different countries, so far as they affect the vital question of cost, are strangely alike.

Now what is the reason the metals have different prices and that these prices have a definite relation one to the other? Precisely because the percentage of metal in an average ore varies in a fixed rule with regard to the various metals. It is just as easy to handle a ton of gold ore as it is to handle a ton of iron ore. If the gold ore contained as much gold as iron ore contains iron, either gold would be as cheap as iron or else what little were mined would yield a tremendous profit to the fortunate discoverers. We all know that neither statement is true and I run the risk of stating a childish truism merely to draw attention to the fact that gold is not dear because it is hard to find, but because when found it is tangled up with a vast mass of worthless stuff. The separation from the worthless stuff is what costs money.

The proportion of metal in an average ore of each of the metals varies inversely as the price. Stated conversely, commerce dictates that ores of different metals are worth, on the average, about the same. If copper sells at twenty times as much as pig iron we find that the ordinary copper ore carries about one-twentieth as much metal as the ordinary iron ore carries. If we assume that the standard iron ore contains 50% iron, we can assume that the average copper ore contains about 2½% copper. In the case of lead, the ordinary price seems to be about six times that of pig iron. The average lead ore as mined probably carries about 8%. The occurrence of

silver and gold as by-products with this metal, introduces a frequent complication into the general proposition.

I regard it, therefore, as pretty well established that the price of metals is governed, not so much by the mere difficulty of finding them, as by the proportion they make of the rock-masses we call ore deposits. It is probably true that about as much money is spent annually to find iron as is spent to find gold; in either case the cost for finding the ore, while constituting an essential feature of the business, is not such as to have anything like a controlling effect on the price at which it must be sold.

I concede that everybody knows all this, but I think that in the literature of mining far too little attention has been paid to the logical deductions from the above facts. Let us state the case a little differently, comparing the normal ores of the leading metals, thus:

Iron ore contains 50% metal and 50% waste.

Lead ore contains 8% metal and 92% waste.

Copper ore contains 2½% metal and 97½% waste.

Gold ore contains 0.0015% metal and 99.9985% waste.

It appears at a glance that in most of the ores the proportion of waste is very high. To secure the metal, this waste must be rejected either by metallurgical or by mining process or by both. Probably too little attention is paid to the fact that a large part of this rejection may economically fall in the province of mining, and may very properly be charged as a cost of mining and not to metallurgy. When this rejection is undertaken by the mine, the cost of ore delivered over to the metallurgical process, whatever it is to be, will increase inversely in the proportion that the selected residue bears to the original mass, plus the cost of rejection. What the cost of mining should properly be in view of this proportionate rejection, is a problem that must be solved by the intelligent manager, not only for each mine, but possibly for each stope in the mine.

I have thought that mines divide themselves into three classes, as follows:

Class 1. Those deposits which by their composition and size produce ores that are ready as broken in the mine for the metallurgical process. To this class belong nearly all coal, iron and copper mines, and many gold mines, such as the Homestake and Treadwell, and even the Rand mines. The great bulk of mining operations as regards both tonnage and values falls under this class. In these mines the test of efficiency, providing, of course, for development sufficient to open the whole of the payable deposit, is the cost per ton of the ore or material raised.

Class 2. Deposits which contain a varying amount of concentrate of fixed grade. To this class belong some copper mines, such as the Baltic and Trimountain on Lake Superior, most lead mines throughout the world, typically those of southeast Missouri, also those of Joplin, Park City, and the Cœur d'Alenes. In this class the rejection of waste from ore that must be broken is often the most vital part of the mining process, hence the cost of mining the portion that finally goes to the mill may be several times the cost per ton of handling the orebody as a whole. In this class, the simplest test of efficiency is the cost per ton of all payable concentrate the deposit contains.

Class 3. Deposits containing a varying amount of concentrate of varying grade. The Cripple Creek gold mines are typical examples. Here the rejection of waste, to avoid heavy milling or smelting costs, may be carried economically to great extremes and, according to the ore, it may result in concentrates of enormously different values. It is plain that the possibility of securing a high valued product may render very expensive mining both profitable and economical. Here the only test of efficiency is the cost of extracting the payable metallic contents of the deposit.

In the second and third classes of mines it often happens that, owing to the matter of proper checking up of the variable factors, stopes are worked at a loss. This may be the case even where the mine as a whole shows good profits; indeed, it occurs often. Examples could be given of losing mines being made to pay handsomely by simply cutting out stopes that were too low-grade. In order to eliminate the unprofitable places, those places must be detected. To do this, it is indispensable not only to keep the costs of all working places, but also to find out what each place produces. The last requirement is the one most difficult to provide. A fair idea can usually be obtained by taking a grab sample from each car of ore from each working place. The average of these will give, if not the actual value, at least the proportionate value of the ore. By checking these results against the actual value of all ore produced by the mine for a given period, a trustworthy estimate can be made of the performance of each stope.

The following scheme of cost-keeping is applicable to a mine of moderate size in the second and third classes:

JOHN DOE MINING CO. COST SHEET FOR MONTH OF —, 19—.	Value of Product.	
	Loss.	
	Gain.	
	Value of product at working place.	
	Tonnage.	
	Total value per ton.	
	Cost of Operating.	
	Assays.	
	Total cost.	
	Cost for milling, smelting, transportation, etc., per ton.	
	Total cost for each working place in dollars and cents.	
	Cost of hoisting, blacksmithing, pumping, lighting, superintendency, general expense, etc., all figured as an average for mine at so much per ton.	
	Detail of costs for explosives, machine drills, timbers, etc.	
	Detail of labor cost for each place, as desired.	
STOPING.		
Horizontal line, one for each working place.		
Total of stopes.		
DEVELOPMENT.		
Horizontal line for each development heading in mine.		
Total for development.		

Space here for memoranda of expenses of home-office and also for actual money-returns of all ore shipped in the month.

(In practice this forms a big sheet, too large for reproduction here. This is only an illustration of the scheme).

This scheme of cost-keeping is based on the recognition of two divisions of expenditure: (1) The labor of miners, trammers, and timbermen, together with the supplies they use, forming expenses that can be charged directly and accurately to individual working places. (2) Expenses like hoisting, surface expense, superintendence, general expense, which belong to no particular stope but can be charged indiscriminately at so much per ton to the entire product. By keeping the time and issuing supplies on the above plan, the costs can be arrived at

easily and, at the same time, comprehensively. In practice, the working out of the cost of the various stopes invariably shows great discrepancies. Concurrently, the values of the product from various parts of the mine will also prove to be discrepant. By combining the results one ordinarily gets information of great usefulness.

But it is not to the details of this system that I wish to draw attention, but to the general principles; that:

(1) In orebodies of the same value, the question of how the value is distributed largely controls the part to be played by mining as against metallurgy in the extraction of the metals.

(2) In mines of the first class, economy means only a low cost per ton, obtained by the handling of large masses of uniform material, lumping everything together to save expenses, keeping the output in one unit. The cost to be kept is the average of the mine worked out in great detail.

(3) In mines of the second and third classes, economy demands that ores shall be kept separate and accounted for separately. The average cost should be arrived at only as a final result from the addition of the individual stope records, and is not by any means a valuable or decisive guide to efficiency of management.

COPPER IN THE ZUNI MOUNTAINS.—According to F. C. Schrader, of the U. S. Geological Survey, the Zuni mountains form a group about 20 miles long and 50 miles wide, situated some 85 miles west of Albuquerque. They are composed of pre-Cambrian schists, gneisses and granites, and are flanked on all sides by gently upturned strata regarded as of upper Carboniferous age—the 'red beds' of the Colorado plateau region. Copperton, the principal mining camp, is situated in the heart of the mountains, 20 miles west of the Atlantic & Pacific Transcontinental railway. Copper deposits are found both in the pre-Cambrian rocks and in the lower strata of the 'red beds.' In both situations the ores thus far revealed consist almost entirely of secondary copper minerals, including green and blue carbonates and copper glance. Chalcopyrite, though present, is uncommon. In the pre-Cambrian the ores occur along sheeted zones in the schists or gneisses, sometimes associated with quartz in irregular vein-like bodies, but to a greater extent disseminated through the rocks of the mineralized zones. These zones vary in width, the widest observed being 800 ft. across. They are often persistent for considerable distances, and in several instances the presence of workable amounts of rock carrying above 3% metallic copper has been demonstrated. The usual minerals associated with these ores are quartz, specular iron, limonite, galena and pyrite. Gold is present to the extent of \$1 to \$4 per ton. The basal strata of the 'red beds' which carry copper minerals are from 30 to 60 ft. thick. At the bottom is an arkose conglomerate and above this there are layers of sandstone and shale. In the northwest part of the district the conglomerate may be seen resting upon the basalt edges of the crystalline pre-Cambrian rocks. The ore minerals are locally disseminated through the rocks, and where occurring in the conglomerate appear to have been deposited with the sand and gravel which compose the rock. If this suggestion is correct, the copper minerals were probably derived by erosion from the pre-existing deposits in the crystalline formations. The ore-bearing strata, and especially the shaly beds, contain considerable amounts of fossil wood, and this material has been largely replaced by copper carbonates and glance. The district has been under development for about five years, but as yet there are no shipping mines. Annual assessment work is done on some 200 claims controlled by about 75 individuals. The region is well watered and forested, and the climate is a pleasant one.

Three Weeks in Mexico---III.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

There was not much geology to be deciphered along the railroad from Vera Cruz to Mexico City, except the wonderful constructive features to which the Sierra Madre Oriental and the great Mexican tableland owe their origin. The plains of the coast are made of Tertiary sedimentaries, from the actual dunes of the shore to the foothills of the Sierra Madre, where the railroad enters the Middle Cretaceous, the rocks of which are largely covered by the lava emitted from young volcanoes. At Penuela there is a quarry of Middle Cretaceous limestone, which is the stone employed in building the mole and breakwater at Vera Cruz. Coming west, between Maltrata and Boca del Monte, the railroad cuttings expose intensely folded strata, traversed by faults that divide the Cretaceous series in step-like succession.

A Basket Store.

Above Boca del Monte, the sedimentaries are crowned by remnants of lava streams and volcanic dust, in part consolidated as tuff and in part loose earth, but hardly warranting the idea once prevalent that it had been accumulated by wind or, in geological phrase, was of eolian origin.

Through this volcanic material, hummocks of the Cretaceous make an appearance, as at San Andres. The rest of the journey to Mexico City is made over plains broken by occasional rocky domes and carpeted with volcanic scoria, tuff, and *malpais*.* Such a formation of volcanic dust is often termed 'ash.' Ash is the product of combustion; this material is the result of violent explosion or fragmentary ejection from the vent of a volcano; it is broken rock, which has undergone grinding by abrasion due to the collision of particles in mid-air. It is, therefore, 'dust,' that is, minutely subdivided rock. This material, call it what you may, is of interest to the miner, because occasionally, when mixed with the products of the decay of other more ancient rocks, it carries gold. Near Jalapa a large area is said to give assays of one to four grams gold per metric ton, or per

2,000 lb. Two grams is claimed to be an average and as this material cyanides readily, it may become commercially valuable. An analogous occurrence is found in the massive volcanic rocks of the ranges northwest of Mexico City, where both the precious metals exist along zones of fissuring, to the extent of one or two grams gold and nine grams silver per ton. The metals have been detected in places where solfataric action is in evidence, especially along cracks in the solid hypersthene and hornblende andesites. The richest material is found in a concretionary form, together with hyaline silica, resembling the glassy quartz of ordinary gold veins. The waters doing this work are cold. It is probable that the gold and silver are derived from the decomposition of the iron pyrite that abounds, finely disseminated, in minute

In the Patio of the Hurbide Hotel.

crystals, throughout the rocks of these localities. Minute crystals of hematite have also been distinguished, more usually in the rotten rock. It can also be said that the greater the decomposition, the greater the concentration of gold and silver in the cracks traversing this formation. In the dry climate of the Mexican plateau, meteoric water dissolves the carbonic acid and, sinking below the surface, it exerts a solvent action. In the Guadalupe range, five miles north of the City, there are narrow solfataric vents, the warm waters of which have deposited silica in the form of quartz together with gold and silver, the first in traces and the second to the extent of eight grams per ton. These occurrences, while of no immediate commercial importance, are interesting as affording present-day manifestations of the manner in which thermal waters make ore. The same process continuing for a long period, and protected from erosion, would lead to the creation of a valuable ore deposit.

One hears much of the sulphur in the crater of Popocatepetl and a company formed to exploit these deposits of hyponitrate has obtained some notoriety. Not long ago, Senors Jose G. Aguilera and Ezequiel Ordóñez

*This is the word that in its corrupted form, *malpais*, is used in Arizona and the Southwest generally, to designate the black lava-fields. It comes from the Spanish *mal*, bad, and *pais*, country.

descended into the crater and found a deposit of sulphur not more than 15 cm. thick and so distributed as to be of no industrial value. Although exceptionally pure, the sulphur was in the form of small particles mixed with volcanic dust around cold fumaroles; these emitted steam with traces of sulphuric acid, the decomposition of which led to the precipitation of the sulphur. It was the result of deposition for a period of twenty or thirty years. There is a story—and it is Prescott who tells it—of an ascent of Popocatepetl, made by some of the men with Cortez, to secure sulphur; but these explorers did not go to the bottom of the crater, which is 800 ft. below the summit; they went only as far as a fumarole on the lip of the crater. After all, the quantity of sulphur which they needed—and they took—to make gunpowder, was insignificant.

Mexico is the Paris of the American continent. The air is clear and balmy with the feel of the tropics, the early mornings prompt a canter on horseback in the park at Chapultepec, the story of the City gives it the dignity of history and the glow of romance, the actualities of today are touched with the silken hand of luxury; life is rich, gay, and progressive. The brutality of mere materialism and the squalid splendor of newly made wealth are not evident, the invasion of Anglo-American energy and capital has prompted many sanitary reforms and municipal improvements, but the practical man from the North is insignificant in numbers, so that while he may be partly responsible for the cleanliness of the streets, he is unable to spoil the distinction of a community, the members of which go to Paris as to the Lourdes of a fashion saint, bringing home a taste in clothes and horses that enhances the attractiveness of the daily promenade and gives grace to the Spaniard and distinction to the Mexican. Time was when the City of Mexico was far from salubrious, when her streets were badly paved and her hotels among the worst of their kind; but all that has been changed. Of comfortable hostelries there are plenty; the restaurants afford a great variety of good cuisine, and the clubs—the Jockey, the British, the American, and several others—give sojourners the hospitality worthy of a metropolis.

There are many fine buildings in the City. The cathedral and the museum are well known to travelers; the building in which the School of Mining is now situated is more than a century old, and it is full of interesting traditions. One of the founders was Andres Manuel Del Rio, the great Spanish mineralogist, who adopted Mexican nationality; he belonged to the Freiberg school and during Humboldt's time was sent by the Spanish government to Mexico with a view to stimulating mining education. He founded the collection now to be seen in the School of Engineering, which includes that of Mining. There is a story told of Del Rio and Humboldt that is not without humor. Del Rio found a new mineral which he called *plomo rojo de Zimapan* or red lead; it was a vanadate of lead, vanadinite. Humboldt visited Mexico at that time—between 1804 and 1808; Del Rio gave him a specimen and his notes concerning the discovery of the new mineral. Humboldt took them to Europe with him; subsequently, he wrote to say that he had lost these notes and the specimen in some boxes that fell overboard at sea. But, strange to say, some years later the vanadium mineral was discovered in Scandinavia. In 1836 Del Rio made a sarcastic reference to the episode in a paper which he wrote as a sort of protest against the injustice done to him, in calling the new metal after the Scandinavian goddess instead of—for example—Riita. For his was the discovery.

In the museum there are some fine meteorites; one specimen weighs 14 tons; it came from Chihuahua.

Another, called the San Gregorio mass, has inscribed upon it the following Spanish rhyme:

*Solo Dios Con su Poder
Este hierro destruya
Per ee en el Mundo no Abra
Quien lo pueda Defueer.*

I trust no scholar, critical of the Spanish of this quotation, will impute its apparent errors to me. I give the words exactly as I copied them from the inscription. Which may be interpreted: "Only God with his power can destroy this iron, for there is no one in the world who is able to unmake it." It was discovered in the year 1600 and weighs 10,000 kilo.; the locality whence it came was San Gregorio, in De Allende district, Chihuahua.

From the observatory on top of the building there is a splendid view of the city and its environs, especially eastward, where the towers of the cathedral and the domes of the churches of the Profeso and Santa Teresa rise finely above the multitudinous buildings, cut into squares by straight streets, beyond which are the dark foothills, dominated in the distance by the broken crest of Ixtaccihuatl and the big cone of Popocatepetl. To the south-east, one can see Iztapalapan—now Istapalapa—where, on the eighth of November, in 1519, Hernando Cortez met Montezuma, and the pioneer of European invasion exchanged courtesies with the poor king whom he so utterly destroyed within less than a year.

At that time Iztapalapan was a place of twelve thousand houses and it was under the rule of Cuiclahua, the brother of Montezuma. Through the town passed one of the three great causeways that led across the lake to the City of Mexico itself, and it was over this causeway that the Spanish adventurers made their way. Today Istapalapa is a small village and where once spread the waters of the lake, there is marshy ground. The causeway is obliterated by a modern street, that of Acequia, which took advantage of the secure footing thus afforded. It starts from the portals of the Plaza de la Constitucion, as does also, in the opposite direction, northward, the San Andreas street, which merges in the road to Atzeapotalco; this was the line of the causeway to Tlacopan or Tacuba along which the Spaniards retreated on the occasion of the *noche triste*, that black night of July 1, 1520, that saw them all but annihilated by the fury of the Aztec populace. At Popotla the survivors halted under a tree which survives to this day. It is now guarded by an iron railing, but despite even this protection I read in the daily paper, during my visit, of the arrest of a vandal who wanted a piece of the bark to add to his collection of curios. If ever there was a time in the Spanish conquest when Cortez and his fellow pirates were heroes indeed, it was just after their sad halt at Popotla. Of the number that had entered the City only a third (250) of the Spaniards survived and of their native auxiliaries one fifth (1,000). They had lost most of their horses, all their artillery, all their muskets, so that there remained only their swords and their courage. But Cortez faced the music like a man and was confident even in the hour of deepest gloom. Scarcely one week later, on the plain of Otumba, this handful of men met a multitude of natives, estimated all the way up to 200,000, and beat them off the field, mainly by reason of the desperate resolve of a few of the cavaliers who followed the immediate lead of Cortez and penetrated the thick of the combat in order to kill the chieftains on the opposite side. It may have been comparable to the attack of a centre-rush of a senior football team into the midst of a kindergarten, but it was magnificent by reason of the disparity of numbers and the proof of a superiority of race that was not all physical.

It is a fact, both significant and pathetic, that while

there are today several statues to the last Aztec king—Guatimotzin or Cuiclahuac—more particularly the fine monument in the Paseo de Reforma, and while nearly every city in Mexico has a bust of Hidalgo, the priest who started the final revolution against Spanish rule, there is no statue to Cortez in the whole length and breadth of Mexico.

THERE are various ways of separating gold and silver from metallic copper and from copper-matte. One method is that known as the Hunt & Douglas process, in which the matte is roasted at low temperature, so that copper sulphate and oxide form without producing any silver sulphate. It is then leached with dilute sulphuric acid, the gold, silver and lead remaining in the residue. The copper solution is chloridized by adding calcium chloride and the copper precipitated as sub-chloride by passing sulphurous acid through the solution. The sub-chloride of copper is reduced to sub-oxide by milk of

lime, whereby chloride of calcium for further use is recovered, while the sub-oxide of copper has only to be reduced to metal. Another process is that invented by Block & Hartman, for the separation of gold from copper-matte. The matte is roasted to convert the silver present to sulphate, after which it is leached out with water and

precipitated on metallic copper, the gold remaining behind in the matte. The residue containing the gold and copper is concentrated in a reverberatory furnace until a small amount of copper is extracted as a copper-bottom which carries nearly all the gold. This gold-bearing copper may be fused repeatedly with pyrite—auriferous or not—and the copper gradually turns to matte, while the gold continues to remain with that portion of the copper that is still metallic.

EDWARD FORBES used to say that no one who has dredged much can ever wonder at so many rocks being wholly devoid of organic remains.

The Statue to the Last Aztec Emperor.

Popocatepetl.

Our New Machine Drill. A Story.

Written for the MINING AND SCIENTIFIC PRESS
By W. H. STORMS.

We had been running our mine for several years—in fact, since it was first opened, by hand drilling entirely, but as the workings were carried deeper the rock was found harder. I had recently been sent out to take charge of the mine, and I finally decided to put in a compressor and machine-drills to hasten the driving of our cross-cut tunnel. The plant cost several thousand dollars, but we didn't care so much about this, as we expected to save a lot of money by the use of the machines. After the usual delays our compressor was set on its concrete foundation, and connected with the water-wheel pulley by belt. The compressor was placed several hundred feet from the tunnel, being situated down near the bottom of the gulch to take advantage of the additional pressure of water. Finally everything was in readiness and our machine-man set up the drill in the face of the hard cross-cut, and the work began. We were fortunate in having an experienced drill-runner. He told me he understood his business thoroughly. After the machine had been working, perhaps 15 minutes, and he had drilled the hole so deep that he had to change the first drill—the 'starter,' he called it—for a larger one, the machine suddenly stopped. It 'bucked' a little, hissed and coughed once or twice, started up again, struck half a dozen blows with lightning rapidity, and again stuck hard and fast. "Hit it!" shouted the machine-man to his helper, who stood, wrench in hand, enjoying the performance.

Before I could stop him, this fellow, the chuck-tender, hit the drill a couple of heavy blows. "It's all right," said the machine-man, in explanation to me. "That's the way we have to do." Then turning to the chuck-tender: "Take the hammer." The latter grabbed up a double-handed six-pound hammer and commenced industriously to beat the drill, about midway between the chuck and the face of the drift. After several lusty blows, which I feared would break something, to my surprise, the machine started again, and ran a little while without further trouble. But just about the time I had made up my mind that everything was all right, and we would have plain sailing, she stuck again. The machine-man muttered something I didn't quite catch, but it sounded to me a good deal like profanity. "Here," he said abruptly to the chuck-tender, "Grab a holt of that wrench and loosen up those clamp-bolts a little." He re-adjusted the machine on the bar, showing that he understood his business. The bolts were again tightened, and drilling proceeded with another new bit, for some minutes, when the machine once more became erratic, acting much the same as before, but by dint of the lusty hammering on the part of the chuck-tender, and expert manipulation of the air by the runner, the work proceeded until something fell from some place overhead. We all looked up, and then all looked down to see what had fallen. It was a piece of a wedge that had been driven between the head board and the back of the drift.

"I knew that that was what was the matter," hotly exclaimed the runner, cursing roundly this time. "You didn't wedge that bar tight enough," he continued, scowling at the chuck-tender.

"You drove the wedges yourself," said the chuck-tender. "Why don't you twist up that screw and make it tight?"

The drill runner only glared at his assistant. Together they screwed up the column-bar till it would ring like a bell.

We had no further trouble with that hole, and not a great deal with the others. During that shift the new machine drilled 30 ft.—five 6-ft. holes. As we were then

prepared to run only one shift a day with the machine, the remainder of the round was completed the following day. We put in 12 holes, each six feet long, in that face. The drift was about five feet wide and seven feet high. The holes were all charged with plenty of dynamite, and the entire round fired. When the smoke had cleared away a little we rushed back, but there must have been something wrong because there was not more than half a car of rock broken and the entire round of holes still stood in the face.

I expressed my astonishment, for I had been told that mining with machines was much cheaper than by hand work. The machine-man, however, was wise, and without hesitation assigned the difficulty to the inferior quality of the powder.

I told him it was the same powder we had been using, and then he explained to me that "the powder had been too long in the mine and had got frozen." I hadn't noticed any marked decrease in temperature in the mine, but acknowledged his superior judgment and experience.

"We'll just shoot 'em over again," he remarked. "We will break her all right."

Thus re-assured I gave orders to bring down more powder, but I had lost much interest in the proceedings. My eyes were smarting and I was feeling badly—suffering from a nauseating, violent headache, which seemed to momentarily get worse. I groped my way out of the tunnel. The fresh air was most agreeable, but my headache seemed worse each minute. I had a bad case of 'powder-head.' After some time I heard the dull boom of repeated shots fired at the face of the tunnel. Nearly an hour later one of the men came to tell me the round had done a little better and Joe was going to fire the holes once more. Joe was the machine-man. I felt too sick to care very much what he did, but told the man it was all right. The following day we started in on the second round, and made fairly good headway. This round was completed the next day and fired just about quitting time in the evening, but something was still the matter with that powder, for we had no better success than before. I concluded not to do any further blasting until I could get some suitable powder.

The next morning as I was about to enter the tunnel a man walked up and asked if there was any show for a job. I liked his looks, and inquired if he knew anything about running machine-drills. He answered simply "Yes." I said I had one good machine-man, but had been wanting to get another, so that we might run two shifts. "Just now," I explained to him, "there is something wrong with our powder. It is frozen, or something, for it don't break the ground." "That's curious," he said, "I should not think powder would freeze here at this time of the year."

"Well," said I, "if you like you may come in and have a look at the result of the last round we fired last night."

We entered the tunnel together, and after walking several hundred feet reached the face. Here we found twelve horizontal holes bored in the face. They had been fired the night before, but had acted much the same as in the instance of the first round—only a few inches of the collars of the holes had been broken. The stranger looked at the face, seemed amused at something, and asked for the spoon. He inserted this instrument in each hole in succession, feeling round with it as carefully as a dentist probing in the cavity of a sensitive tooth of a wealthy patient. When he had inspected each hole of the round, he said, "I should not expect these holes to break very well."

"Why?" I inquired.

"You didn't give them any chance," he replied. "You never drilled any cut holes."

"Cut holes?" I repeated after him. "What are cut holes?"

"Holes drilled like this," he replied, showing the direction of the proposed holes with the spoon. "I think," he said, "I can make that round break all right by drilling a couple more holes here," indicating the place.

"All right," I replied. "Let us try it."

Just then Joe came in with a box of powder, to recharge the round of holes. I told him we intended to experiment a little by drilling a couple of more holes, and he might take the powder away again. He did not seem over-pleased, but said nothing and retired with the powder. Meantime the other men had carried up the machine and in a short time the new man had set the bar horizontally across the drift and had clamped the machine to it. In what seemed to be an incredibly short time, he turned on the air and began drilling. The first hole was drilled about 30 in. without a stop except to clean out the drilling and to change drills. The machine was shifted and a second similar hole drilled diagonally to meet the first. The stranger said he thought the round would break now all right, but it would be better if two others were drilled near the bottom. However, he thought it safe to try the round as it stood. The holes were charged and fired by the new man. After waiting a proper time—on which I insisted—we returned to the face and the place was heaped up to the back with broken rock; the round had broken. On returning to the office I saw Joe sitting on the steps. As I came up, accompanied by the new man, Joe got up and said, "I guess I'll take my time."

"What for, Joe?" I inquired, somewhat surprised.

"Oh, I think I might as well leave. I guess you've got a better man."

It had begun to dawn on me some time previous to this that Joe was not the expert he had led me to believe he was; but he had many good traits, he was a worker, and I had no desire to discharge him, so I said, "Joe, how long had you run machine-drills before you came here?"

He looked sheepish and with a grin replied, "I never run a drill before, sir, but I tended chuck for a couple of weeks once, and I was awful anxious to get to learn."

"Well, Joe," said I, "you can tend chuck here and learn to be a machine-man, and after a while you will be all right."

On the advice of our new man I bought another machine, and he taught both Joe and his partner how to run them. They drill 50 to 60 ft. per shift now, and seldom fitcher a hole. The stranger is my foreman and he is a good one. I am also learning a few things myself.

A NUMBER of accidents which have occurred recently to British fishing vessels have been attributed to the magnetized condition of the sheath-knives carried by the sailors. Iron, as is well known, is easily magnetized and may acquire considerable strength due only to the earth's field. If it be used anywhere near a dynamo or motor it is almost sure to become strongly magnetic. Now, it has recently been discovered that the sailors' knives may become magnetized so strongly as to influence considerably the ship's compass and that the wrecks referred to above have been brought about in this way. It has been suggested that the sailors be supplied with knives of non-magnetic material, when the danger will at once disappear. Here is an opportunity to revive the so-called "lost art of tempering copper." *Electrical Review.*

GOLD is green when in very thin sheets and seen by transmitted light. When leaf gold is heated to 316 degrees C., the green is turned into a splendid ruby color.

Corporations.

A 'stock corporation,' formed to carry on a mining, manufacturing or mercantile enterprise, is called a 'business corporation,' to distinguish it from a company formed for banking or insurance, termed 'moneyed corporation,' and from a railroad, telegraph or telephone company, called a 'transportation corporation.' These latter corporations are usually subject to stricter regulations than 'business corporations,' but enjoy more extensive powers.

The principal advantages of corporate form are:

1. The limited liability of stockholders in case the company fails.

2. The simplicity and convenience of dividing the capital into shares represented by certificates and transferable by indorsement, that is, the ability of selling out and buying into a company.

3. The continuance of the organization in spite of change, death or insolvency of its members.

4. That while a subscriber to the stock of a company is liable to the fully paid value of the stock, neither he nor any buyer of that stock, is thereafter liable. It is a great advantage, in investment in stock, that it is possible for a man to engage in corporate enterprise and to know at all times exactly how much he is risking. This is not true of a partnership.

The stock of corporations can be classified thus:

'Common' stock is the general or ordinary stock of a company without special privileges or restrictions.

'Guaranteed' stock is that of one corporation, the payment of the dividends of which are guaranteed by another company.

'Full-paid' stock is that the full value of which has been paid in cash, or has been issued in payment for property without fraud and in good faith.

'Unissued' stock is in itself a nullity, and until issued, represents nothing. It is not treasury stock.

'Issued' or 'outstanding' stock is that which has been bought or subscribed for and the subscription accepted by the company, or which has been exchanged for property, labor, services or other values.

'Watered' stock is that issued without payment or without full payment therefor in cash or in property.

'Preferred' stock is that which receives a specified dividend before common stock can receive any. Its holders may, or may not have the privilege of voting. It is possible for a company to have two or more classes of preferred stock, each drawing a different percentage, the dividend of one class being paid before that of the other. Preferred stock is sometimes arranged to first draw its preferential dividend each year, then to participate in any further dividends declared that year; or, on the other hand, the common stock may draw a dividend equal to that of the preferred stock, and then both stocks participate equally in any further dividends of that year.

'Cumulative preferred' stock. Not only must the dividend on this stock be preferred, but, if profits do not permit its payment at any given year, the lacking amount must be paid out of the profits when they later accrue before dividends can be paid on common stock. This is sometimes called 'guaranteed' stock.

Sometimes it is provided that preferred stock may be redeemed at a fixed price after a term of years, or that it is to have preference in the distribution of assets upon dissolution of the corporation.

Have something to say, and say it, was the Duke of Wellington's theory of style; Huxley's was to say that which has to be said in such language that you can stand cross-examination on each word. This was the secret of his lucidity.

Self-Dumping Skip.

Self-Dumping Skip.

We give herewith the drawings necessary to illustrate one of the latest designs of self-dumping skips. The weight of the skip is 600 lb., the sides are made of steel sheets 3-16 in. thick, the bottom being $\frac{1}{4}$ in. thick. There is a wooden false bottom covered with No. 10 plate. The bale is made of $\frac{3}{4}$ by 3-in. Norway iron. The capacity of the skip is 2,500 lb. Willis Lawrence invented this device and Frank Oliver, superintendent of the Florence-Goldfield mine at Goldfield, Nevada, designed the arrangement, and we learn from Mr. Oliver that in raising ore from the 250-ft. level, discharging into the skip from bins at that level, four tons were hoisted in five minutes, 30 h.p. being indicated on the electric hoist. At a recent trial 34 tons were raised in 45 minutes, including the time taken in changing from three levels, namely, at 150, 200 and 250 ft. From the 150-ft. level the average time was 20 minutes in raising 20 tons. Among the good features of the design are these: The weight of the skip is small for the load it carries; the skip and its load are carried by the yoke and there is no weight on the axle; the dumping is expedited.

WASHING SANDY MESABI ORES.—Experiments in the washing and mining of soft, sandy ores of the western Mesabi are still in progress, and the Oliver Iron Mining Co. has ordered a lot of machinery for working these ores. It expects to mine and ship 1,000,000 tons a year or more from one location on the western Mesabi. Every device for handling these ores, both for mining at low cost and for concentrating, is being tried, and without doubt the results will prove exceedingly valuable to all mining men interested in moving and dressing ores on a large scale. Some very interesting new devices for mining may be adopted in this district, and if they prove successful methods of stripping, depths and the general handling and removal of earth and ore may be revolutionized. Three steam-shovels are stripping the Stephens mine on the eastern Mesabi, where developments have been in progress for several years. The mine has been developed in a model way for a very heavy output, but it only produced 87,000 tons in 1903 and 367,000 in 1905. It is capable of an annual product of more than 1,000,000 tons, and so large is the ore deposit that this can be maintained for much more than a generation. The royalty is low, 15c. per ton, which may account for the slight output so far. The annual stipulated minimum is 100,000 tons.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

PULVERIZING-MILL.—No. 823,127; Stephen R. Krom, Plainfield, New Jersey.

In a pulverizing-mill, the combination with a shaft, a revoluble device, a series of roller devices mounted thereon, and a fixed ring having a crushing-surface against which the rollers bear, of a tubular hub structure mounted on said shaft and having triangularly arranged faces and perforations, a series of curved tapering hollow centrifugal feeders secured upon the triangularly arranged faces of the tubular hub and curved rearwardly or in the direction of rotation, the discharge-apertures thereof coming adjacent to the crushing-surface and in front of the path of the rollers, a hopper, means for supporting the same, the forward extension of the hopper forming a bearing, a tubular inner prolongation of the hopper communicating therewith, the free end of which passes into the aforesaid tubular hub and is provided with an aperture, a screw conveyor and a shaft therefor within the tubular prolongation of the hopper, and means for rotating the same, for progressing the material to be pulverized and delivering the same through the aperture to the hollow centrifugal feeders.

MAGNETIC SEPARATOR. No. 823,303; Frederick T. Snyder, Oak Park, Illinois.

In a magnetic separator, the combination with a hollow iron cylinder having permeable projections thereon, of an electromagnet having a pole-piece external to said cylinder and facing the same, the face of said pole-piece being bare, an energizing-winding upon said pole-piece, a body of magnetic material forming a return magnetic circuit from the rear of said pole-piece to the inside of said hollow cylinder, and means for passing material to be separated between the surface of said hollow cylinder and the face of said pole-piece and into contact therewith.

MAGNETIC ORE-SEPARATOR.—No. 823,234; H. H. Wait, Chicago, Illinois.

In a magnetic separator, the combination with a hollow magnet, open at top and bottom, of bare poles of opposite polarity on said magnet, the face of one of said poles being vertical, a shaft adapted to revolve between said poles, having bearings mounted on neutral sides of the magnet, an armature, mounted upon said shaft, permeable projections on the surface of said armature, said projections being of such shape and spaced from said vertical pole such a distance, that material will be attracted from said pole to said projections, a divider mounted adjustably on said shaft, a hopper hinged to said divider, an apron hinged to said divider, and engaging another hopper, links attached to said divider, means for moving said links, means for rotating said armature, and means for feeding material to be separated to said armature.

MINING APPARATUS.—No. 823,960; Alexander McDougall, Duluth, Minnesota.

A mining apparatus comprising a mine having water therein, a scow floating therein, a suction pump carried by the scow, a pipe leading from the pump into the water, a partly flexible pipe leading from the pump to the dump, a reservoir receiving the water from said dump, a pipe in communication with the reservoir and the pump on the scow and adapted to operate the pump, and a pump adjacent the pit and adapted to draw the water from the mine and discharge it into the reservoir.

BLAST-FURNACE.—No. 824,485; W. Kemp, Tucson, Arizona.

In a furnace, the combination of a smelting-chamber, twyers for delivering air therinto, a conduit for feeding coal to said furnace, branch conduits connected with said conduit and opening directly into said smelting-chamber, spiral feed-screws mounted within said first-mentioned conduit and adapted to distribute said coal through said branch conduits, and separate pipes connected with said twyers and with said branch conduits.

An Amalgamating Machine.

The saving of fine gold is a question that is always of interest to mining men. The lessees of the Smuggler-Union mill, near Telluride, Colorado, have installed twelve 20-ton Pierce amalgamators below their plates, and during the months of February, March, and April these machines saved 1,003 oz. gold worth \$12 per oz. at the U. S. Mint. The mill consists of 12 batteries of five stamps each, and at the end of each plate one of the amalgamators receives the pulp, which then goes to the concentrating tables, and from there to the cyanide-plant. There is an extra Pierce machine on hand, so as to permit of a clean-up without stopping the battery. The amalgamator occupies but two to eight square feet, according to the size of the machine, and has a length of 11 to 14 ft. of amalgamating surface.* It is made of varying capacity and is suitable for any mill, as there is no splash required. In many cases it is set below the mortar instead of using plates, or it can supplement the plates as at the Smuggler-Union. It is also used in placer mining and on dredge-boats and in cyanide-plants. The riffles, used in the machine, are made of copper, either amalgamated or silver-plated, as desired. The riffles are held in place by holders placed in an iron box, which has a slope of from two to four

Pierce Amalgamator.

inches per foot, according to the material to be run through. As the accompanying illustration shows, the lower riffles are bent something like the letter Z. At the top, the copper is bent back so as to form an air space; the bottom of the riffles is turned up at each end and brazed, so as to hold quicksilver. The upper riffles can be made of wood or, preferably, copper. All gold, sand, and water passes through the boxes underneath the upper riffles and over the under riffles. As the pulp passes into the riffle box, it fills to the tops of the first riffle, and then passes under it, between the first lower riffle and then between the first and second upper riffles, and to the top of them, then between the next lower riffle, and up again, and through the second and third upper riffles, and so on between all of the riffles to the end of the box, the gold adhering to the riffles, also sinking into the quicksilver, while the sand and water are thrown out. These machines are being manufactured by L. S. Pierce, at Denver, Colorado.

Commercial Paragraphs.

THE San Francisco office of the PACIFIC TANK Co. is again at its old quarters, 301 Market street.

THE Pacific Coast office of the WELLMAN-SEEVER-MORGAN Co. has removed from its temporary location in Oakland and is now permanently located in the Atlas Bdg., 604 Mission St., San Francisco, California.

THE DEREMER WATER WHEEL Co., of Denver, has shipped water-wheels to the following: One Special phosphor-bronze 12-in. motor to operate under an effective head of 770 ft. and develop 100 h.p. for the Bingham Metals Mining Co., Tooele, Utah. Six special 20-in. water-wheels, in batteries of three each, forming one unit of power for the High Creek E. L. & P. Co., Richmond, Utah. One 6-ft. water-wheel for the Bunker Hill Con. mines, Austin, Nevada. This wheel was delivered on a rush order for express shipment. Two 6-ft. double-nozzle water-wheels for the Hancock Gold Mining Co., Alpine, Colorado.

THE PELTON WATER WHEEL Co. has practically completed its new works at Nineteenth and Harrison St., San Francisco, and will be in complete running order by Sept. 1. These shops were under construction before the fire, according to plans carefully prepared; consequently, they are to be permanent—not designed under emergency conditions—and will afford the most modern facilities for handling and turning out high-grade work.

THE United States Treasury Department has awarded the annual contract for boiler compound to the GEO. W. LORD COMPANY, of Philadelphia. An analysis of feed water for each of the many Government buildings is made several times per year by Lord's laboratory and special chemicals for each case supplied by them. The Geo. W. Lord Co. claims to be the originators of manufacturing boiler compounds in this scientific manner.

THE COMPRESSED AIR MACHINERY COMPANY, of San Francisco, has elected the following officers: P. H. Reardon, President; J. M. O'Brien, Vice President; Eldredge Green, Secretary; Crocker-Woolworth National Bank of San Francisco, Treasurer. The directors of the company are: C. E. Green, Wellington Gregg, Jr., J. M. O'Brien, J. E. Green and P. H. Reardon, who retains the management. The day after the fire they rented various small shops on the outskirts of San Francisco to fill orders for special parts, make patterns, etc. This company had the first building in their line, erected and in operation in the burned district. Their new machines are of the latest type and equipped with individual electric power on each machine. They are now ready to deliver their celebrated Giant Air Compressors and Drills, Word Bros.' Improved Drill Maker and Sharpener, Brownell Engines and Boilers, Shaw's Air-Hammer Rock Drills, Hendrie & Bolthoff Hoists, etc. Their new factory is at the northwest corner of Jessie and Ecker St., between First and Second, Mission and Market streets.

Trade Treatises.

We are in receipt of Catalogue No. 58 of THE MURRAY IRON WORKS Co., of Burlington, Iowa. This catalogue is handsomely finished and covers the engine and boiler field in a most thorough manner.

ALLIS-CHALMERS Co. of Milwaukee, Wis., has issued Bulletin No. 1,052, descriptive of the type B electric generators and motors, made by them, and illustrating this type of motor applied to the operation of a drill-press.

'Unions for Steam Pipes.'—This is an interesting little pamphlet issued by the JOSEPH DIXON CRUCIBLE Co., of Jersey City, N. J., which describes and illustrates various kinds of union couplings used on steam-pipe lines.

Publications Received.

STEAM CONSUMPTION TESTS.—A paper read before the South African Association of Engineers, of Johannesburg, by E. T. Laschinger, A. M. Robinson, and H. C. Behr. It describes in detail the results obtained in a test of hoisting on the Rand at shaft No. 1. of the Village Deep mine, the object being to determine the average rate of steam consumption of a modern high-class, direct steam-driven winding apparatus, under ordinary working conditions, when hoisting ore from a vertical deep-level shaft.

WATER SUPPLY AND IRRIGATION PAPERS, No. 165 and 166 of the United States Geological Survey, being reports on the progress of steam measurements in 1905. Also production during 1905 of precious stones in the United States; of abrasive materials; of monozite, zircon, gadolinite and tantalum minerals, and of tale and soapstone.

TO OBTAIN a private water-supply a deep well is often driven until a sufficient quantity is obtained. As the well is driven, an 8-in. pipe is sunk to form the casing. When the water-pocket has been reached the water will usually rise and stand in the pipe several hundred feet above its bottom, and the amount of water that can be usually pumped from such wells, without lowering the water, is practically unlimited. The cost of drilling deep wells per foot of depth including the casing is, for a well with 8 in. casing, \$4.50 per foot.

Editorial.

THE DISCOVERIES of gold and silver in the Temagami, Teniskaming and Abitibi districts of northern Ontario are extending the boundaries of the mining regions into the great wastes of northern Canada. The most recent find near Lake Opastica, in the adjoining portion of Quebec, is another pointer that way. New Ontario, as this tract is now called, promises to add greatly to the known resources of the Dominion and the day may yet come when the lonely shores of Hudson bay will be enlivened by the miner's activity.

AMONG THE INVESTIGATIONS in progress under the direction of officers of the United States Geological Survey is the completion of the report on Butte by Mr. S. F. Emmons, who will also supervise the examination of the Ely copper deposits. Mr. Charles Palache is making a mineralogical study of the native copper lodes of upper Michigan. Mr. J. M. Boutwell is attending to occurrences of lead and zinc at Joplin, Leadville, the Cœur d'Alene, and Park City. Among the new gold mining districts, Mr. F. L. Ransome will make a geological examination of Manhattan, Goldfield, and Bullfrog, in Nevada.

INVESTIGATION into the origin of tin ores should receive an impetus from the discovery, by Mr. Richard Pearce, of pseudomorphs after one of the sulpho-stannites which occur in Bolivia. Heretofore feldspar and specular iron were the only minerals known to be replaced by cassiterite and the discovery is therefore of importance because it affords evidence of the secondary enrichment of tin ore through the oxidation of tin sulphide and the removal of associated metals. The origin of tin deposits has never been explained with certainty and it is peculiarly appropriate that a mineralogist and metallurgist so long an authority on the subject, should have lighted on this important find.

AN INTERESTING QUESTION of title is suggested by a paragraph in *The Sun*, of Yuma, Arizona, which publishes a statement to the effect that a Mexican discovered some rich mining ground in the northern part of Yuma county, and having an opportunity to sell, did so, receiving part payment in cash. When it was discovered that the locator was not a citizen of the United States, several parties raced to the find to re-locate it. 'Lindley on Mines' says: "We think the following principles have been established by weight of authority: (1) That a location made by an alien, if otherwise valid, creates in him an estate which can be divested only at the instigation of the Government in a proceeding in which it is either directly or indirectly a party. (2) That such estate when vested in a citizen is as complete as if originally acquired by him by location, and no one, not even the Govern-

ment, can assail his title." A location made by an alien is free from attack by anyone save the United States Government. In the Arizona case, therefore, the Mexican might have held onto the claims located by him until 'office-found,' as proceedings in cases of this kind by the Government are called, and the purchaser from the Mexican has good title to the ground in question and may yet oust the jumpers by legal process.

OUR CONTEMPORARY in London, *The Mining Journal*, has added to its staff a consulting engineer to advise on motor transport. This is an interesting sign of the times. While not likely to follow even so good an example, we can state that among the mining engineers resident in our vicinity there are several who could give a good deal of advice on the use of the automobile in mining regions. Most of our leading men have their own cars and in Nevada the automobile is used as much in killing the distances of the desert as the camel in Western Australia only ten years ago. Apart from its convenience in affording quick access to distant mines, the motor car is becoming used for transport of freight and supplies; it is destined to play an important part in the development of the waste places of the earth.

Irish Copper Mining.

The article by Mr. Philip Argall is full of interesting information and it is timely, having in view the fact that copper mining in Ireland has become a success recently. Our London correspondent, in his weekly letter, gives news to this effect. But apart from the opportunity for successful investment, the copper mines of county Wicklow are to be credited for several inventions now widely used. The first patent for wire-rope tramways was granted to Charles Hodgson of Wicklow. It is true, a bas-relief unearthed at Nineveh depicts a rudimentary form of rope-haulage used during the siege of that city over 3,000 years ago, and wooden blocks and ropes constructed of fibres obtained from the date palm, have been found in Egyptian ruins, indicating that rope-haulage was not unknown at an early date. It may be noted also that an old-fashioned print illustrates a fibre-rope with dependent buckets, erected for the city of Dantzic by Adam Wyhe in 1644, and used for carrying earth to the ramparts. Nevertheless, it was not until wire-ropes were made that tramways came within the range of modern engineering. Hodgson received an English patent in 1868, and it is likely that his inventive spirit was stimulated by the energy of the people who worked the Wicklow mines fifty years ago. Another supposedly recent invention originated in these old copper mines. The technical press has lately published descriptions of the mono-rail as used in South Africa, where the device has been introduced successfully. Capt. George Oates, of the Cronebane mine, appears to have been the first to apply the idea to mining and our friends at Johannesburg will be glad to examine the sketches and description contributed by Mr. Argall. Apart from this point of interest, the main subject of precipitating copper from mine-water is deserving of

careful reading by the younger mining engineers, because it affords a good example of the application of chemical knowledge and mechanical ingenuity; although simple, it illustrates the saying that science is a specialized form of common sense.

Progress in Cyanidation.

The comment on current practice at Kalgoorlie by Mr. Alfred James, will interest cyaniders. We also publish a description of a new method of lining tube-mills, as devised by Mr. H. P. Barry, of the great Waihi mine, in New Zealand. One of the practical problems, especially to millmen operating at a distance from manufacturing centres, is the cheapest and most durable lining for the tubes. At first everyone depended upon Iceland pebbles and silex lining from Europe; and to those in charge of mills on the other side of the world—in Australia, New Zealand, and Mexico, for example—it was a serious handicap to depend on supplies from so great a distance. Iron linings of special composition were not much better, for they also were made by methods not available at the ordinary mining town. Both in Mexico and New Zealand the mill-managers have succeeded in breaking away from the tyranny of a special material and they have been able also to procure flints suitable for their purpose. The device invented by Mr. Barry is one of the best improvements in tube-mill practice, and, as it is applicable to other localities, we hope it may prove extremely useful.

In regard to cyanidation generally, Mr. James' remarks are much to the point. The frequent comparisons between the work done by the pans and tube-mills at Kalgoorlie have evidently been of little value as indicating the general applicability of the two machines, simply because the peculiar conditions obtaining at Kalgoorlie have been overlooked. Mr. James sets that matter right. His other criticisms are welcome, and any reply to them will be given a courteous hearing.

It appears likely that tube-mills will be discarded at Kalgoorlie because the tellurides occurring in the ore require roasting; the idea used to be to comminute excessively so as to dissolve these tellurides raw, but now solubility is secured by obtaining the porous condition due to a roast. Filter-presses are already a back number in Western Australia, and elsewhere. Filter machines of the Moore, Butters and other types are displacing the old devices. In fact, cyanide practice is undergoing a continual and rapid development, one device after another being elbowed out of the way to make room for something better. Just now it is manifest that it is cheaper to treat slime by agitation than to treat sand by percolation; it is not only a question of relative cost between re-grinding *plus* slime-treatment on the one hand and percolation of the coarse stuff on the other; the assertive factor is the increase of crushing capacity in the first instance—whether under stamps or between rolls—due to relieving the first crusher of the work of pulverizing. On these subjects we hope to hear from our friends. Experiments are continually under way; the exchange of experience will prove mutually helpful.

By the Way.

IN a recent address to the graduating class at Lehigh University, Dr. R. W. Raymond gave some good advice to the young men about to become engineers. Among other things, he said: As advisers of clients, you will encounter little difficulty in deciding what professional honor requires of you. Yet, now and then, perplexing cases may arise. For instance, you are called upon to estimate the prospects and suggest the best method of exploration of a mineral property owned by your employer. He asks you, not how much money the property is worth, but whether, in your judgment, it is promising enough to warrant the expenditure of money upon it by the actual owner. You make an encouraging report, which he afterward publishes, in whole or in part, to aid the sale of the property or of the stock of a company to which he has transferred it, at a price never considered by you, and beyond your estimate of its present value.

In view of such a possibility, you ought, in the first place, to put into a report of this class no vague, glittering prophecies of future profit, or paragraphs which could be used, without their context, to support sanguine speculative appeals. State clearly, at the beginning of such a report, its purpose and scope. If your employer should subsequently make such use of it as would involve you in propositions you never made or meant to make, protest promptly. Such a protest, to be effectual, should be re-enforced by your own original and carefully guarded statement. Nevertheless, make it anyhow, and make it promptly, if you deem it worth making at all. Post-mortem disclaimers by experts, after the collapse of mining schemes with which their names have been fairly or unfairly connected, have very little effect. You cannot be too careful to make your record absolutely plain, and to protect it, by instant protest and exposure, against even the appearance or suspicion of connivance in delusion or deceit.

Again you may have occasion to appear as expert witnesses in court. Such witnesses are called in cases involving patents, mining titles, the detection of poisons, the details of medical practice, or the value of professional services, etc.

Expert testimony has been, and is, the subject of endless controversy. It is often urged that experts should be appointed by the court, to give advice without favoring either party. This is, in fact, done in criminal cases, where analyses are made for poison; in cases of alleged lunacy, etc.; but I think experience has shown that in ordinary litigation, especially as to patents and mining titles under our laws, justice is best secured by allowing each party to present its own experts, requiring them to submit to cross-examination, and leaving the bench and jury box to pass judgment upon the evidence. The difference between an expert and an ordinary witness is that the former is permitted to give his opinions, however reached, while the latter can give only facts of personal knowledge. The oath of an expert, therefore, binding him to tell "the truth, the whole truth, and nothing but the truth," covers the ordinary obligation as to facts, and also the obligation of the full and truthful statement of expert opinion. Yet there is no doubt that this opinion must be, to some extent, a partisan one. No party to a lawsuit will put an expert on the stand without knowing beforehand that his opinion will be favorable to the contention of his employer. Nor would any such expert be doing his duty, either to the court or to his employer, if he uttered an opinion so carelessly formed or loosely held that he could not vigorously defend it, or would run the least risk of changing it under cross-examination.

The situation is often complicated, critical and exciting. The following suggestions may assist young experts to deal with it:

When such an engagement is offered to you, accept first a retainer for which you undertake to examine the case, form an opinion, and state it to your employer. In a mining case, two such preliminary investigations may be necessary; the first being based upon the *ex parte* case, submitted to you by one side, and the other upon your own personal examination of the facts. After the latter, state clearly to your client the opinion which you are prepared to maintain. If it does not support his contention, he will not wish to put you on the stand as a witness; but you are bound not to assist, either in that case, or (without his permission) in any other, involving the knowledge you have acquired in confidence from him, parties whose interests may be hostile to his.

If you take the stand as an expert, you ought to know already all the facts and authorities which bear upon your opinion. Whatever has been previously adduced in the pending case, you should, of course, have taken into account. What is produced which takes you by surprise, you should not meet with a rash denial or quibble. Your true and wise course is to declare that you are giving your deliberate and careful opinion upon all the facts known to you, and you can not hastily revise that opinion upon new evidence, which you can not, in a moment, test, sift and weigh.

Don't try to be smart or witty under cross-examination. Such an encounter is like a fencing-match in which you have your hands tied. For you are answering under oath, while the inquiries and insinuations of your antagonist are unrestrained. Maintain your opinion manfully but do not even seem to be fighting for your client. Still better: do not fight at all, but assume throughout that the cross-examination attorney is honestly in quest of information, and give it to him with courteous generosity. If you thus give him no opening for insulting comment, he will probably not make any. If he should do so, do not try to protect yourself, but let your counsel or the court protect you. I have seen a witness get the better of a lawyer in repartee and lose the case; and I have seen witnesses browbeaten and embarrassed by clever lawyers, but vindicated by the verdict of the jury, which could not be diverted by mere wit from its search for truth and justice.

THE British South Africa Company reports that the Cape to Cairo Railway has reached Broken Hill. This district must not be confounded with the great silver mining centre in New South Wales, Australia. The African Broken Hill contains large outcropping masses of zinc-lead-silver ore; it is 374 miles north of Victoria Falls, and 2,016 miles from Cape Town, and its connection by rail with the south constitutes a further step toward the fulfilment of Mr. Rhodes' great scheme. The rails reached Kalomo, 93 miles north of the falls, on May 29, 1905, since which date rapid progress has been made. On July 1, 1905, the further extension was begun, and the 281 miles from Kalomo to Broken Hill were constructed in 346 days. On 99 days, however, no plate-laying was done, so that the rails were actually laid at the rate of more than a mile a day. On September 26 last five and three-quarter miles were put in between daylight and dark, constituting a record for rapid plate-laying in South Africa. Three thousand to 5,000 natives were constantly employed, and about 350 whites.

PHILOSOPHY never rests. Its law is progress; a point which was invisible yesterday is its goal today, and will be the starting-post tomorrow.

Special Correspondence.

LONDON, July 11.

The Committee, composed of bankers, business men, a chartered accountant and a barrister-at-law, which was appointed in February, 1905, by the Board of Trade to consider the position of joint-stock enterprise, as affected by the Companies Act of 1900, has issued its report. The Committee points out that the number of companies that invite the public to subscribe has fallen from 11% in 1901 to 8% in 1905, while the companies that do not invite the public to subscribe have increased in the same time from 50 to 76%. Then the total amount of nominal capital shows an enormous and, with one exception, a continuous drop; in 1896 it was £285,000,000; in 1905 it was only £108,000,000. During the same time the average amount of nominal capital to each company fell from £66,000 to £27,000. The Committee thinks the reasons are: (1) War loans have diminished the capital available for investment; (2) the raising of the registration duty by the Finance Act, 1899, from 2s. to 5s. per £100; (3) the stringent provisions of the Companies Act, 1900. It is therefore recommended that a director whose breach of any duty imposed upon him by the Companies Act is the result merely of honest oversight, inadvertence, or error of judgment, shall be removed from liability. "We think, too," says the Committee, "that various recent decisions on the Income-Tax Act, to the effect that a company registered or controlled in England and doing business abroad is liable to be taxed on the whole of its earnings, whether made abroad or in the United Kingdom, and wherever its shareholders may be domiciled, have adversely affected the registration of companies in this country, and have led to their reconstruction so as to place them under colonial or foreign law. These decisions have also to some extent encouraged the formation abroad of companies which might otherwise have been registered here." For the protection of unsecured creditors of a company the balance sheet, the Committee recommends, should be filed with the Registrar.

As anticipated when the Bonmahon Copper Mines Development Syndicate, Ltd., was formed in November, 1905, (noticed in my correspondence on February 6), a considerable amount of money has recently been embarked in Irish copper mining. There was a time when the recovery of copper in Ireland was one of the country's staple industries, but that period is rather remote. The possibilities of the lodes are now being recognized, and not only are English companies interesting themselves in the re-opening of them, but it is reported that American syndicates are also on the point of unwatering mines and commencing production. It is stated that more than one offer has been made to the present proprietors of the Bonmahon lodes for the purchase of the undertaking at a very substantial profit. The Schull Copper Co. is also a concern formed with the moderate capital of £5,250, to work the copper deposits on the island which gives the company its name, but, beyond the fact that the lodes are situated on the mainland opposite to Schull, little information is obtainable. The next property to be taken in hand, it is said, will be the Ballygahan.

The trading carried on by the Niger Company, Ltd., must be of considerable importance, judging from the payment of £106,802 as customs duties in Nigeria for the year 1905. The company reports the acquisition of licenses to mine and the prospecting and mining operations carried on in northern Nigeria have made good progress. Extensive deposits of tin have been shown to exist, but at a long distance from water carriage. When the difficulty of providing efficient land transport shall have been met, it is thought the chief obstacle to rapid development will be removed.

Also situated in the equatorial region of the Dark Continent, the West African Hinterland Consolidated is an instance of unfulfilled promises and expectations. Notwithstanding the favorable reports on the company's properties (which covered an area of 100 square miles), on the strength of which the original working capital of £30,000 was subscribed, no large body of payable ore has been found. Funds have become exhausted, and there seems to be no possibility of obtaining further capital. Little or no financial support

has been rendered by the shareholders, in spite of frequent appeals by the directors for their co-operation, and "with feelings of deep regret" the directors propose to put the company into liquidation. It is to be feared that a like fate will, with effluxion of time, befall other West African development companies which started out to explore large slices of the continent with more enthusiasm than hard cash.

The meeting of shareholders in East Pool and Agar United mines is described by an eye-witness as one of the most enthusiastic ever held on the property, and the 'adventurers' were not only well pleased with the dividend of 12s. 6d., but gratified at the manager's report on the underground workings. During the twelve weeks a profit of £6,497 was made. A proposal put forward by a London-Cornish shareholder to move a resolution instructing the committee to take the necessary steps for the conversion of the mine from a cost-book to a limited liability company was rejected with scorn. Limited company, forsooth! when the adventurers were enjoying the prospect of a distribution among themselves of £4,000 out of profits, bringing up the record of dividends to half a million sterling on a paid-up capital of a few thousands of pounds. Enough to make their great-grandfathers turn in their graves! The audacious Cornish-London shareholder probably returned to 'town' with the reflection that the cost-book system will be good enough for East Pool and other mines while the times are prosperous, but if history should repeat itself with its wonted regularity, and the shareholders get tired of paying calls in search for new 'bunches of tin,' they will have to seek outside help, and such help will only come through the adoption of limited liability.

At the 'ticketing,' or sale by tender last week, 255½ tons of black tin were disposed of at the average price of £102 11s. 5d. The list is useful as an indication of the relative importance of the active mines in Cornwall at the present time:

	Tons.	Amount. £ s. d.
Doleath	72	7,667 2 6
Carn Breu and Tincroft	32	3,016 6 3
Grenville United	31	3,223 5 0
Basset, Limited	28	2,682 5 0
East Pool and Agar United	23	2,369 17 6
Levant	18	1,949 12 6
West Kitty	15	1,614 7 6
Clitters United	11	1,212 15 0
Bottallack	8	788 0 0
Wheal Crofty	8	762 7 6
Burney	3	305 5 0
Portladden	2	202 0 0
Wheal Kitty	1½	153 7 6
Mulberry	1¼	104 1 3
Wheal Bellan	1	106 15 0
Tehidy Tin Streams Syndicate	1	69 5 0
Total		£26,232 12 6

Shareholders in Cosmopolitan Proprietary, Ltd., have met with an experience not uncommon in West Australian mining. This time last year the lode formation had entirely given out in the shaft, in consequence of which the engineers recommended that the shaft should not be sunk further. At that time it was intended to sink a shaft from the drift at a place where the new orebody was cut; but in the course of development and the sinking of the winze below the 11th level a well-defined lode was found to exist, and authority was given to continue the sinking of the main shaft, with the result that the lode formation has been found in the shaft again. At the annual general meeting, the chairman was able to congratulate the shareholders on the fact that, whereas last year they had no indications of the existence of ore below the 11th level, they now know that it continues to the 12th level, and the shaft being down to a depth of 1,732 ft. on the dip, they are in a position to continue the drifts so as to open up a new mine. In the course of his remarks at the meeting, the company's consulting engineer, Mr. C. A. Moreing, said he wished to point out that in Australia—in Western Australia particularly—gold deposits consist of lenses, which die out and re-make. There was a blank space at the bottom of one of their lenses and, in sinking, they had come on to what apparently is another lens. At present that lens is very low-grade ore, but low-grade ore in the Cosmopolitan is valuable, as the working expenses are so low. Mr. Moreing said that when he went through the Cosmopolitan with the manager, that gentleman enthusiastically pointed out patches of ore which, he said, were rich ore. That ore carried less than 6 dwt. of gold, yet he could see a satisfactory profit to the company from working

it, though it was material such as could not be worked at a profit on the Rand, with all its advantages of cheap labor.

A smart rally (owing to bear coverings), took place in Kaffirs yesterday on the record output of June—475,975 oz. gold, as against 461,202 oz. for May. The first crushing of the Cason mine is included for 13,130 ounces.

The approximate figures of the returns for the month of May are to hand from Dolores, Mexico: Ore treated, 982 tons; total receipts, \$39,500; expenses, \$20,000; profit, \$19,500. The report states that the definite milling figures are not yet to hand, but about 600 tons of the above mentioned total were treated by cyanidation, and that the decreased tonnage treated by amalgamation is due to interruptions caused by starting the cyanide plant. Owing to adjustments and experiments incident thereto, the full capacity of the mill was not reached.

TORONTO, July 20.

The Ontario Government has dropped proceedings to invalidate the title of the Nipissing Mining Co., of Cobalt, to its locations, the company having satisfied the Government that it was a bona fide purchaser, without notice of any defect in the title, having paid \$250,000 for the claims. This action has had a reassuring effect, as indicating that where it can be shown that the rights of innocent purchasers are involved, the titles under which mining properties are held will not be disturbed on account of mis-statements or fraud by the original claimants.

Much activity is being shown in providing local smelters for the Cobalt ores. The Montreal Reduction & Smelting Co. has secured a site for the erection of a smelter at North Bay, and is applying to the Temiskaming & Northern Ontario Railway Commission for the construction of a siding to its works. — The North Ontario Reduction & Refining Co., with John I. Davidson as president, and a capital of \$500,000, will build works at Sturgeon Falls for the treatment of both Cobalt and Sudbury ores by the hydro-electric process as applied by the Idaho Reduction Co. at Clarkston, Wash. The plant is to be erected by Holman & Young, owners and partners of the process. Other companies are making application for sites in northern Ontario.

The Temiskaming & Northern Ontario Railway Commission, which has the disposal of mining rights on the Cobalt town-site and the railroad right-of-way, has leased the mining privilege between the 101 and 105th miles on the railroad, embracing the portion lying within the Cobalt area, to the Right of Way Mining Co. The company, which is not yet incorporated, is composed of Ottawa capitalists, including J. P. Dickson, A. W. Fraser, G. P. Murphy and Newton Kerr. The company obtains a 999-year lease and pays a cash bonus of \$50,000 and royalties on the ore mined on a sliding scale, according to value at the mouth of the mine, varying from 10 to 50%. All ore assaying over \$1,000 per ton will pay the latter figure. It is understood that the northwest 40 acres of the Cobalt town-site have been leased on similar terms as to royalties, the cash bonus being fixed at \$22,000.

Dr. W. A. Parks estimates the value of the Cobalt area, including three square miles about Cobalt town, at \$50,000,000. The indications at a depth of 250 ft., he says, point to an inexhaustible supply. [This has been said of every mining camp that ever started.—Editor.] He believes that the mineral territory reaches at least as far as 50 miles north of Cobalt, and anticipates that rich finds will be made in the neighborhood of Lake Abitibi.

In the Manitou gold area, Rainy River district, several American companies are actively at work. The International Mining & Milling Co., the headquarters of which are at Detroit, has been doing extensive development work on its properties at Lower Manitou lake. It has completed a dam for the development of electric power and contracted for mining machinery. — The Golden Rose Mining & Development Co., of Escanaba, Mich., which has over 400 acres of mineral lands in the Manitou area, has struck three or four promising veins near the Twentieth Century gold mine. — The Standard Consolidated Mining Co., George W. Cooper manager, has secured six choice locations and has arranged for the commencement of operations in the neighborhood of the noted Laurentian mine.

BUTTE, July 23.

The Anaconda Copper Mining Co., through an arrangement with the Red Metal Co., will use the shaft of the Belmont mine to work a portion of the Anaconda mine. The Belmont is situated in the southeastern portion of the Butte district, and is surrounded by Anaconda property and underground Anaconda workings. Several years ago the United Copper operators of the Belmont, while developing that mine, broke into workings of the Anaconda at a depth of 900 ft. It is the intention of the Anaconda Co. to make other connections, deepen the Belmont shaft, and at the same time exploit the Belmont for the Red Metal Co. — The Red Metal Co., operating the Minnie Healey mine, has opened a large body of rich ore at a depth of 1,100 ft. The vein was mined under United Copper ownership, but the new owners have opened an orebody 30 ft. wide, seven feet of which averages 7% copper.

The Basin concentrator, owned by La France Co., has been closed temporarily, as it was found impracticable to continue operations after the Red Metal Co. discontinued shipments and sent its ore to the Washoe smelter at Anaconda. The Basin concentrator will not be operated again until the smelter there is equipped to handle the ore from the Davis-Daly Estates mines, and the Lexington mine owned by La France Co. — The shaft of the Ophir mine, at the foot of Dakota street, in the city, has reached a depth of 485 ft. The operators had expected to cut a vein before reaching that depth. A station will be cut at 500 ft., after which sinking will be resumed and continued to 1,000 ft. — The Davis-Daly Estates Co. has decided to sink a shaft on the Silver King claim and another on the Mt. Moriah. On both claims there are small shafts which will be enlarged and sunk to 1,000 or 1,500 ft., the depth to be determined by conditions as the work progresses. Temporary machinery will be used at first and later large permanent hoisting-plants will be installed. — The Parrot Mining Co. is precipitating cement-copper from the tailing dump of the old Parrot works and making a good profit. Up to a few weeks ago lessees were permitted to work on the dump, but it was found that there was sufficient profit in it to justify the company in taking hold of the enterprise. Lessees expended \$30,000 in the precipitating plant, which was taken over by the company at the cost of their investment. — The Boston & Montana Co. is shipping the tailing from the site of its old works at Meaderville to the smelter at Great Falls. It had been lying undisturbed for 14 years, and much of the copper has been leached out and carried away in the waters of the creeks, but the material left still pays the company a good profit in shipping to Great Falls, where it is used for furnace lining, being especially suited for that purpose. — The Butte & London Co., which is developing the Greendale placer claim in the eastern part of the Butte district, has reached a depth of 475 ft. and the bottom of the shaft is in solid rock. A new engine at the shaft is ready for work, but the company is awaiting the arrival of a compressor. Meantime work will continue with the old engine.

The shaft of the Butte Copper Exploration Co., situated just east of the Butte & London mine, is down 730 ft., and at the present rate will reach 1,000 ft. by October. The character of rock has recently been changing in the shaft, the material containing much iron, which is considered to indicate the proximity of an orebody. It is the opinion of many mining men that this portion of the Butte district will develop some good copper mines. The Boston & Montana Co. is opening the Glendale in the same locality. — The Butte & Michigan Co. has installed a new hoisting-engine on its property southeast of Butte, and sinking will be resumed in a few days. The shaft is 100 ft. deep and will be sunk to 500 ft. — The Blue Vein Copper Mining Co., a Butte corporation, has purchased the Soon placer claim, the Valentine and Little Boulder, and a half interest in the Columbia quartz-lode claims, in Butte district. — The directors of the East Butte Copper Mining Co. have elected Frank M. Sullivan president, James A. Talbot vice president, Henry Mueller secretary and treasurer, Patrick Wall general manager, and Chas. R. Leonard counsel. The new plant of the company will be ready for operation within a week. It includes a 16-drill compressor and hoist. The second working shaft, being sunk a quarter of a mile south

of No. 1, has reached a depth of 200 ft., and is the biggest shaft in the district, having four compartments. This shaft will be equipped with a modern head-frame, and the shafts will be connected at every 200-ft. depth. The lessees are taking rich ore from workings above the 200-ft. level, the gross returns amounting to \$2,000 per day, from which the company receives 25% in royalties, which has been sufficient to pay for all improvements, developments and new equipment. The heaviest expense of the company is now at an end, and the expectation is that it will pay dividends soon. Negotiations are also pending for the acquisition of additional property, and a large precipitating plant is being built to treat the tailing from the old Parrot works, which cover a portion of the East Butte Co.'s ground.

F. Augustus Heinze, of the United Copper Co., has purchased a group of low-grade gold mining claims at Rimini, in Lewis and Clark county, and will establish there a big cyaniding plant. He has also bought several large tracts of adjoining ranch-land to be used in connection with his operations. Mr. Heinze is largely increasing his mining interests, having recently purchased properties in Alaska, California, Nevada, and interests in properties in Utah. In the Butte district, however, he is not doing much since the sale of his principal properties to the Butte Coalition Company.

The Great Northern Railway Co. has organized the South Butte Mining Co. to take in all the mineral rights owned by the Hill road in Silver Bow county, mostly included within its rights of way. The South Butte Co. is capitalized for \$50,000, and the incorporators are John G. Williams, M. S. Riley and Arthur Howell, of Duluth, and all connected with the Great Northern railway. It is not the intention of the company to do mining, but it is likely that it will lease the mineral rights to others, or sell them outright. Some rich copper deposits have been found under the railway property. — The Anaconda Co. has begun hoisting ore from the Pacific mine through the Buffalo shaft. — The North Butte Co. is now hoisting 1,000 tons of ore daily. — The old smelter of the United Copper Co., which was acquired by the Butte Coalition Co., is being dismantled. It is understood that several offers were made to Butte Coalition to purchase or lease the plant by independent interests, but the offers were rejected. During the last year of operations by the United Copper Co. the smelter turned out about 3,000,000 lb. copper per month. — A report is current that the Butte Coalition Co. has been negotiating for the purchase or control of the Pittsburgh & Montana Co., but this is denied by the officials of the former.

CALUMET, July 21.

Two important explorations have been inaugurated by the Calumet & Hecla Mining Co. in the last few days. The recently organized Caldwell Copper Co., a subsidiary corporation of the Calumet & Hecla, has started a diamond-drill on its property between the Tecumseh and Rhode Island, where the Kearsarge amygdaloid lode will be explored. The other is northeast of the Mohawk mine, in Keweenaw, where a tract of 240 acres has been acquired, and two shafts started. In this vicinity the Kearsarge amygdaloid bed outcrops for nearly a mile, and a good operating depth can be reached on most of the property. The Calumet & Hecla's new scene of activity is north of the Mohawk's No. 1 shaft, where the latter has been finding its richest ore lately. As the Calumet & Hecla property adjoins the Seneca, which is regarded by some as a promising undeveloped property, the work of exploring the Calumet & Hecla land will help to prove the Seneca. — Construction work on the new engine-house for No. 4 shaft of the Wolverine mine is progressing rapidly. It is built of stone, with a steel roof. The new hoisting engine, to be delivered shortly, will be capable of operating two skips to a depth of 4,400 ft., the limit on the lode in the Wolverine's territory. Now that No. 3 shaft is being used again, it will be called upon to do one-half of the work ordinarily required of No. 4, as considerable repairing will be done in the latter.

Some speculation is being indulged in regarding the properties which the Quincy Mining Co. expects to purchase, a special meeting of the stockholders to ratify the doubling of the capitalization for this purpose having been called. One

report is that the Quincy plans to absorb the Rhode Island, which is closely related to it in its Eastern management; another is to the effect that the land owned by the Arcadian, north of, and adjoining, the Quincy's No. 8 shaft, will be purchased. The acquisition of this land would undoubtedly be of great value to the Quincy; still another report is that it is planned to consolidate with the Hancock Consolidated, but none of these rumors bears the stamp of authenticity. — Sinking in the shaft of the Lake Copper Co. has reached a depth of 500 ft. on the Knowlton amygdaloid belt, where excellent copper ore is being taken out. Diamond-drill exploration continues. It is the plan of the management to obtain a complete cross-section of the entire property. Several lodes have been intersected by the diamond-drill holes, at least one of which is copper bearing.

Work of re-opening the Atlantic shafts is being pushed, as it is desired to resume production as soon as it can be accomplished. In B shaft three crews of men, working eight-hour shifts, are repairing the damage caused by the settling of the hanging wall. There is little damage to the fifteenth level, and further investigation may reveal that below that point the damage has been overestimated. The skip has been operated to the fifth level, the shaft being in first-class condition to that point. It appears that D shaft suffered most from the air-blast. At the third level the passage is blocked, and the drift north of that point shows settled ground for 200 ft. As soon as men can be obtained D shaft will be repaired.

It has been decided by the Allouez management to start another shaft 1,620 ft. north of No. 1 to open the Kearsarge amygdaloid lode. A depth of 90 ft. was reached in the present No. 2 shaft. From the bottom a pipe was driven down 80 ft. through quicksand and water before striking rock, and it is uncertain whether it is the vein at that depth (170 ft.) or one of the large boulders such as have retarded the progress of the shaft. The site selected for No. 2 shaft is 600 ft. nearer No. 1. It will require greater depth to reach the lode, but it will be possible to make connection with No. 1 shaft a year sooner. The Allouez's No. 1 shaft is down 100 ft. below the sixth level. It has been decided to increase the distance between levels from 100 to 125 feet.

DENVER, July 23.

Several weeks ago I mentioned that the heavy snows in the San Juan would probably prove a blessing in disguise, because the spring snowslides would probably uncover some new orebodies, many of the big mines of the district having been found in the freshly plowed path of the avalanche. My prophecy has been most exactly fulfilled by the remarkable discoveries in Poughkeepsie gulch. This gulch or canyon comes into Uncompahgre canyon, about ten miles above Ouray. The precipitous nature of the Uncompahgre canyon is more than continued in Poughkeepsie gulch, and in one place the wagon-road is fastened to the face of the cliff by brackets. The upper part of the gulch consists of an open basin and here there is a pretty lake or two. Just below the open basin, a snowslide cleaned off the surface of one of the giant veins of that country and showed the polished apex of an 8-in. streak of stuff that fairly glistens with free gold. It has since been traced half a mile; the vein, of course, has been known for years and is one of the strong veins of the San Juan region, extending for a known length of upward of three miles. Other discoveries have followed and the width of the ore has been found to be 10 or 15 ft. in places. The 8-in. streak is only the high-grade streak; there is lower grade stuff accompanying it.

Poughkeepsie gulch was mined for silver prior to the panic of 1893 and some of the most picturesque mines in the world are situated on its precipitous sides. I recall one whose tunnel-house is perched on an artificial bench about 300 ft. up the side of a vertical cliff. The cliff extends upward some more hundreds of feet and in order to get a draft for the boilers the smoke-stacks are run up the side of the cliff at least 100 ft. To sample the dump of this mine, one would have to take one's lunch along, for it is a long trip from the mouth of the tunnel to the dump and back.

I don't know how good the old silver mines of Poughkeepsie gulch were, but there was a lot of work done there.

There are two sections of that great mineralized range called the San Juan, which have not been heavy producers heretofore. One was the Poughkeepsie Gulch section and the other is that part which lies above Pagosa Springs. I have heard many reports of discoveries from the latter section lately and it may be no great time till practically every part of the San Juan range will be producing ore.

CRIPPLE CREEK, July 23.

Thirty cars of ore, having an average value of \$40 per ton, have already been shipped from the Knight & Co. lease on the Little Clara claim of the Work property on Raven hill. This ore is being obtained from a stope more than 80 ft. wide, which is being operated through the Ophelia tunnel at a distance of 2,000 ft. from the mouth. A large ore-house has just been erected, which, together with the one already on the property, will facilitate the handling of a much larger tonnage. On block No. 4 of the Morning Glory claim of the above property, Hodges & Talbot, lessees, made their first shipment on July 16 from their new strike on the 150-ft. level. The vein is four feet wide and is expected to give returns of two to three ounces when shipped.

Several of the mines of the district have suffered from the severe rain-storms which have occurred for the last three weeks. The Henry Adney mine on Beacon hill is shut down temporarily owing to the drowning out of the boilers and engine by the flood of Saturday, the 14th. The production of this mine will be in the neighborhood of 250 tons for July if nothing unforeseen happens; the grade of the ore is about two ounces.

The Golden Cycle Mining Co. is said to have acquired 10,000 acres of coal-land east of the city of Colorado Springs, so as to be able to control its own coal supply. A large proportion of the output from this acreage will be used at the Telluride mill at Colorado City, which is being remodeled to handle the Golden Cycle ore.

Several prominent Cripple Creek operators have gone to inspect the new Spaulding district at Ilse, Custer county, which has come into such prominence during the last two weeks. Ilse is situated 25 miles due south of Canon City, being reached from that place by wagon road. The veins, which are in granite, can be followed for a mile or more, and assays ranging from a trace to several ounces in gold per ton have been obtained from prospects, very few of which are over 20 ft. deep at present. Copper and lead have also been found in the veins, but whether in paying quantities or not is yet to be determined.

On the Pharmacist, situated on the east slope of Bull hill, Maxwell, Neville and Carpenter, operating through the Robinson shaft of the Acacia Co., are shipping ore which is giving returns of two ounces in gold per ton. This ore is being obtained at a depth of 180 ft. and is being raised on, at the same time increasing slightly in value, and with no sign of playing out.—The Isabella Gold Mining Co., on Bull hill, has commenced excavating below the big dumps of the Lee shaft for a cyanide-plant that it is proposed to erect. Six 100-ton vats will be installed at first, but the plant will be so arranged as to permit the addition of more vats if necessary. George D. Kilbourne is manager for this company, which will be the first in the district to break away from the mill trust.

The new Henley vein on the Elkton Consolidated Company's property, on Raven hill, has turned out to be a big thing. It is now opened up on the 4th, 5th, 6th, and 7th, levels, the vein being first discovered on the lowest mentioned level. The ore shipped has given returns of from 2 to 10 oz. gold per ton.—The Portland Gold Mining Co. has filed in the United States district court nine separate suits against Stratton's Independence, Ltd., and several of the lessees operating on the Stratton property, for wilful trespass and extraction of ore alleged to belong to the plaintiff company. The amounts mentioned in the suits aggregate about \$360,000. One of the suits is against Stratton's Independence itself and is for \$17,500, the remaining eight being against the lessees, in which the Stratton company is made party defendant. A vertical line was established by W. S. Stratton on the northern boundary of his property separating it from the Portland Co.'s ground, it being agreed between the two companies that ground south of the line should belong

to the Independence and that to the north of the line should belong to the Portland. This was before Stratton sold the Independence to the Venture corporation of London.

The Western Investment Company is making another shipment from its recent strike on the Sacramento, of the Stratton Estate, on Bull hill. This ore is being obtained at a depth of 500 ft., from a vein which is believed to be a continuation of that which is being worked in the Specimen claim adjoining to the north. This same company is also shipping ore from the Orpha May, another of the Stratton Estate properties on Bull hill; stoping is being carried on at the 400-ft. level where the orebody is of good size and of fair grade.

Six inches of high-grade ore has been opened up by Pressler & Co., lessees on the Mary McKinney. Operations are being conducted through the Burch shaft; the seam is very spotty, but the ore broken is two feet wide and gives returns of five to six ounces when shipped.

SALT LAKE, July 21.

The ore and bullion settlements last week aggregated a total of \$513,500. In the Salt Lake Stock & Mining Exchange for the same period there were transfers of 190,927 shares for \$157,035. — The Utah Consolidated Mining Co. is producing copper at the rate of 20,000,000 lb. annually, at a cost, after deducting the gold and silver content, of less than 5c. per lb., equivalent to an annual profit of \$2,500,000. The company began the year, according to the last annual report, with about \$1,500,000 in its treasury. Unless the directors increase the dividends, this would meet all requirements, making it unnecessary to draw on the current year's earnings. There is a possibility of the smelter being removed to another site, owing to litigation over damage from fumes. This is believed to be the reason why the directors did not increase the dividend. The smelter at Murray is handling about 900 tons of ore daily. — The Utah Copper Co. will introduce steam-shovels at its Bingham mines within a week, as the Boston Consolidated has done; these machines will be used for the present in stripping the overburden. Connections have been made with the tracks of the Copper Belt railroad. — The Utah Apex Mining Co., operating at Bingham, has placed \$100,000 of the \$500,000 worth of first mortgage bonds through a Boston brokerage firm. E. R. Hastings, president of the company, stated recently that this allotment would give the company sufficient funds to carry out its proposed plans of development and equipment. If a smelting plant is built later, however, the remainder may be offered.

The City Rocks Mining Co., at Alta (R. P. Edwards of Salt Lake, manager), is installing an aerial tramway to connect the mine with the tramway system of the Continental Alta Mines & Smelters Corporation over which ore will be transported five miles for 40c. per ton. It will then cost \$2.25 per ton to get ore to the smelter.—The Interstate Mining & Milling Co. has been formed with \$100,000 capital stock, to operate in the Silver Lake district, Utah county. G. B. Kelly, of Salt Lake, is president.—The smelter of the Glasgow & Western Exploration Co., situated at Golconda, Nevada, is to be overhauled and equipped with devices invented by Otto Stahlman, the general manager. Machinery has been ordered from Chicago. The headquarters of the company are in the McCornick block, Salt Lake.

Last week ore shipments from Tintic district, in Juab county, aggregated 105 carloads, the shippers and their contributions being: Centennial-Eureka, 6; Carisa, 4; Ajax, 3; Black Jack, 8; Beck Tunnel, 8; Grand Central, 6; Gemini, 5; Eureka Hill, 4; Eagle & Blue Bell, 7; Dragon Iron, 13; Uncle Sam, 2; Victoria, 3; Yankee Con., 4; Scranton, 4; Ridge & Valley, 3; Mammoth, 9; May Day, 2; other mines, 2.—The directors of the Lower Mammoth Mining Co., at their next meeting, are expected to levy a five-cent assessment, and the shaft will probably be ordered sunk 300 ft. The mine is in debt about \$19,000.—Work is progressing on the new compressor plant of the Yankee Consolidated Mining Co., at Homansville, which will replace the one destroyed by fire.—Another 12-ft. body of lead ore, of shipping grade, has been encountered in a raise in the Eldorado claim of the Scranton Mining Co.

Park City ore shipments this week aggregated 2,041 tons, the contributing mines and respective amounts being: Daly-Judge, 675; Silver King, 621; Daly-West, 495; Kearns-Keith, 56; Little Bell, 127; New York, 32; Moore Con., 21; Jupiter, 12.—The property of the Odin Mining Co. continues to improve with development, and shipments will probably soon commence.—The property of the Steamboat Mining Co. recently passed to the control of Jesse Knight, of Provo, Utah, who is working 15 men. The mine is being opened by adit. William Witt, of Heber City, Utah, is superintendent.—New York Bonanza shipments will be resumed next week and officers of the company say they believe the shareholders will not be called on for another assessment for some time.—At the Magnolia-St. Louis, pending the installation of pumps, the sinking of the shaft has been discontinued.

CANANEA, Mexico, July 24.

Details of the deal whereby the America mine has changed hands were made public last Saturday. Beside this mine the property of the Cananea-Duluth Mining Co. was also taken over. The purchase price of the America is announced as being \$2,500,000 and that of the Cananea-Duluth \$500,000. The basis upon which the sales were made is that one-third of the properties will be owned by Col. W. C. Greene, president of the Greene Consolidated Copper Co., and the balance owned by Thos. F. Cole and his associates. The America property was held under bond by, Lewisohn Bros., of New York, and this bond expired last April. When Lewisohn Bros. endeavored to have the bond renewed, they found that it had been tied up by Col. Greene and his associates. These properties will be handled by a new company which will be known as the Cananea Central Mines Co. to be capitalized at \$10,000,000. The entry into Mexican mining fields by the powerful interests that Cole and associates represent is looked upon as an event of great importance, as it means that the production of this camp will be greatly increased.

The Greene Gold-Silver Co. is installing dredges at its La Brisca property. These dredges are about 385 ft. long and each dredge carries its own amalgamating apparatus. The dirt that will be handled assays \$2 per ton and the dredges have a capacity of between 2,000 and 2,500 tons per day. The Greene smelter at Guaymas will be completed in a very short time. Owing to increasing the size of the plant, it is necessary to erect another stack, and this is what is holding the plant back. The smelter will have a capacity of 500 tons per day.

The West Cananea Copper Co. was organized last week to develop a number of claims lying five miles west of Cananea. On the property there is a copper outcrop 600 ft. long and from 40 to 60 ft. wide, which gives assays from 2 to 4% copper anywhere on the surface. An adit has been driven into the hill, which has already cut the vein at about 45 ft. from the surface. The ore in the breast assays 20% copper and \$6 in gold and silver per ton.

The Santa Beatriz Mining Co., controlled and owned by the Santa Beatriz syndicate of London, England, is doing a great deal of work on its property on Cocospera mountain, in the Magdalena district of Sonora. The mines are on the south side of a highly mineralized copper hill, and on the north side there is over 5,000 ft. of work done which is over 100 years old. Both the *antigua* and the present workings are in ore which assays over 45% copper on the average. It is one of the richest copper deposits in the State of Sonora, and with a little more work can be mined at a great profit.—Ore assaying 26 oz. silver and 17% copper has been encountered in the breast of the adit being run on the property of the Cananea Eastern Mining Co., which is situated about 13 miles east of Cananea. This strike was not expected, as the main vein was not within 105 ft. of the end of the adit which was being run to cut it. From present indications it is expected that the strike will develop into an orebody of considerable size, and that when the main vein is cut the property will become a good producer.—The installation of the new pump at the Campana shaft of the Sierra de Cobre mine has done away with all trouble from water. This mine, which is owned by the Copper Queen Co., is shipping 200 tons of 5% copper ore daily, to the Douglas smelters.

Mining Summary.

ARIZONA.

COCHISE COUNTY.

(Special Correspondence).—At the Calumet & Arizona, one of the furnaces is now completed and should be in operation by the first of next week, when the output of that smelter will be increased 15%.—At the Copper Queen smelter the principal improvement is the addition to the steel smoke-stack, which will be made in one piece and placed in position by means of scaffolding. The first of the new furnaces at this smelter will be ready for operation in September.—In the Lake Superior & Pittsburg property two new orebodies have been found. At the shaft the foundation is being built for the new hoist, which will be a duplicate of that at the Junction. At the Hoatson shaft the pump-station has been completed on the 1,150 level, and the pump will be installed during the coming week. On this level driving is in progress with no increase in the flow of water, which is 100 gal. per min. Sinking will be resumed August 1.—At the Holbrook shaft of the Copper Queen there has been trouble this week caused by the settling of the ground. The shaft-timbers were squeezed so that they interfered with the work of hoisting. This is now being remedied.—At the Shattuck they are getting ready for shipping ore. The new tramway will probably be ready for use August 1. The new steel head-frame is now on the ground and will be erected early in August. The new hoist is expected to arrive next week. At the Denn-Arizona they are still driving toward the diamond-drill hole on the 1,000-ft. level, and at present are working in iron ore, which was encountered two weeks ago, 40 ft. of drift having failed to show the end of it. Sinking was resumed in the shaft Friday, and it is to be continued to 1,200 ft. The flow of water is 350 gal. per min. The new Prescott pumps will be installed in August.—At the Cochise, the shaft is down 600 ft.; most of the drifting being done on the 300 level. A new exhaust-fan has been installed on the 300. The new 150-h.p. boiler will probably be in use at the beginning of the week. Development now indicates that the main orebody is north instead of south of the shaft as was formerly thought.

Bisbee, July 21.

(Special Correspondence).—The Elwell Mining Co., operating the Exposed Reef mines in the Huachuca mountains near Palmerlee, contemplates crushing its ore dry to 20 mesh with rolls, concentrating on Wilfley tables and cyaniding the sand. G. R. Wellborn is superintendent.—A Montana company has taken over mines near Palmerlee and is building a road over which to haul a large compressor.

Palmerlee, July 21.

YAVAPAI COUNTY.

(Special Correspondence).—Active operations on the Rainbow Mining Co.'s properties in the Bradshaw mountains have been suspended during the absence of W. E. Paul, general manager in the East. Upon his return he intends to install a reduction plant at the mine. One of the veins is opened by an adit 344 ft. long, which connects with a 135-ft. shaft sunk on the vein from its apex. In the adit the ore is continuous, with a width of two to six feet, while the pay-streak in the shaft averages three feet in width. The ore in shaft and adit samples over \$30 per ton gold, silver, and copper. Farther north, along the same vein, another adit has been run, in which the pay-streak is eight inches wide with the same general average value as in the other. It is thought that the ore of the higher levels has not yet been struck in the lower workings. The group consists of nine patented claims, which includes timber and water rights. The camp is two miles from Crown King, the present terminus of the Bradshaw mountain railroad.

Prescott, July 21.

It is reported at Prescott that the parties working the Copper Hill property, in Copper basin, have cross-cut 30 ft. of ore which carries \$30 per ton in copper and gold.—It is reported at Congress that the Sayer mine, near that place, is to be re-opened. The vein is large and the ore free milling.—Sinking is to be resumed on the Coronado mine.

CALIFORNIA.

AMADOR COUNTY.

James Cosgrove recently found a good-sized diamond while panning a clean-up on his property, the Matt White gravel mine, near Volcano. A number of diamonds, all of them small, have been found in the ancient gravel channels at Volcano and at Rancheria, though no systematic search has ever been made for these gems.—A new pipe-line is being laid from the reservoir to the Kennedy mine, near Jackson, to supply the works with water. Permission has been given to connect a four-inch main for fire purposes.—The Bay State mine, four miles north of Plymouth, has resumed operations, under the management of stockholders and others. For 15 years development has been vigorously prosecuted except at short intervals. The property has had a varied career, at times looking well and producing good ore, but this condition was spasmodic, at best; it has now been determined to give it another trial.

CALAVERAS COUNTY.

It is reported that capitalists are negotiating for the purchase of the copper mines near Campo Seco—the Harmon, Borger and other claims—which are to be consolidated under one management.

DEL NORTE COUNTY.

(Special Correspondence).—Mining history is being made rapidly in the Del Norte district, and interest in mines and mining matters is becoming general. Those interested in mines are making an effort to develop them, and a feeling of confidence seems to prevail. Mr. Marlowe has a crew working on the Doctor Rock, a copper property, on the headwaters of the South Fork of Smith river, and Dr. Heintz, of Redding, is carrying on a like operation on Rogue river.—J. N. Britten has men working day and night driving an adit to cut the vein on the Hard Luck claim on Sheely creek, recently purchased from Mrs. E. Graham.—While prospecting on the Monumental property last week, G. F. Morgan and Louis Graham discovered a 30-ft. vein of ore similar to that found on the 40-ft. level of the main shaft. The vein is exposed for 600 ft. standing as high as 40 ft. above the surrounding country.

Crescent City, July 23.

EL DORADO COUNTY.

(Special Correspondence).—At the Sherman mine, near Placerville, where 12 men are employed prospecting, they have struck good ore in the 300-ft. level.—At the River Hill mine, near Placerville, the main shaft is 1,300 ft. deep. The vein is 30 ft. wide, about 20 ft. being good milling ore, the greater part of which is coming from stopes above the 1,150. A 20-stamp mill, run by water-power, is on the property. The water, with a fall of 220 ft. at the mill, develops 35 h.p. whence it is piped to the lower compressor where, under 600-ft. head, it develops 150 h.p., furnishing compressed air to run drills and to operate the entire plant. The shaft will be sunk 500 ft. deeper. Fifty-five men are employed. Thos. Clark is general manager and G. M. Clark is superintendent.

A body of rich ore is reported discovered on the 1,000-ft. level of the Mt. Pleasant mine at Grizzly Flat. This mine has produced some rich gold ore in the past, and a great deal that is low grade. It had been idle for some time until recently.

SAN BERNARDINO COUNTY.

Charles M. Schwab, B. Gillies, H. Ramsey, C. E. Knox and J. Salsberry are reported to have bought 17 claims from Arthur Kunz at the Greenwater copper camp 50 miles southwest of Rhyolite. Ore running 40% copper is piled on the dump awaiting the coming of the 'Borax Smith' railroad, which will pass 12 miles from the camp.

The Arizona-Mexican Mining & Smelting Co. has completed the purchase of 3,000 tons of lead ore from the Humboldt smelter, near Mayer, Ariz., which had been buying lead ore for several months but found itself entirely occupied with copper ore, and sold its accumulation of lead ore to the smelter at Needles. The shipments will continue at the rate of two or three cars per day until the entire amount has been received. The Needles smelter is now the only lead market between El Paso, Texas, and San Francisco. The roasters were started last week and are working steadily now,

treating 40 tons per day.—W. H. Smith, of Vanderbilt, has bonded the Desert Queen group, belonging to Green, French and Wallace, and situated eight miles northeast of Blackburn siding, on the Santa Fe, south of Manvel. On these claims is a porphyry dike 130 ft. wide, in which are quartz stringers assaying, it is said, from \$400 to \$500 per ton. The porphyry and tale between the seams prospect in free gold; there is also silver and lead.—The Raven Co. has paid \$15,000 to W. L. Williams for his property. The same company has also bought property from T. Cunningham, for which it paid \$8,000; Hanson brothers have purchased the Amargosa mines for \$120,000; and Chisholm & Co., of Los Angeles, are negotiating a deal with Boston parties for the purchase of the Riggs silver mine, known as the Alta group.—William Wheaton has discovered gold in San Antonio canyon, seven miles from Upland. For years Wheaton has been prospecting in the San Gabriel mountains, but up to a week ago accomplished little in the way of discoveries. He now is reported to have discovered, at Spring hill, ore which assays from \$150 to \$300 per ton. The firm operating the mine is known as the Wheaton-Morgan Mining Co., with William Wheaton and John Morgan as chief owners. At present the ore is being packed to the trail on burros and thence by wagon to the railroad.

SHASTA COUNTY.

It is reported that the Friday-Lowdon group of copper mines near Kennett has been bonded by the Mammoth Copper Co. for 18 months, in the sum of \$200,000. The mines are owned by J. R. Lowdon, of Redding, W. Friday, of Kennett, and T. Hart Benton, of Shingletown. Mr. Lowdon and Mr. Friday have owned the group for 12 years and have spent \$25,000 in development.—The Mountain Copper Co. has miners in the Hornet taking out a run of 200 tons of ore. The Hornet is about two miles from the Iron Mountain mine. It contains a larger body of ore than the Iron Mountain, but it is of lower grade and of a different character. The Mountain Copper Co. has long contemplated working ore from the Hornet, and the results obtained from this test will largely determine future operations.—At the Bullychoop mine, on Bullychoop mountain, 200 men are employed and the 10-stamp mill is in operation. The roads that have been building for several months are nearly completed, and when finished the machinery for an electric power plant, on Indian Creek, will be hauled in. It will furnish power to run a large compressor to be installed at adit No. 3. An aerial tramway will connect the mill and mine. A 30-stamp mill is also to be built.

SISKIYOU COUNTY.

Four men are stoping and sinking in the Highland mine, situated in the western part of the county, and owned by J. Tetherow.—Hathaway brothers and Munger have a camp at Cold Spring and are prospecting in that vicinity.—A Los Angeles company has made a second payment on the Hardscrabble group to R. Pitcher and J. Bingamen.—Burton & De Nure, of Quartz valley, are stoping and their new mill is running. The placer mines owned by Wright & Fletcher, and the Eastlick mines, are still operating their giants and elevators at Oro Fino. They have an abundance of water and it looks as if they would have plenty to run them until August 1.—The wire and poles for the new electric power line of the Morrison mine, at Quartz valley, have been placed in position, and connection will soon be made with the Siskiyou Power Co.'s line. It is the intention to sink on the ore about 200 ft. Huey and sons' mine, joining the Classic Hill, has reached pay-ore. Mr. Huey had his left leg broken by a piece of falling roof while taking out a pocket of gold.—One hundred and thirty mining locations were filed in the county recorder's office in June. The big increase is largely accounted for by the copper excitement in several districts.

TULUMNE COUNTY.

The Harvard Mining Co. now employs 45 men at its mine on Whiskey hill, near Jamestown.—At the Granite Hill Mining Co.'s property, the Densmore mine, near the Stanislaus river two miles north of Columbia, 22 men are employed. A. J. Crowell, the manager, says that when the

air compressor arrives at the mine, machine-drills will be put in. The 10-stamp mill is running steadily.—A steam-hoist is being set up at the Imperial group of mines, below the Shawmut, near Chinese. Sinking will be resumed.—C. A. Fitzgerald, William McGinn and A. F. Davis have bonded to J. G. Davies and R. A. McWilliams the Patterson mine and mill-site and the Lennan mine, situated near Tuttletown. The conditions of the bond give Davies and McWilliams three and one-half years in which to make payments aggregating \$30,000, the deed to remain in escrow. They are to make the first payment of \$10,000 on December 6, 1907. Work must be commenced within 30 days and continue with at least four men during the life of the agreement. The crushing of rock must begin within a year and 25% of the gross proceeds be given the owners.

(Special Correspondence).—Either the demand for miners is much greater or the number available is less at present than usual, as few of those willing to work are out of employment. Until recently employers have experienced little difficulty in securing all the underground laborers desired. The most important of the recent transactions in this county is the sale of the Dead Horse mine and the Lady Washington property at Carters, which were deeded to C. Y. De Lay, by the Eureka Con. Gold Mining Co., of which E. J. McCutcheon is president. According to reports the Grizzly, New Albany, Dead Horse and Lady Washington will be consolidated.—Colorado people have been examining the Bourbon mine, near Tuolumne. Development shows a large vein of good ore. Ten men are employed.—The New Lead mine, situated near Phoenix lake, three miles east of Sonora, has been bonded to L. K. Brown, of Los Angeles, and Truman Sherick, of Salt Lake City.—The force at the Eagle-Shawmut, near Jacksonville, has been increased. Operations are to be resumed at the Atlas mine on Jackass hill, near Tuttletown. The mine is being unwatered.

Tuolumne, July 17.

(Special Correspondence).—The supply of water for mining purposes will last considerably longer this season than usual, adding materially to the prosperity of the county. The rivers are higher now than they have been at this time of year for twenty years, and it is probable that the mines depending on water for power will not be forced into idleness.—The Standard Gold Mining Co., developing several claims in the Buchanan district, expects to soon have its mill ready for crushing ore from the Paymaster. An air compressor and rock-crusher are now being installed.—Two hundred men are employed at the Eagle-Shawmut at Jacksonville, and the mill and chlorination works are in operation night and day.—The pay-roll of the Grizzly has been increased. The Paymaster and Hardtack mines are also working with augmented forces.—In running an raise from the 500-ft. level in the Spring Gulch mine ore of unusual richness was found this week. The vein is four feet wide and the rock is thickly speckled with gold. The shoot is 100 ft. long and no stoping has been done between the 500 and the 400 levels. The mill is running steadily and nine men are employed.—Wm. Sharwood has agreed to sell a mine near Soulsbyville to the Bagdad-Chase Mining Co., which is operating the Soulsby.

Tuolumne, July 24.

COLORADO.

BOULDER COUNTY.

(Special Correspondence).—Walter & Row are installing a hoisting plant on the Golden Queen, and are ready to cut ore. The shaft is down 85 ft. There is gold and copper in the ore, some of which they shipped while sinking the shaft.—The stockholders of the Myrtle Mining Co., operating the San Blas, will meet here in a few days, when they will decide whether the mill is to be rebuilt. It had just been put in shape to operate when it was burned. A. T. Rautenberg is manager.—George M. Mitchell, manager of the Ward-Struggler Gold Mining Co., is driving a cross-cut at the 500-ft. level. The main Struggler vein was cut at 130 ft. after starting the cross-cut. The mill on the property is idle. The ore is complex, and it will probably be necessary to make some changes in the mill to effect a close saving. Frank W. Smith is superintendent.—W. F. De Camp, of Denver, is operating the Humboldt mine and

treating 30 tons per day in the 15-stamp mill, besides shipping ore. G. A. Kline is superintendent.—A good strike has been made in the Sullivan mine under lease to Nichols, Jones and Zoller. The ore carries gold, silver and copper. They expect to ship a car per week. Machine-drills are being considered. The vein is six feet wide.—The Upper Utica, under the management of John McNery, is making regular shipments to the Quiglyville mill.

Ward, July 19.

(Special Correspondence).—B. K. Stambaugh, superintendent of the Parallel, is sinking and driving. The shaft is down 118 ft.—Several lessees are at work on the St. Joe, taking out a good grade of ore. C. F. Cross is in charge.—The Pollock Mining & Milling Co. installed a concentrating mill last year, but, owing to scarcity of water, it has been unable to run regularly. Many radical changes were made in the mill from the original construction. There are 5,000 ft. of workings on the vein. The two adits are each 900 ft. long. Report says 30,000 tons of ore are blocked out in the mine which will average \$10 to \$12 per ton. It is sulphide of lead, iron and zinc. The mill treats 40 tons per day, concentrating six tons into one, the concentrate averaging \$50 per ton. The ore passes over a grizzly at the mine, where the shipping ore is taken out by hand and the mill dirt sent to mill by a gravity tramway. The plant is 1½ miles from a railroad. L. A. Newell is manager, and R. P. Apollonie superintendent.—Merrick & Straub are starting an adit to tap the Commonwealth, Cashier and other veins on Big Horn mountain near Summerville. They are also installing a compressor.

Salina, July 19.

CLEAR CREEK COUNTY.

The Democrat Mountain Mining Co., operating near Georgetown, has decided upon the erection of a concentrating mill at its Moline mine with a capacity of 50 tons per day. The mill will be on the same plan as that at the Mendota. An aerial tramway is to be erected 2,000 ft. long, from the Moline adit to the mill, which will be built near the mouth of the Kelly adit. A 2½-inch pipe-line has been laid from the power-house to the Moline to convey compressed air for machine-drills which will be put in a raise.

DENVER COUNTY.

A new smelter, planned principally for handling ore carrying zinc, which is rejected by many smelters in the State, will begin business August 1 in Denver.—The Wallace Ore Reduction & Sampling Co., organized a few days ago, has purchased the Hitchcock woolen mills in South Denver, and will install machinery for handling ore, and by August 1 will be ready for business. It is the plan of the incorporators to handle but 25 tons of ore daily at the start, and they have already contracted for ore far ahead of their capacity. When the new sampler was first planned offers were made from mine-owners all over the State to supply the smelter with a great quantity of ore, ten times the capacity being offered, even before the incorporation was announced. Enough ore has been contracted to insure the success of the enterprise. Contracts for ore from Breckenridge, Leadville, and other camps, where much of the ore carries a large quantity of zinc, have been signed.

LAKE COUNTY.

Emil Ludwig has resumed work in the By-by group in the Red Mountain district.—The Mammoth mine in Lincoln gulch, near Twin Lakes, is again in operation.—The Ruby Mines Co. is getting out shipping ore. At the Doctor mine, near Twin Lakes, gray copper carrying wire silver is being mined.

SUMMIT COUNTY.

(Special Correspondence).—The mining outlook at Breckenridge is unusually good. The district generally, and Breckenridge in particular, has not looked so well for ten years. The resuscitation of old properties, now being worked for zinc, and the introduction of scientific methods in handling low-grade ore, are bringing Summit county to a position it should have occupied long ago.—The Wellington mine management is outlining a program of extensive development and the installation of new machinery.—The Wire Patch mill is near completion and will be in operation by August 1.—The Old Union Co. has resumed milling

after installing new screens. This company ships 10 carloads of high-grade concentrate per week.—The Atlantic Mining Co., owning extensive property on North Star mountain, has completed a series of tests in ore treatment. The company leased the stamp-mill in Montgomery camp at the foot of Hoosier pass, put the mill in order and several runs were made under the supervision of Frank Lawrence. The runs were satisfactory, and the company has decided to build a mill of its own and put in an aerial tramway. This company has a group of 37 claims, and some of the ore runs 15 oz. gold per ton. The ore is talcose, and shipments to smelters contain 20 to 30% moisture. It is expected that by milling, and perhaps cyanidation of tailing, the excessive charges will be eliminated.—The Puzzle mine is to be operated under new management. James F. Callbreath has made a consolidation of the Puzzle and the Gold Dust mines, and is arranging to work the properties jointly. Electric power will be installed and the Puzzle workings unwatered. The Puzzle contains high-grade silver-lead ore and also an immense tonnage of concentrating ore.—H. T. Koltie, of Joliet, Illinois, president of the Washington Joliet Mining & Milling Co., is in Breckenridge inspecting the company's interests.—The Truax-Tecumseh claims on Mineral mill, above French gulch, have been leased to local operators. The old workings will be cleaned out, and the large zinc-bearing veins will be opened up. This property was abandoned years ago on account of the high zinc content of the ore.—The Wellington, Country Boy, Old Union, Morning Star, Lucky, Minnie, Bullion King, Gold Dust, Pennsylvania and Liberty are all shipping regularly. Breckenridge, July 21.

SAN MIGUEL COUNTY.

(Special Correspondence).—The Japan-Flora Mines & Tunnel Co., of Denver—owning the Japan, Flora, Mikado, Ajax and Valley View mines, at Smuggler—resumed work last month. F. C. Bowman is superintendent. The old Japan concentrating mill, situated at the upper workings of the property, is being repaired to treat 25,000 tons of ore blocked out above the mill-level. The development of the lower workings of the Japan and Flora veins will be continued through the new 2,700-ft. cross-cut adit, and development of the Ajax group, which is the southeast extension of the Smuggler-Union vein, will also be pushed.—Temple-Ingersoll electric air-drills having been installed for that purpose. The company has purchased a five-acre mill-site on the railroad at Pandora, adjoining the Smuggler-Union mill, where eventually will be erected a large concentrating plant, when the orebodies in the various groups are sufficiently developed. At present 100,000 tons of ore are blocked out. This property recently changed hands. It was formerly controlled by T. Walter Beam, A. J. Clark and David Swickhimer, of Denver, who sold their holdings at a valuation of \$600,000 for the entire property. The present directors of the property are: J. J. Fisher, Pittsburg, Pa., president; A. G. Brownlee, Idaho Springs, vice president and manager; J. P. H. Cunningham, Newcastle, Pa., treasurer; Chas. H. Johnson, Newcastle, Pa.; and Wm. H. Shinn, Carnegie, Pa. Wm. E. Humphreys, of Denver, is secretary of the company.

Smuggler, July 21.

IDAHO.

BLAINE COUNTY.

The second-class ore accumulated at the Idaho Democrat mines of the Della Mountain Mining Co. the past year, at Hailey, is being concentrated by hand-jigging.—The concentrator for the Dollarhide mill has arrived and milling will be resumed in a few days.

SHOSHONE COUNTY.

A strike is reported in the Black Horse mine, near Murray, owned by the Idaho-Montana Summit Co. In the west drift on the lower level, two feet of clean galena has been opened. The property is under bond to the Federal Co.—Jerome Day has bonded the Pilot mine, where a rich gold strike was made recently.—The Idaho-Montana Co., which made a strike on its property late last fall, has just started work for the season. The group consists of 10 claims on the Idaho-Montana divide, five miles above Burke on the Glidden road. The discovery made last fall consisted of 18 in. of galena on the surface. An eight-foot

shaft, since sunk on the showing, has opened three and one-half feet of quartz and galena, the latter occurring in streaks two to four inches in width. All of the quartz is impregnated with galena. The presidency of the company will be taken by R. H. Pascoe, superintendent of the Standard-Mammoth mines of the Federal Co., on his return from Europe.

MONTANA.

JEFFERSON COUNTY.

Clarence Rae has made a bond and lease of the Iron Parrott and Little Kid, belonging to Warren Snodgrass, and a steam-hoist will be put in. He has also disposed of the Copper King and New Albany in the Amazon district. A boiler and hoist will be put in and a shaft will be sunk 200 ft. Ore on the Little Kid assays \$100 per ton and will be shipped, as it pays from the grass roots.—The Michigan-Montana Mining Co., operating the Blue Bird mine, near Wickes, is now encountering rich veins in the 1,800-ft. adit, and the superintendent will drive 400 ft. more to tap the main ore-shoot in the old shaft. Several companies are now mining in the Wickes district.—Mr. Bird, of the Beaver-town section, is exploring his claim with a diamond-drill and has crossed one of the several veins. He is working 15 men on three shifts.—The Scotia is now making regular shipments of eight tons per day to Bingham, Utah. The vein is two to three feet wide and the ore assays \$45 to \$110 per ton gold and silver, with an excellent showing of copper and lead. Dever & Ackley have a bond and lease on this property from Dan McNeill.

SILVER BOW COUNTY.

The mills of the Montana Zinc Co., at Butte, were destroyed by fire on July 20. The plant was in the old silver mill of the Alice Mining Co., the oldest mill of the kind in the State.

NEVADA.

LINCOLN COUNTY.

(Special Correspondence).—A few facts concerning this camp may be of interest. Searchlight has 1,500 inhabitants; 700 men are employed in the mines; the altitude is 3,800 ft.; the climate permits outside work the year round; there is a cheap and abundant water supply; a good ice plant, excellent hotels; an electric light and power plant is being completed; a railroad is now within a few miles of the camp and coming nearer every day. There are over 40 active mines, of which the following are equipped with stamp-mills: Quartette Mining Co., 20 stamps (adding 20), Cyrus Noble Mining Co., Duplex Mining Co., Searchlight Mining & Milling Co., Southern Nevada Mining Co., New Era Mining Co., Black Hawk Mining Co. and Techaticup Mining Co., each 10 stamps and Chiquita Con. Mining Co., five stamps. 'Wildecutting' is not successful in this district, as it requires a great deal of money to reach the large bodies of pay ore; in fact, it is generally necessary here, to go to water-level—200 to 300 ft.—at an expense of at least \$10 per foot, which would exhaust the treasury of a cheap concern two or three times over. Success has, however, thus far been the reward of every property that has reached that depth.—M. L. Tobin, superintendent of the Chiquita Con. Mining Co., reports activity in the Juniper section of this district. Although there is a mill with cyaniding plant at the Blackbird mine, of this company, the ore is being shipped to the Needles smelter to minimize the loss in treatment. The shaft is 85 ft. deep and drifts have been started. The vein averages 18 in. wide. The whim is to be replaced by a 50-h.p. hoist.—A new company has been incorporated at Nob Hill, under the name of the Eldorado Sphinx, to take over the property of an old mine worked and deserted 40 years ago. The workings consist of an adit 160 ft., a winze 40 ft., and a raise to the surface from the adit. The ore, iron sulphide, carries \$20 gold per ton, some of it containing 15% galena which assays 480 oz. silver. A 20-h.p. hoist has been ordered.—The Barnwell & Searchlight Railroad has established a shipping station nine miles this side of Barnwell and 12 miles from Searchlight. The hardest part of the grading has been accomplished, and as the level plain between the nine-mile point and this camp offers practically no obstacles to construction, the ticket-stamp will soon be working in Searchlight.

Searchlight, July 21.

NYE COUNTY.

(Special Correspondence).—The Manhattan Dexter Mining Co. has in contemplation the erection of a stamp-mill, but has held back awaiting the development of water, which is to be piped from East Manhattan. It does not have to wait longer, for at the bottom of the shaft on Lease No. 14 of its Union No. 9 claim, water in abundance has been encountered. The lessees have been blocking out the ore, and a short time ago at 190 ft. struck a large flow of water, and it is believed enough can be obtained to supply the mill continuously.—The Raycraft lease on the Little Gray, it is claimed, has enough ore blocked out to keep a 20-stamp mill running two years. The largest vein is 8 to 12 ft. wide.—A stringer of rich ore was reported cut in the Mustang Extension a few days ago, and free-gold specimens have been taken out. This vein is about one foot wide.—The adit on the Gregory group of the Manhattan Nevada Gold Mines Co., at Central, is now in 95 ft. A vein 10 ft. wide has been cut and the ore assays \$10 to \$12 per ton gold.—The adit will be continued through the hill to intersect all veins traversing the company's holdings.—Gold ore is reported found on the Monday claim of the Original Manhattan Mines Co., situated half a mile north of Central. The ore is being sacked, and a shipment will be made within a few days. The vein is three feet wide.—The Manhattan Butler Mining Co. has recently been incorporated and is now developing its claims at North Manhattan, five miles from Manhattan. Two adits are being driven and good ore is being found.—An eight-foot vein has been uncovered on the St. George claim of the Manhattan-Whale Mining Co., this being the third property that has uncovered this large vein of sulphide ore which trends east-west through Gold Hill. The Bullhead claim of the Manhattan Gold Crater Mining Co. encountered it at a depth of 75 ft. and the Cowboy Mining Co. at 60 ft. These properties are blocking out ore and hunting for a rich pay-shoot in the large vein.—The hoist for the April Fool claim of the Seyler-Humphrey Gold Mining Co. has arrived and is in place. Adjoining this is the property of the Manhattan Standard Gold Mining Co., which is installing a gasoline hoist.—The Manhattan Consolidated, and Consolidated Extension, are working to their full capacity, blocking out ore. The Manhattan Mother Lode Mining Co. is about to let another 100-ft. contract in its adit.—At East Manhattan, the Manhattan Buffalo is installing a gasoline hoist at its 125-ft. shaft. The Manhattan-Mammoth and Consolidated Manhattan are rapidly opening up their ground by means of adits and developing the same orebody, which is the largest in the district.

Manhattan, July 21.

NEW MEXICO.

GRANT COUNTY.

About 50 men are building a wagon road from Lake valley to the Grand Central mine over the range, in Carpenter district.—A lead-silver strike is reported from Chloride flats, near Silver City. It was made at a depth of 60 ft. by F. A. Walter and W. J. Murray, who have a bond and lease on the Surprise. A shipment was made last week to the smelter.—Two cars of high-grade zinc ore were shipped last week by the Empire Zinc Co. at Hanover to the plant of the Mineral Point Zinc Co. at Iola, Kan. William Swancoat, the superintendent, expects to increase the force at the mine.—In view of its plans to increase operations, the Comanche Co. has appointed L. J. Carter superintendent of the mines at Leopold, and John Hodge has been appointed shift-boss.—The Santa Rita Mining Co. is averaging a shipment of one car of high-grade ore daily. In addition, considerable prospecting is being done. Five shafts are being sunk to develop orebodies in different parts of the mine. Forty lessees are at work and the concentrating mill is running steadily.—The experimental concentrator of the Hermosa Copper Co., near Hanover, is running satisfactorily. The plant was built by J. W. Bible and associates several years ago on the Hanover branch railroad, to be used for custom work. It has been much altered and is being used as a testing plant by the Hermosa Copper Co.—Five hundred tons of iron ore per day are being shipped by the Colorado Fuel & Iron Co. from Fierro. This output is to be

increased to 1,000 tons daily, and a few weeks ago a night shift was put to work, which has now increased the production to 800 tons. The company has acquired the Brockman iron mines in Hanover canyon.

TAOS COUNTY.

The American Metals Co. has installed three Wilfley tables and two vanners in its mill at the Modoc mine, in Organ district, and is turning out high-grade concentrate.—At the Bennett mine, in the Organ mountains, a shoot of copper glance has been struck on the lower level, south drift. It is six feet wide. An assay across the vein gave 26% copper. The drift has been driven 16 ft. and is still in ore.—The Comanche Consolidated Copper Mining Co. has men under contract in the Cuchillos, near Edwards camp. It is the intention to sink to 700 ft. J. B. Taylor is in charge during the absence of H. B. Johnson.—Chicago capitalists closed a deal with Nicholas Galles, receiver for the Torpedo mine, for \$325,000. Machinery will be put in to unwater the mine and develop it and a smelter will be erected. The Torpedo is a copper property.

OREGON.

BAKER COUNTY.

(Special Correspondence).—Forty miles northeast of Baker City, and 72 miles by wagon road, is situated the property of the Cornucopia Mines Co., of Oregon, consisting of 400 acres, mostly patented, and three mill-sites owned and operated by John E. Searles, of New York. It began producing in 1896 and has yielded \$1,500,000 in gold. The equipment consists of a 20-stamp mill, power and mining plant. Electricity, generated by water power, is transmitted to motors—one 200 h.p. at the mill, one of 200 h.p. for driving air compressors, and one of 100 h.p. for the hoist. Machinery and buildings represent an outlay of \$200,000. The development in shafts and adits will total 10,000 ft. An adit, 1,000 ft. long, reaches the workings. The veins are sharply defined and the ore is in part free-milling, from 10 to 60% of the assay value, in gold, being recovered on the plates. The veins average six feet in width and the filling of quartz and sulphides will average \$20 per ton gold. The concentrate runs from \$150 to \$200 per ton. There are 100 men employed and the output approximates \$40,000 per month. This property is at present undergoing many changes, which have given an impetus to mining in the surrounding country. Mr. Searles recently began to give personal attention to his Oregon interests, and made a tour of inspection of his Western mines. After spending a couple of weeks at Cornucopia he went to Eldorado county, Cal., where he owns the Union mine, an old producer, now operating 40 stamps. Returning to Oregon, he began the execution of plans outlined on his first visit. His engineer, John Hagel, and an assistant, are now preparing for the installation of 30 more stamps and the erection of miners' cottages. The intention is to abandon the boarding-house system and encourage the employment of men with families. Probably 300 men will be employed before the end of the year. There is said to be now blocked out, in this mine, ore sufficient to run 50 stamps continuously for two years.—Chas. F. Soderling, manager of the Queen of the West Co., is developing a group of claims lying above the Searles property. His pay-roll last month was \$6,300. Soderling represents Minneapolis people. The company owns six claims, a mill-site and water power. A 10-stamp mill is nearing completion at the foot of the mountain, 3,000 ft. below the mine, to which a tramway a mile long is being built. The vein is six feet wide and the ore will average \$20 per ton in gold. One thousand feet of work has been done on ore. A recent strike is reported here of ore said to average \$100 per ton. The mill will be completed this fall.—George W. Boggs, manager, representing Spokane men, is working 20 men on another property on Cornucopia mountain. He is building a 10-stamp mill on Elk creek, including a cyanide plant. On the foothills of Eagle mountain, and lying between it and Baker City, two properties are working on the copper belt. The Indiana mine, J. W. Messner, manager, has reached a depth of 300 ft. and is driving on the vein. The breast of ore is 30 ft. wide and will average 8% copper and \$4 per ton gold. D. W. C. Nelson, manager of the North American, at Burkemont, is down 350 ft., and the shaft at

the bottom is in sulphide ore with traces of copper glance. This shaft passed through 100 ft. of ore containing native copper, the ore dipping across it, before it reached the sulphide zone. These two properties have each a good working equipment and machine-drills are employed.—South of Baker City, and just over the line in Humboldt county, Nev., a recent strike was made by James Ellis, of Sumpter. James A. Howard, of Sumpter, sent Ellis into this district a month ago, on information which he considered worth the venture. Ellis reported the discovery of a mineralized region, 32 miles from Denio, Ore., and 10 miles from where Quinn river crosses the stage road running from Denio to Winnemucca, Nev. From the surface of an 18-ft. vein in this district, Ellis sent samples to Mr. Howard carrying \$200 per ton gold, beside silver and copper. Howard was in Baker City recently, and with Thos. C. Burke and others sent an outfit on the road headed for the Nevada line. Since then other mining men who are not anchored here are rushing south to Denio.

Baker City, July 21.

SOUTH DAKOTA.

LAWRENCE COUNTY.

The Homestake Co. has started the electric motors in the Monroe mill (formerly the Caledonia) at Terraville, and the 100 stamps are now being operated by electric power. This is the first step of the Homestake in the utilization of the water-power of Whitewood creek. A large generating station has been completed at Englewood, and from that point the power is transmitted across the hills to the various places where it will be used. The Homestake Co. also intends to operate the Mineral Point (formerly Father De Smet) 100-stamp mill, at Central City, by the same power, and within a few days the motors will be started. The operation of these plants by electricity marks an important event in the history of the Homestake. The company proposes to operate these two mills continuously by electric power, and as fast as more electric energy is developed, will utilize it at other places on the property.—In order to gain depth on the vein and prospect it for 200 ft. along its course, the Iowa Co., at the head of Sheeptail gulch, near Central City, has started work on an adit. This adit is being driven toward a vein through porphyry, which is also gold bearing. There are several large veins on the property, all of which are to be explored. George V. Ayres, of Deadwood, is president of the company and O. N. Brown general manager.

PENNINGTON COUNTY.

The consolidation of the Holy Terror and Egyptain mines at Keystone is reported to have been accomplished at a recent meeting held at Southampton, Mass. W. F. Collins is manager.—The new 10-stamp mill at the Cumberland mine, near Hill City, is nearing completion, and F. C. Crocker, manager, expects to have it in operation in 30 days. The plant will contain 10 stamps, concentrators, and devices for close saving. The Cumberland property includes the J. R. mine, in which former owners lost the ore-shoot. The present management has been able to re-discover the pay-streak and develop it to such an extent as to justify the building of a mill.—Frank Hebert has recently started a two-stamp Tremain mill on ore from the Tin King mine, at Oreville, and is reported as producing a good grade of concentrate. The mill is equipped for fine crushing, and with a Wilfley table is making a fair saving. Mr. Hebert recently sold the Clara Bell mine.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The Ben Hur Gold Mining Co. is to be re-organized. The mine has been closed down without paying off, but an early settlement is expected.—F. M. Gates, L. H. Mason and P. H. Walsh of Republic, have organized the Mountain Boy Mining Co. to operate a mine of that name at Park City, on the south half of the Colville reservation. This property has produced some rich ore.—On the Colorado mine, situated on the south half of the reservation, a vein of silver-lead ore has been opened by an adit. The ore is two and one-half to five feet wide and assays from 50 to 75% lead and 30 to 235 oz. silver per ton.—The Winnipeg Mining Co. reports that ore has been encountered in the Hawkeye adit on its property.

The Oversight Co. has struck shipping ore between the West Side adit and the Great Northern shaft. The ore will be shipped when the Belcher Mountain railroad can transport it to the smelters.—The upper tunnel on the Anonymous has crossed the vein 60 ft., of which over 30 ft. is oxidized ore and iron sulphide of good value. The lower tunnel is in 300 ft. The company proposes to start another tunnel which will run 1,000 ft. to the vein at 600 ft. depth.

The Red Metal Smelting Co. has been incorporated to establish a smelter at West Fork, on the Sans Poil river, 15 miles south of Republic.—The Mineral Hill Mining & Tunnel Co., operating near Danville, in the northern part of this county, has received a compressor. This company has a large group of gold-copper-bearing veins. On the Minnehaha, one of the claims, a shaft was sunk 150 ft., to a flat fault. An adit was run 275 ft. and then discontinued. Lately another was started which is expected to tap the old workings on the 150-ft. level. It is here the compressor is to be operated. Several carloads of \$20 ore were shipped from the old workings to the Granby smelter, at Grand Forks, B. C. A second shaft, the Hercules, is 200 ft. deep and \$90 ore was shipped from it. It is intended to connect the new adit with this vein by cross-cutting.—The Washington & Great Northern and the Spokane & British Columbia Railway Co. are cutting rights of way down the Sans Poil valley to the Columbia river. These roads will facilitate the development of a wide scope of country and a large number of good mining prospects.

Republic, July 21.

CANADA.

BRITISH COLUMBIA.

(Special Correspondence).—B. E. Sharp reports that the 100-ton concentrator in operation at La Plata mine, near Nelson, is a success. Owing to the presence of zinc the companies in that district have had difficulties which are overcome by the new concentrator. The ore is mostly galena, running 60 oz. per ton.—The output of the Boundary mines for week ending July 21 was as follows: To Granby smelter from Granby mines, 15,772 tons; from Emma mine, 22 tons; to B. C. Copper Co. smelter from Mother-Lode mine, 744 tons; to Dominion Copper Co. smelter from Brooklyn-Stemwinder, 2,970 tons; from Rawhide, 264 tons; from Sunset, 660 tons; from Mountain Rose, 33 tons; to Nelson smelter from Emma, 100 tons; to Trail smelter from Providence, 40 tons. Total shipments for week, 20,605 tons; total for the year to date, 682,544 tons. Smelter treatment for the week was as follows: Granby smelter, 16,100 tons; Dominion Copper smelter, 3,927 tons; total for week, 20,227; total treatment for the year to date, 687,476 tons.

NOVA SCOTIA.

It is expected that the present financial year, which ends in September, will make a new record for low production from the gold mines, most of the miners having left for Cobalt and the new fields in Northern Ontario. A systematic geological survey of the iron fields is being made and the production from Londonderry and Ten Broek goes on apace. Several of the Government drills are in use—though at Newville the 3,000-ft. core-drill has been replaced by a churn-drill.—During the past year the output from Cape Breton coalfield exceeded 5,000,000 tons and with the expanding markets the prospects for the industry here are bright.

MEXICO.

SONORA.

The San Juan Bautista mines were famous years ago for rich ore, but were abandoned and remained idle for a long time until acquired by George F. Woodward. A company was recently formed at Washington, D. C., and development resumed. A few days ago the miners encountered 30 ft. of high-grade copper ore in opening up the old workings, and a large body of good-paying sulphide ore was encountered on another portion of the property. The miners also unearthed some interesting relics of this old camp. An old silver and gold hanging-lamp was dug up, together with other utensils. It has been only four weeks since the company began work, and it now has a producing mine and a good showing for two more, where development work is being carried on. Wm. M. Reese is superintendent and George F. Woodward is Western manager for the company.

Personals.

JAMES W. NEILL is at Pasadena.

E. GYBBON SPILSBURY is in England.

H. W. HARDINGE is at Crystal, Colorado.

H. C. HOOVER is expected in California shortly.

R. GILMAN BROWN is at Ymir, British Columbia.

E. McCORMICK is examining mines near Waldo, Oregon.

J. POWER HUTCHINS is at Elizabethtown, New Mexico.

IVAN RAGAZ is at Santa Barbara, in Chihuahua, Mexico.

HOMER WILSON, of San Francisco, is at Goldfield, Nevada.

J. H. CURLE sailed from New York for London on July 17.

ARTHUR LAKES is examining the Bull Whacker mine at Hailey, Idaho.

R. C. ALABASTER is in charge of the Etruscan Copper Estates in Italy.

FRANK L. SMITH, of the firm of Smith, Parker & Boyd, is at Los Angeles.

D. W. C. NELSON is manager of the North American mine at Burkemont, Oregon.

F. M. RAE is manager of the Gilt Edge mines, at Giltedge, Fergus county, Montana.

STANLY A. EASTON has returned to Wardner, Idaho, from a professional trip into Montana.

GEORGE W. BAGGS is mine manager for a Spokane company at Cornucopia, Oregon.

G. L. EDDY, from the App Consolidated mine, at Quartz, Cal., is in Oakland for a few days.

CHAS. F. SODERLING is manager of the Queen of the West mines at Cornucopia, Oregon.

A. E. CARLTON, of Cripple Creek, is attending the meeting of the American Institute in England.

DAVID H. LAWRENCE, of Breckenridge, has opened an office in Denver at 406 Temple Court Building.

J. W. MESSER is superintendent of the Indiana copper mine, between Baker City and Cornucopia, Oregon.

C. F. LEHMAN is supervising construction work for the Washington Water Power Co., at Post Falls, Idaho.

P. C. MCCARTHY has returned to Lake City, Colorado, from Cananea and other portions of Sonora, Mexico.

JOHN DERN, president of the Con. Mercur Gold Mines Co., has returned to Salt Lake City from a trip to Canada.

SAMUEL L. LEVY, manager for the Annie Laurie Mining Co., operating in the Gold Mountain district, Utah, has resigned.

R. H. ANDERSON is superintendent of the Sullivan Group Mining Co.'s mines near Kimberley, East Kootenay, British Columbia.

J. D. BEEBE and C. M. FUELLER, of Denver, will take charge of the new mill of the Tallapoosa Mining Co. at Yates, Alabama.

B. LASEKE and JOS. WENDELLE are in charge of operations for the Bear Hydraulic Mining Co., at Barkerville, British Columbia.

S. S. SORENSSEN has resigned as superintendent of construction with the Utah Consolidated smelter. He is visiting San Francisco.

ARTHUR LITTLE, of Sutter Creek, is the new superintendent of the Bay State mine, near Plymouth, Amador county, California.

B. J. HOXIE, lately foreman of the Keystone mine at Amador City, Cal., is superintendent of the West Tonopah mine, Tonopah, Nevada.

A. KAYE, recently assistant assayer at Le Roi mine, has been appointed to the charge of the Dominion Assay Office, Vancouver, British Columbia.

C. E. SHAFER is superintendent of the Harvard mine on Whiskey hill, near Jamestown, Tuolumne Co., Cal., and T. J. RUSSELL is mine foreman.

W. WESTON is back at his post as head of the mining department of the Denver, Northwestern & Pacific Railway after a severe illness of five months.

CHARLES A. BRAMBLE is now editor of the *Canadian Mining Review*, having succeeded H. MORTIMER LAMB, who resigned on account of ill health.

GEORGE F. WOODWARD is manager and W. M. REESE is superintendent of the San Juan Bautista Mining Co. in Montezuma district of Sonora, Mexico.

JAMES CAMPBELL, of St. Louis, has taken the presidency of the Lluvia de Oro Gold Mining Co., upon the resignation of H. E. CARY, formerly of Salt Lake City.

ROBERT J. COLEMAN, formerly manager of the Samuel Newhouse interests, has been appointed manager of the Lluvia de Oro mines in Chihuahua, Mexico.

CHARLES S. DOWNING, of Kansas City, secretary and treasurer of the Wellington Mines Co., is now at Breckenridge, looking after that company's interests there.

JOSEPH WEISSBEIN, of Grass Valley, formerly of the Grass Valley Exploration Co., is now manager of the Gold Flat Consolidated Gold Mining Co., near Grass Valley, Cal.

ROBERT MUSGRAVE, formerly with the Copper Queen Consolidated Mining Co., of Bisbee, Arizona, has been appointed general superintendent for El Tigre Mining Co., at Yzabel, Sonora, Mexico.

E. J. RADDATZ, who for seven years has been superintendent of the Honerine mine at Stockton, Utah, has resigned and has been succeeded by W. K. MURDOCK, formerly assistant superintendent.

FRANCIS A. THOMSON has resigned his position as superintendent of the New Western Reduction Co., at Goldfield, Nev., and consulting engineer to the Round Mountain Antelope Mining Co., and will shortly proceed to Colorado.

J. D. IRVING, editor of *Economic Geology*, will be absent in Europe in August and part of September. During this time the conduct of the journal will be in the hands of WM. SHIRLEY BAYLEY, who may be addressed at South Bethlehem, Pa., or Echo Lake, Morris county, New Jersey.

W. R. THOMAS, who was the principal factor in the organization of the Central Eureka Mining Co. at Sutter Creek, Cal., and of which mine he has been superintendent for twelve years, has resigned, being succeeded by his brother, JOHN R. THOMAS, who during these years has been foreman of the mine.

Obituary.

THOS. H. SIMMONDS, superintendent of the Bunker Hill and Sullivan mines, at Wardner, Idaho, died at Guadalupe mine, near Los Gatos, Cal., July 14, at the age of 47 years. He was a native of Devonshire, England, and had been prominent in mining on the Pacific coast for the past 15 years.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

IN every mill or mine the management ought to be able to give a reason for doing anything in a particular way.

THE loss of velocity, in a falling stamp, due to friction is about 25%. This friction is mainly due to the contact between the stamp and the guides.

BUILDING STONE is mineral. The Supreme Court of California has decided that granite quarried for industrial use is mineral within the meaning of the law.

THERE IS, on the Colorado statute books, a law which makes it a misdemeanor to jump or take by stealth or violence a mining claim in the possession of another.

IT IS BAD PRACTICE to place a heavy course of brick or stone on top of a boiler, for a thinner coating of magnesian material will answer every purpose and is superior to the brick and much lighter in weight.

TOO HIGH a heat in the reverberatory will cause the ore either to form matte or to convert the iron oxide to metallic iron, which may render subsequent treatment by either chlorination or cyanide process futile.

THE first great cave in the Comstock mines occurred July 15, 1863, when about half of the workings in the Mexican mine collapsed to a depth of 225 ft., much of the debris crushing into the works of the adjoining Ophir mine.

To follow closely an honest and subtle controversy; and to have arrived at a definite opinion upon some general question of real and practical interest and complicated reference, is assuredly the most educational exercise in the world.

THE TOTAL present visible copper supply of the world, according to an authority, is less than 10,000 tons. So long as the demand continues, and the supply does not increase, the price of the metal must remain at or above 18 cents.

IN the 18th century a large proportion of the metal mines of France and western Europe generally were directed by Saxon engineers, of whom Schreiber was chief. In the 19th century they lost their vogue and were replaced by Cornish mine-captains.

OIL may be prevented from entering a boiler with the water condensed from steam by putting an upward extension on the pipe leading to the boiler, and providing it with a means of tapping off the oil that will rise in the pipe above the horizontal pipe connecting with the boiler.

PHOTOGRAPHY can be employed to good advantage in mining, both on the surface and underground. The promoter has already discovered this fact and usually makes the most of his opportunities, but he unfortunately does not always confine himself to the illustration of the property he is describing, but uses the photographs of other and successful concerns to illustrate his own proposition.

IN the year ending Nov. 30, 1889, the Mount Morgan mine, in Queensland, produced 75,415 tons yielding 323,542 oz. 13 dwt. 13 gr. worth \$6,657,424 while the total expenses were \$1,138,849, permitting of the payment of \$5,500,000 in dividends. The yield per ton averaged 4 oz. 6 dwt. 4 gr. and the profit represented 83% of the gross output. This is probably the most satisfactory mining on record.

LIMESTONE is by no means the only rock in which large deposits of lead-silver ore occur, though not an uncommon repository for that kind of ore. The noted lead-silver mines of the Cœur d'Alene district of Idaho mostly occur in quartzite. In some districts of Arizona, and elsewhere as well, lead-silver ore is found in andesite, and the noted lead-silver ore deposits of Broken Hill, N. S. W., are in garnet schist.

LIGNITE is the lowest grade of coal that is recognized. It is commonly known as 'lignite,' 'brown lignite,' or 'brown coal.' It usually has a woody structure and is distinctly brown in color, even on a fresh fracture. It carries a higher percentage of moisture than any other class of coal, its mine samples showing from 30 to 40% moisture. The localities in which lignite is found are chiefly North Dakota, South Dakota, Texas, Arkansas, Louisiana, Mississippi, and Alabama.

THE MOST PROLIFIC natural-gas well usually produces little or no oil. Where a large volume of gas exists in rock strata it generally issues when tapped by the boring drill under tremendous pressure, in some instances blowing the string of tools out of the hole and wrecking the derrick. One of the most noted gas wells in the world is the McConkey, which flows 30,000,000 cu. ft. per day with a static pressure of 960 lb. per sq. in. Gas is distributed from this well through an extensive system of pipes, pressure being equalized over long distances by means of compressors.

LARGE ELECTRO-MAGNETS are in use in many foundries and machine shops for handling iron and steel. The magnet is attached to a carriage which runs on a traveling crane. It is brought directly over the load to be lifted and the electric current is turned on. It is at once magnetized, and lifts loads in proportion to its size and strength of current. The object is removed to the desired location, and the current shut off when the magnet loses its power and releases its load. By this means the time required for attaching and detaching chains and hooks is saved. Magnets of various shapes are employed in handling different forms of iron and steel.

THE DISCOVERY of rich ore in Utah was made about 1862 by soldiers from Fort Douglas, at Salt Lake City, at that time under command of Gen. P. E. Connor. The Third California Infantry, then at the post, included men who had had some mining experience in California. Gen. Connor encouraged his men to take excursions into the neighboring mountains, and mineral was soon discovered in Bingham canyon, near the site of Stockton, in Rush valley, at Lewiston, in Ophir canyon and elsewhere in the Oquirrh range and in Little Cottonwood canyon in the Wasatch range. In Bingham district, at the time of its discovery, the mountains were covered with heavy timber. The first location was called the West Jordan. It was located September 17, 1863. Mining was expensive in those days in Bingham. A keg of black blasting powder cost \$100, a shovel \$2.50. The cost of mining and the difficulties of transportation made development slow. The miners of the district passed a law which enabled a claim owner to hold undisputed possession of his claim after having performed a stated amount of work. The first shipment of ore from Utah was a carload from Bingham district. This was sent to Baltimore, Md. The most important mines, however, were producers of rich silver-lead ore—among them the Galena and Old Jordan. Many of the noted lead-silver mines of the early history of Bingham are among the copper producers of today.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Gold Dredging.

The Editor:

Sir—Mr. Curle's criticism in the issue of January 27, 1906, of the dredging industry is timely, and worthy of the attention which he evidently wishes it to receive. I will give a little consideration to some of his points, with reference to the Alaska field, and other regions.

In order to consider this question: Divide, mentally, Alaska into three provinces, (a) South Coast province, (b) Interior province, (c) Seward Peninsula province. Now eliminate all permanently frozen ground. This consideration strikes out at once almost all of the Seward peninsula, including the region about Nome, and all north of Nome to the west of the treeless area. It also bars the whole of the Interior province, with the possible exception of extraordinarily rich creek-beds, like Bonanza creek on the Klondike, where the material has been already loosened and disturbed by previous work, and portions of the Klondike river-bed. The South Coast province only remains. I would, therefore, eliminate from consideration as dredging ground at least four-fifths of the Territory of Alaska.

By the South Coast province I mean the strip extending from the southern boundary, along the coast, north and west; this includes the high frontal ranges of mountains of the Alexander archipelago, the St. Elias and Yakutat districts, Kodiak island, the Kenai and Alaska peninsulas, the Aleutian islands and the area lying between the north shore of Bristol bay and the Kuskokwim river. In the areas mentioned permanently frozen gravel does not occur.

All the territory lying east of the 149th meridian may, I think, be eliminated. Flood plains reduced nearly to base level, in which streams meander, are in my opinion the first requisite for auriferous gravels fit for dredging. Unless this prime geological feature is present, it is not likely that suitable ground exists, and the engineer wastes his time and that of his client in examining the area. As I do not own dredges, and further as I do not have cognizance of any balance sheets except those of the California companies, it is impossible for me to answer some of Mr. Curle's inquiries. I believe, however, that in Alaska there has been no successful operation up to the present time in the South Coast province. It is reported that a dredge built on the Solomon river, Seward peninsula, which has operated during the season of 1905-6, has been successful. We have no published statement about it up to the present, however. Granting the success of this dredge, it is due to exceptional, very exceptional, conditions in that district and latitude, a repetition of which one may not expect to encounter. I therefore unhesitatingly condemn the Seward peninsula as a dredging province. By this I do not wish to say that rich placers do not occur there. The gold is there, but among the methods of working, dredging is not to be considered.

The portion of the South Coast province which appears most promising for dredging lies to the west of Cook inlet, the Sushitna river and to the south of Bristol bay. The tributaries of the Yentna river, which is itself a tributary of the Sushitna, should be investigated. Outside of the area above named, I know of no Alaska area which is worth the dredge-investor's prospective consideration. Mr. Curle asks, How many payable dredging areas are known in the world? I should say portions of California, including the Feather and Yuba river areas, and parts of New Zealand. As regards probable areas, I may be permitted to suggest eastern Russia. I witnessed dredge

construction there in 1902. I have heard that several dredges have since been constructed. The factor of climate, to which Mr. Curle refers, needs some definition. If he refers to permanent frost in the gravel, I am in entire agreement with him, and would offer the same objections to the Olekma, Vitim, and Amgoon districts as to the Nome district. If, on the other hand, he refers to the disadvantage of short working season to which northern areas are subject, I do not think his objections altogether valid, as I believe the Ural offers an extensive and promising field for exploration.

The Atlin district is, I will admit, an extremely hazardous locality for dredging. The gravel is not particularly rich. By this I mean that the ancient benches, if worked as a whole (and there is no other auriferous alluvium to be considered there), will not run over 20c. per cu. yd. The wash is extremely heavy, and the thickness is above 90 ft. except in very limited areas. The season does not exceed 150 days, and even this is long for that region. For the matter of gold and its profitable exploitation by some form, Atlin is not without possibilities, but the method will have to be some other than dredging.

Dredging in South America is a fact, but the conditions of access to most of these regions have hitherto been prohibitive, and it may be said that dredging capital will turn its attention to many other parts of the world before hazarding investment in South America. Recently we have heard of a gold and diamond dredging field in the vicinity of Diamantina, Brazil. The ground is now being explored and I understand the gravel is being drilled. It is possible there is a profitable field for dredging investment in this isolated region, but it will be some time before results can be given to the mining public.

Mr. Curle says that probably one-third, or even one-half, the dredges started in New Zealand have worked at a loss. This fact is not a condemnation of a dredging province. In California, outside the comparatively small area about Oroville, Marysville, and Folsom, there are many so-called dredging districts, but the investigator finds that the word dredge is much more common than the word dividend.

In the United States proper, with the exception of the operations already noted in California, the public knows of no profitable gold dredging, from authenticated published statements, although in Montana, Idaho, Arizona and Colorado dredging operations have been attempted, and there are rumors that some dredges have been made to pay. Georgia has furnished one small patch of dredging ground which I believe was payable, namely, that of the Chestatee river, below Dahlonega. I do not think it impossible that limited portions of river beds in auriferous areas of North and South Carolina and Georgia may yet be profitably dredged. It is highly probable that in Burma and British India dredging fields will yet be found. The peculiar conditions of weathering which exist there in the auriferous belts should afford the proper conditions for soft bedrock, and the portions of the river flood-plains, lying midway between the sources and the sea, should be prospected.

In regard to the amount of gold which is produced yearly by dredges, Mr. Aubury has told us from reliable data how much is produced in California, and I believe this represents nearly the whole product of the United States. The amount produced in New Zealand I have no means at present of knowing; the amount produced in other parts of the world is at present insignificant. The estimate of future production in California is conservatively \$200,000,000, as may be deduced from Mr. Aubury's figures.

I should say that the number of dredges in all parts of the world which are working at a profit does not exceed

one hundred. Of the number of dredges which were once worked and are now not working, one can form only the roughest estimate. If one hundred are working at a profit, it is safe to say there are five times this number idle or abandoned. Although this seems a large penalty to pay for experimental work, if the expenditure eventually results in the establishment of a sound producing business in various parts of the world, it will not be considered excessive.

The precise costs of dredging in various localities are probably known to Mr. Curle as well as to anyone. Eight cents at Oroville, 80c. in the Klondike, and 50c. per cu. yd. in the Seward peninsula of Alaska, are the figures of which I feel fairly sure. The high cost in the Klondike is where gravel is thawed by steam-pipes in front of the dredge as it progresses. The Alaska figure assumes a season of 120 days, and delays are occasioned by annual, but not permanent, frost. New Zealand costs are said to be very low, but I have no figures at hand.

Regarding costs in the Ural region, which I have indicated as the best field in the Russian empire, all conditions considered, I would allow an average season of 180 days. The cost on this basis, assuming a ten-year life, not to exceed \$500 per acre for the ground as purchased, \$75,000 each for the dredge installations with a capacity of 1,500 cu. yd. per day, in 30-ft. average ground, is 14c. per cu. yd. This is taking the highest figure for operating at Oroville and adding to it depreciation, amortization, and interest on total invested capital, making an extra charge of six cents per cubic yard.

In general, the cost of dredging is not seriously affected by nature of deposit for the reason that dredging in deep ground, for example 60 ft., merely increases the first cost of installation and does not seriously affect the operating cost. Ground containing numerous and large boulders cannot be dredged at all, so this kind of deposit need not be considered. Likewise ground with too great an overburden of turf or muck cannot be profitably dredged. Likewise ground which is too shallow cannot be dredged, but should be worked by steam-scrapers. By elimination of the objectionable types of ground, it will be found that the cost of working real dredging ground will not greatly vary in California, Burma, or European Russia. If anything, the operating costs will be somewhat greater in the two latter countries. As regards power, where dredges are operated as at Oroville by a general power-system, the cost will be less than for self-contained dredges operated by steam, unless fuel is remarkably cheap.

Prospecting of dredging ground should be done by pit-sinking if possible; as this method is rarely feasible, drilling with churn-drills is generally requisite. This subject has been so thoroughly discussed recently that I shall leave it to those best qualified to answer. For the determination of the proper factor to apply in each case of an examination, I unhesitatingly recommend the sinking of a pit around the drill-hole if possible, in at least ten per cent of the number of holes drilled, to check the drilling results.

The proper valuation of dredging ground should be made on a system which eliminates all doubtful territory from consideration. For example, in a base-level valley suitable for dredging there may be an average width of 1,500 ft. of gravel-flat covered by marsh, forest, underbrush; in any of which an open-cut to accommodate the dredge-hull may be dug. There may be a meandering stream four or five feet deep, which is subject to spring freshets occupying 500 ft. of a given cross-section of the valley. The danger of working in this stream should be taken into consideration, as the dredge may be wrecked by a flood, if operations are attempted in the present water-course. Let us say that all the area outside the

limits of the river is workable. But at best, only a small area near either bank in the river itself is dredgable, and it is a risk to allow for the gold which may underlie the main body of the present stream. To this it may be objected that in certain dredging areas the auriferous channel is coincident with the course of the present river. I reply that an area presenting such geological conditions is not in a bona fide dredging province, as it does not represent dredging ground founded on the Oroville province as a type; namely, where the gold is fine and distributed with a fair amount of uniformity over a wide, comparatively shallow area.

In further considering the valuation of dredging ground, I would urge the suggestion that while operating expenses have been published in considerable detail, the value of dredging ground has few data concerning the cost of ground and equipment. If operating expenses at Oroville, for example, are being reduced to five cents per cubic yard and under, what additional cost per cubic yard must be figured for the annual consumption of the ground, and to allow for the amortization of the machinery? Scrap iron is no great asset, and that is all a dredge amounts to after the gold which it is winning for its owner is removed.

I think it must be confessed to inquirers like Mr. Curle, that the proper system of valuing ground on such a basis as to show the probable net proceeds of the operation, has not been discovered. At least I have never seen published a balance sheet of a gold-dredge which shows how much it earns over all expenses. Oroville has given us the data for estimating actual as against theoretical work in cubic yards handled. The present excessive cost of, and time consumed in, repairs will probably be reduced, but Oroville experience gives us the best basis for estimating, as yet. The life of the property can be determined by prospecting, and the yardage and cost of each dredge being a fairly well-determined factor, operating cost being estimated from local conditions, the eventual net proceeds ought to be foretold with a fair degree of accuracy. No valuation of dredging ground which does not thus allow for amortization of the total preliminary expense of acquiring, prospecting, and equipping, in addition to fixed charges for operating for a given length of time, appears to me worthy of consideration.

C. W. PURINGTON.

Denver, July 15, 1906.

Milling Gold-Bearing Cement.

The Editor:

Sir—Having at different times abstracted from your columns and your book on 'Stamp Milling of Gold Ores' data that have been of value to me, I herewith hand you some facts concerning the extraction and milling of some 80,000 tons of gravel that may be of interest to some of your readers. The mine in point is situated on the Big Blue, North Blue, or Ancient Yuba channel, according to what authority you consult, at Blue Tent, Nevada county, California, and is known as the Canfield or, more properly, the Drescher mine. A tunnel has been driven under the channel for 1,500 ft. in a southwest direction from Cody's ravine on the east rim, tapping the channel by a 40-ft. raise on the short arm of one of its swings.

From this raise, drifts are swung each way to the limits of the claim. Power-drills are used in the tunnel and in gravel. Mules are employed in the main tunnel, transporting ten 14-ton side-dumping cars per trip. A maximum of 105 cars per 10-hr. shift has been landed in the mill. The mill is equipped with two Blake rock-breakers. There are double bins, with Challenge self-feeders and three 150-lb. stamps for prospecting operations, and twenty 1,000-lb. stamps for regular work. Water under several hundred feet pressure operates Pelton wheels and gives the power required. The gravel varies in charac-

material fixed in parts, while Fig. 2 is a cross-section through X-X of Fig. 1.

The tube-shell A of the grinding-mill is shown in Fig. 1 and 2 in part and broken, as it is only necessary to show a portion to illustrate the different formations or segments B fixed and which may be fixed therein. Fig. 2 being a cross-section only, the depths of the formations or segments B are shown, but Fig. 1 being a plan, their shapes are shown more fully so that the idea of their purpose can be fully seen while the rough stones C shown in both figures quite illustrate the advantage of their use.

The frame and box formations B, hereinafter called segments, are made with or without bottoms of iron, steel, or other suitable material and in convenient sizes shaped to fit inside the tube-mill, as shown in Fig. 1 and 2, and to retain the lining material in position. The segments B may have ribs or bars D preferably shaped across to help hold the lining material C in place and so as to limit and reduce the size of the segments B into smaller compartments E to suit the particular nature of the lining material used, or rib or bar formations D may be used by themselves without outer frames.

The outsides F of the segments B may be formed plain and made to the radius of the tube-mill and so form an arch which will key each segment B in position, or the outsides of the segments B may be rabbet-formed so as to interlock with grooves therein into which locking-bars of iron or steel or other suitable material may be put. The segments B may be bolted or otherwise suitably connected to the tube-mill, but as a rule this will be unnecessary.

To prepare the segments B for use they are placed upon a firm surface approximately of the same radius as the inside of the tube-mill when they, the segments B, are well filled with the lining material either in the form of concrete K or of rough blocks of stones C, the stones being jammed in tightly and the interstices between them being filled and rammed with cement, concrete or cement mortar M or suitable material which can be poured in, in the shape of grouting, if the spaces between the stones are small. The lining material may be fixed to be quite rough as shown at C in Fig. 2 and it will preferably be made to project in irregular formations above the edges of the segment B and ribs or bars D, as it will thereby protect the edges from undue wear, and by its irregular surface assist the grinding capacity of the tube-mill or machine. The lining material may be of quartz or any hard rock or material that will do the work required of it.

After giving the cement concrete or the cement mortar M or concrete K or other lining material in the segments B ample time to set hard, the segments B are built into the tube-mill or machine with cement or other suitable binding material and the locking-bars are driven in when found necessary to use them. If found advantageous to do so, the segments B may be built into the tube-mill or machine empty in the first place and then the different compartments can be filled with the lining material in the manner above described. When the different segments B have been fitted to within the tube-mill or machine and the lining material filled and fixed therein, the tube-mill or machine will be worked in the usual way but with a much more effective and marked result than is now obtained without the use of the lining material herein specified. After the tube-mill or machine has been working for some time, the lining material should be examined, and if any of it is found to be faulty or unfit for use, the segment B into which it is fitted or fixed can be re-fitted by having the faulty lining chipped, broken and taken out and fresh lining material filled in, in the manner already described.

Crushing and Grinding Practice at Kalgoorlie.

WRITTEN FOR THE MINING AND SCIENTIFIC PRESS
BY ALFRED JAMES.

At a moment when one hears so much as to the relative advantages of stamps and the ball-mills, tube-mills and pans, one is apt to overlook the particular practice which has led to the introduction of a special type of machine to effect a certain definite reduction on a definite class of ore. Thus, for example, pans were introduced at Kalgoorlie to collect coarse gold from the furnace product, to get rid of soluble salts before cyaniding, and to grind coarse on sintered particles of ore. For this purpose pans have proved remarkably successful and if the all-roasting process had continued unchallenged, probably they would have maintained their superiority unquestioned.

But the advent of Dr. Diehl and bromo-cyanide changed all that, or rather, for a time, threatened to do so. Dr. Diehl claimed to be able to do away with roasting entirely, and to attain this object a new type of ore-reducing machine—a fine slimer—was necessary, and he introduced the tube-mill for this purpose.

It is necessary at the outset to bear this distinction in mind, for if the all-roasting process becomes once more universal or if it is possible by closer or improved concentration to reduce the refractory material (that is, the sulpho-tellurides) in the pulp to an inappreciable or immaterial amount, then it may be reasonably expected that, with the absence of the necessity for fine sliming, pans will prove advantageous rather than tube-mills on account of their lower horsepower per unit, their greater convenience in working, their capacity for amalgamation, and the granular nature of their product. These remarks refer to the Kalgoorlie practice only and not to districts where, for example, the finest comminution possible per horsepower unit is necessary for effective amalgamation or for a high extraction generally.

Therefore, similarly, given an ore which yields the most profitable result by roasting, we can scarcely expect stamps to be preferred for crushing purposes, because the question, for example, of drying the ore is of greater moment than the less repairs required by stamps as compared with ball-mills. The latter, moreover, appear to have the further advantage of requiring less power per ton crushed, yielding as they do an output of two tons of hard ore per h.p. day through 30 to 40 mesh or 2½ tons per h.p. day through a 25-mesh screen—a record unapproached by stamps, which require re-grinding appliances absorbing considerable power when large outputs (7 to 10 tons per stamp) are to be attained. The best practice known to the writer in this direction with the ordinary gravitation stamp is 336 tons coarse crushed by 40 stamps (1,250 lb.) for 120 h.p. plus an extra 60 h.p. for the tube-mill necessary to crush the 240 tons coarse product to, say, 30 to 40-mesh, or under two tons per h.p. day.

It thus appears that stamps will be preferred only when the ore yields a considerable proportion of gold on the plates and when roasting is not to be adopted. At Broken Hill, where there is no amalgamation, the crushing being preparatory to wet concentration, they even prefer to wet-crush in ball-mills rather than stamps, but sufficient data are not yet available to establish the economy of this practice.

As to the relative efficiency of the ball and Griffin mills, apart from the questions of cost, power and repairs, the regular granular product of the ball-mills appears so much superior for roasting purposes to the cement (fine plus coarse) granules of the Griffin mills, that it looks as if the latter would not continue in favor, though one can

quite understand their installation years ago when dry-crushing results were less established.

And now as to pans versus tube-mills: If better concentration can show a reasonably free cyaniding product, then the necessity at Kalgoorlie for tube-mills disappears with the theory of a complete non-roasting treatment, which as stated above was the primary cause of their adoption. But it is by no means yet decided—rather the reverse—that concentration, as practised in this district, is yielding a product capable of being bromo-cyanided without the very finest sliming, such as it appears tube-mills only can as yet accomplish. It must be remembered that even the finest sliming gives only comparatively fair results on the material that is bromo-cyanided. It was the amalgamation recoveries from the old Lake View and Hannan's Star plants which brought the percentage recoveries to so high a figure, and an attempt to obtain Dr. Diehl's bromo-cyanide extractions by bromo-cyanide alone without Dr. Diehl's bromo-cyanide method—tube-mill fine-sliming—is apt to yield as poor results as are shown by one of the best known mines at Kalgoorlie. Even though the ore of this mine is supposed to be comparatively free from refractory minerals, the residues are reputed to be the highest in the locality—2½ dwt. per ton.

Surely, in comparing the relative efficiencies of pans and tube-mills, an extraction test would have been more useful, more accurate and more practical than the pan versus tube-mill test published by the Ivanhoe Company. Of what value is a 150-mesh minimum when dealing with the classification of tube-mill products?

But with regard to these tests, they were not referred to more definitely in my remarks published in *The Engineering and Mining Journal*, because it was evident from the immaturity of the methods that the results of the tests were unworthy of serious consideration. One's chief regret was that names of such high standing should have been tacked onto tests so badly carried out. To those conversant with tube-mill work, it is unnecessary to insist on the absolute need of keeping the feed-pulp free from slime and for taking the finished product away from the mill immediately it is formed; but the Ivanhoe not only included a huge proportion of slime in its feed—returning the finished product to the mill instead of taking it away at once—but, by the intermediate working of the test on alternate days, actually had the flints coated with slime at the start of each daily test.

We have the extraordinary position of a man who discovers that an original feed of more than 26 tons per day chokes his tube-mill, actually feeding no less than 26.77 tons of finished slime (finer than 150-mesh), or more than he takes out (25.15 tons) for his daily output. Could anyone expect a mill thus choked to do effective work? Can anyone longer wonder why the results show only a fraction of the work done per h.p. unit consumed, compared with that done elsewhere by the same h.p. unit? And so it happens that we have seen published all over the earth, results which must be due to the enthusiasm of inexperience, rather than to any attempt or desire to deliberately mislead.

The actual daily production of the tube-mill choked with fine slime was only 16.74 tons of '—150' slime, although the daily output—including the returned slime re-ground—was no less than 43.46 tons. Could anything be more misleading than figures made out on such a basis? One is tempted to wonder why the metallurgist responsible did not go a little further and reduce the position *ad absurdum*, by returning all his finished product, thus proving that the tube-mill was doing no work at all!

The tests were thus unworthy of serious notice mainly because the lack of opportunity for the free escape or re-

moval of the finished tube-mill product reduced them to an absurdity. On the other hand the pans—especially the first pan—were allowed a much better opportunity of getting rid of their finished product, though even here the arrangements might have been improved. The first pan received only 7½ tons of slime with an original feed of 21.3 tons of sand, as against the tube-mill quota of 26.77 tons of slime with an original feed of 19.5 tons of sand only. Had some more efficient comparison of the product than the 150-mesh screen been available, the effect of the continuous re-grinding of the tube-mill finished product must surely have been apparent.

In the above remarks reference is made to the slime grinding-tests only. I have already shown elsewhere that given the ordinary costs of flints and liners in place of the extraordinary costs stated, the advantage lay with the tube-mill even apart from the considerations of limitation of output referred to above; and this remark refers also to the fine grinding (breaking down coarse sand) experiments. Setting flints and liners down at 1.75d. to 2d.—which is the ordinary cost—the relative costs per ton ground are 8.86d. for tube-mills, as against 10.32d. with pans.

In this connection it is curious that in Western Australia they should still use cast-iron linings, which appear to have become obsolete in other places. In the recent discussion at Johannesburg Mr. Leupold, general manager of the Treasury mill (using the Krupp tube) stated that he entirely concurred with Mr. Dowling as to the superiority of flint liners, "which roughly cost one-half and last twice as long as the chilled iron ones."

Pans have proved themselves reliable, efficient, and convenient where roasting is employed, but there appears as yet no proof of such efficiency on unroasted sulpho-telluride tailing; on the contrary, the evidence to date seems all in favor of the use of the tube-mill on such material.

By the way, one cannot but be surprised at the difference of opinion obtaining locally as to the working of pans. No two neighboring metallurgists seemed to be of the same opinion. Thus at the Ivanhoe, the compensating-weight rings are highly thought of, and much has been published about them, but at the next mine visited, I was informed that the compensating-weight rings had been thrown out, as having proved of no advantage whatever. At the next mine I was told the old original 8-ft. pans first introduced were the best pans on the field, and these 8-ft. pans are being adopted for the most recent plants. There is need for authoritative work to be done in this matter, and I hope that Messrs. Klug and Taylor will continue their valuable investigations into the subject.

A curious result of the introduction of electric power is that ball-mills (No. 5) formerly rated at 17 to 24 h.p. (steam) are now rated at 40 h.p. (electric). As a little over 200 h.p. (steam) is running nine of these mills at Kalgoorlie with three fans and all the shafting, and as 24 h.p. is about the highest figure indicated for a No. 5 Krupp mill with full charge and running 10% over normal speed and including shafting, etc., there must either be a lamentably poor efficiency of the electric motors or else the electric rating is inaccurate.

LOGICAL CONSEQUENCES are the scarecrows of fools and the beacons of wise men.

THOSE who refuse to go beyond fact rarely get as far as fact; and any one who has studied the history of science knows that almost every great step therein has been made by the 'anticipation of nature' that is, by the invention of hypothesis, which, though verifiable, often had very little foundation to start with; and not infrequently, in spite of a long career of usefulness, turned out to be wholly erroneous in the long run.

The Recovery of Copper from Mine-Drainage.

Written for the MINING AND SCIENTIFIC PRESS
By PHILIP ARGALL.

In a former article* I described, somewhat generally, various early methods for the recovery of copper from mine-drainage, and more particularly the practice at the Wicklow copper mines in the middle of the eighteenth century. The following notes are mostly from personal observation and in part descriptive of my own work in the Cronebane mine (one of the Wicklow group) about thirty years ago.

The Cronebane and Connorree mines were richer in copper than any others on the great pyritic vein of County Wicklow. The early day precipitation plant of the former had disappeared before my time, but the Connorree plant was in operation from my first recollection. A brief description of it will show what was the best practice for the recovery of copper from mine-drainage in the early 'seventies.

The water issuing from the pump-head passed through two or three cisterns in order to settle the grit; from the last of these it flowed into a launder about 15 in. wide by 12 in. deep, set at an inclination of about ten per cent. The bottom of this launder was strewn to a depth of four to five inches with broken cast-iron or old wrought-iron scrap, cut into short lengths, but preference was given to cast iron, and more particularly soft gray cast iron. The scrap for the 'copper pits,' as they were called, came from all over the country, and everything in the nature of iron was purchased as offered, so there was seldom much choice of material.

At intervals of about 500 ft. along the course of the precipitation-lauders, boxes or hutches about 5 by 10 ft. and 6 ft. deep, were set in the ground, slightly lower than the launders, so that the water from the latter could be diverted into the hutches at will. The irons in the launders were brushed and turned over, twice daily, to dislodge the copper precipitate and wash it into the hutches. The operation was carried out in the following manner: First, the water was turned off from a section of the launders, and when the receding water had exposed the irons, one man proceeded to brush them with a stiff birch-broom, to remove the accumulated copper and, in part, insoluble graphite; the water was then turned on with full force, washing the copper precipitate before it. The man with the first broom managed to keep slightly ahead of the flowing water, and on reaching the first hutch, turned the stream in there. The second man turned the metals over with a two-prong rake, exposing other surfaces to the action of the broom following him. The men timed their work so that the hutch was usually about full by the time they reached it. The water was then diverted from the hutch and continued its course along the main launder; the next section was then treated in a precisely similar manner, and so on to the end of the series.

The water and suspended copper which entered the hutch were allowed to settle for 12 hours, and the supernatant water drawn off through plug-holes, leaving the hutch ready for the next sweeping. By these operations the fine copper was removed from the iron and stored in the hutches until clean-up day.

The hutches were cleaned out every quarter and the precipitate passed through a screen of about one-tenth inch aperture, the coarse pieces retained on the sieve being usually returned to the launders to be further cut down by the acidulous waters. The launders were also cleaned up once a quarter; each piece of iron was taken up, brushed free of adhering copper, and returned to the launder; the finer material was shoveled out, screened

and hand-picked, the coarse pieces of copper going to one barrel, and the clean iron particles returning to the launders, while the rust and scale were, after careful washing, rejected.

As the copper contents of the solution became less, there was a tendency for ochre to deposit on the iron, usually impairing and often completely arresting the precipitation of copper. This condition of affairs could be improved, for a time, by augmenting the velocity of the flow, by increasing the inclination of the launders. It is a curious fact that a sluggish stream of partly spent mine-water would simply coat the irons with ochre, whereas a rapidly flowing stream of the same drainage would coat the irons with a skin of bright metallic copper. Furthermore, water falling for some distance on iron gives a coating of tough metallic copper, whereas the copper deposited from fresh solutions of mine-drainage, at rest, or of low velocity, was invariably granular and easily detached from the iron. In some places where plenty of fall was available, the partially spent solutions were turned down over a steep stairs, the steps of which were covered with heavy pieces of iron scrap, which in time became coated with envelopes of coherent copper that often required to be cut off with chisels, and always had to be removed by some force; these envelopes were practically malleable copper.

From the foregoing remarks it is evident that a gently sloping hillside is the proper place for a precipitation works, and on such a site the Connorree plant was laid out, offering every facility for increasing the angle of inclination, as the solution became spent; then turning the water over a stairs, where a little more copper was precipitated, and, more important still, the ferrous salts were partially oxidized. Following the stair-like structure, came large reservoirs, or ponds, in which the reactions were completed, resulting in settling the ochre and clarifying the solutions. The ponds, four in number, were about 50 by 400 ft., the solution passing lengthwise through the pond, entering another series of precipitation-lauders at the further end, and so on through four cycles of (a) precipitation of copper, (b) oxidation of the soluble salts (c) precipitating the iron in part, or the settling of the ochre and the commencement of the cycle over again with a solution considerably poorer in copper.

The copper precipitate was usually dried on cast-iron plates set over flues, through which heated gases meandered from the fire-place to the stack. The precipitate was repeatedly turned over on the plates and care was taken to prevent it from burning, which would reduce its copper tenor; the oxidation of the fine copper precipitate took place at a very low temperature, and had to be carefully watched. The dry precipitate was finally packed in barrels and shipped to Swansea, Wales, to be smelted.

In the Connorree dry-house a man, whom I often met in my school days, had dried and barreled the copper precipitate for something over 40 years, and notwithstanding the amount of fine copper he inadvertently consumed during this long period of service, he retained excellent health till beyond the allotted span of three score and ten, not even having a gray hair; but it must be recorded, he had green ones instead, his hirsute appearance, with green mustache tips and ample forelock of similar hue, together with patches of green hair around his ears, was truly startling; he was, nevertheless, a genial and kind-hearted Irishman. Many times in after years, when listening to dissertations on the poisonous nature of copper compounds, or in reading of them, I have recalled the incident of the verdant friend of my youth, and retained my original and early formed conclusions.

Fig. 1 shows diagrammatically in plan and elevation the precipitation plant of the Tigroney mine. L is the launder; H, the hutches to receive the fine precipitate at

*MINING AND SCIENTIFIC PRESS, MAY 19, 1906.

such times as the irons were brushed and freed from their deposits of adhering copper. This plant was constructed about 1860. The plates are reproduced from a paper, published by the Royal Dublin Society in 1882, of which the late Gerard A. Kinahan and myself were the authors.

In a previous paper I have stated the reason for conducting the copper precipitation within the mine, or in and adjacent to the main adit. For the first experiment, the cuprous waters were carried in a pipe to the launder I, in Fig. 5, which was carried forward at a slight inclination until the floor of the level was reached, then the launder was returned along the floor as indicated at E. This work occupied an unused and unventilated portion of the main drainage adit, the end of it in fact, and the first startling result was an explosion of accumulated hydrogen gas, which slightly burnt some of the men, and brought the Government Inspector on the scene, with the result that the workings had thereafter to be inspected by a duly appointed fireman, carrying a Davy lamp, before the workmen were permitted to enter. The precipitation, however, was a great success, as owing to the solutions being rich in copper, clear, and warm, the precipitate was unusually pure, averaging in large lots 80% copper.

At first the irons were brushed every day, and the water carrying the fine precipitate was pumped into a cement-lined cross-cut, which served as a hutch; later, however, it was found that a higher grade precipitate could be obtained by only brushing the pig iron twice a week, and this practice prevailed. The labor required to carry the pig iron in and the copper precipitate out soon proved onerous. As the level was too small to accommodate a car together with the launders, hand-barrows were used until the mono-rail system, illustrated in Fig. 5, 6 and 7, was established, where R is the rail, S the rail support, made in two forms; one for a side support; the other S', for a roof support. Holes were drilled in the rock, filled with soft wood, and the support S driven in; the rail, which was a 1½-in. steel cable drawn taut, was then placed in the saddle of the supports, which were hammered tightly around the rope to hold it firmly in the saddle. The level was very crooked, so that a rope lent itself better to the sinuous course of the drift than anything else we could think of. Fig. 7 is an enlarged view of the wheeled carriage, the mono-rail, and the side supporting hook S. The box W held 800 lb. cast iron

and was pushed along by a man, as in the case of an ordinary mine-car. This apparatus, placed in operation in 1875, was an unqualified success, and, as far as I know, it is the first application of the mono-rail system in a

mine. The idea originated with the late Capt. George Oates, manager of the property. Fig. 8 is a section of the Mosey adit, showing a form of precipitating launder (L) and car-track designed by myself in 1875. The space (C) below the spreader was to accommodate flood-waters and

also for diverting water from the launders prior to brushing and dressing the irons. The car was only used for transporting pig iron and copper precipitate to and from the Magpie shaft, which intersected the adit at 200 ft. below surface. This particular plant extended for 2,000 ft. along the Mosey adit, and had at intervals suitable hutches for collecting the copper precipitate; these were shallow winzes lined with cement, out of which the clear water was pumped prior to brushing the metals in the launders, or cement-lined cross-cuts, the mouths of which were built up with brick and cement for a height of about four feet, and into which the water carrying suspended copper precipitate was lifted by a hand-pump. The upper portion of this launder system was raked and brushed twice weekly, while the lower portion required daily attention to dislodge the ochre accumulation, otherwise the pig iron would be glazed over with ochre and protected from the action of the water. In this case neither settling ponds nor increased velocity of flow could be arranged for, and so the economic limit of underground precipitation was reached.

Fig. 3 and 4 represent in plain and longitudinal section, a form of precipitation box, designed to fill open spaces compactly. In one abandoned station of the Boundary shaft 40 tons of pig iron were exposed to the action of the mine-drainage in these boxes, which, by the way, were most effective precipitators. They were cleaned up monthly and never disturbed between clean-ups, the copper was therefore obtained in coarse crystals and of great purity.

The foregoing notes will give some idea of the extent to which underground precipitation was carried out in the Cronebane mine (1875 to 1879), and the methods used to render it successful. The enrichment of the mine-water by collecting the surface-drainage of waste-heaps, etc., and turning it down through the older mine-workings was an early study, later enlarged to the very wide field of leaching the low-grade copper ore in place. This was successfully accomplished, and I would add that this method of treating low-grade pyritic copper ore is capable of the widest application. It is nature's method but the gradual oxidation of the pyrite can be accelerated by exposing more surface to the moist air and washing out the sulphates when formed. As an instance of the completeness and speed of natural oxidation of pyritic ore the following may be worthy of note: The Wicklow pyrite is slaty and averages about 35% sulphur, with $\frac{1}{2}$ to 2% copper; the latter, however, decreases notably in quantity when depth is reached. In the 'seventies all fine passing an inch screen aperture was unsalable and went on the dumps; these dumps assayed 33% sulphur and looked like mountains of clean pyrite in 1878; they were reduced by natural agencies to heaps of brown slate in 1901, on the surface of which I could not distinguish a single particle of pyrite, and I doubt if the heaps as a whole would assay five per cent sulphur. The reduction in volume through the removal of the sulphur and iron was probably as much as 70%. The coarse pyritic ore does not, however, decompose so readily, even in a moist climate like Wicklow, but the fine, and particularly the granular pyrite, oxidizes very fast, indeed, at surface, and under certain conditions underground also. Portions of the great pyritic lode in Cronebane and Tigroney mines caved to a depth of 250 to 300 ft., crushing down and filling up stopes and drifts; this crushed lode-matter was subsequently mined from main levels driven in the foot-wall country with subsidiary drifts and cross-cuts extending through the caved ground; some of these levels if abandoned for a year would fill completely with iron and copper sulphates, while in the stopes above them, in the crushed lode-matter, the rocks of pyrite were usually cemented together with sulphate. The heat in these

stopes was intense, seldom below 100 degrees F., and in some cases reaching 140 degrees F. Where moist enough to form drops these were simply saturated solutions of sulphate; often causing nasty sores on the arms and backs of the semi-nude miners. I knew of one man who through a single drop lost forever the sight of his right eye. Of course in such places oxidation was proceeding very slowly. I was, however, much impressed with the amount of sulphates that could be washed out to enrich the mine-drainage, and quite early instituted a process of periodical leaching with mine-water, followed by a slight caving of the crushed lode-matter to obtain a circulation of air with increased oxidation of the pyrite and formation of sulphate, in turn to be removed by a second leaching and repetition of the cycle.

In East Cronebane—in the Magpie mine—the pyrite under the gossan is disseminated as a coarse sand (in blue or at times whitish clay), having about 20% of the copper existing as sulphate; the clay-gangue renders this lode impervious to circulating waters, consequently the undisturbed zone between the gossan and the solid pyrite, say 150 ft. deep, is as rich in copper today as ever. Knowing this, I succeeded a few years ago in interesting some London people in the re-opening of the Magpie mine, promising them in the zone of moderate enrichment, a width varying from 30 to 50 ft. of 2.5% copper ore. They found a still greater width of this soft clayey ore that averaged 2.79% copper, 0.0625 oz. gold, and 1.3 oz. silver per ton; about 15% of the copper in the ore mined was soluble in cold water and 10% in boiling water; in one sample 46% of the contained copper dissolved in cold water, indicating how easily this ore could be leached of its copper content by the methods I put into successful operation in 1876.

London capitalists have long looked upon Ireland as the Jews did on Nazareth—a place out of which no good could come. The promoters failed to raise the necessary funds to properly explore the property, while it fell to my lot to add to my former somewhat varied experiences a close parallel to that of the New Testament character who undertook to journey from Jerusalem to Jericho.

ARTIFICIAL DIAMONDS.—Many are already familiar with the experiments of the French chemist, Moissan, who was successful in producing artificial diamonds by the employment of molten iron as a solvent for carbon, and using the electric stove, invented by himself, for producing a degree of heat hitherto not reached. Through the intense heat of this electric stove and by sudden cooling of the molten metal, the carbon is separated in the form of very small diamond crystals. The London *Lancet* reports a further step in advance in the production of crystallized carbon through experiments of Dr. Burton, of Cambridge. This scientist has proved that the diamond is a denser form of crystal than graphite, and that a lesser pressure is sufficient for producing artificial diamonds than has been employed heretofore. Dr. Burton in his experiments used a molten alloy of lead and some metallic calcium, which can also hold a small quantity of carbon in solution. If the calcium is separated from the molten mass, some of the carbon crystallizes. The separation of calcium can, for instance, be accomplished through steam. If the introduction of steam is made during full red heat, then small graphite crystals are found in the resulting crust of lime; if the steam is introduced during a low red heat, no graphite is formed, but a number of microscopic crystals are formed, the properties of which are entirely identical with those of natural diamonds. These experiments, which may be continued, strengthen the belief that it may be possible some day to produce in the laboratory of the chemist diamonds of sufficient size and perfection to compete with natural diamonds.—*Graphite*.

An Induction-Motor Hoist.

Written for the MINING AND SCIENTIFIC PRESS
By C. F. LEHMAN.

The direct-current series-wound motor has been used for some time by many of our mines as a means of hoisting ore, but it has been only a short time since the first induction motors were installed for that purpose. One of the earliest of these induction-motor hoists is that of the North Star mines at Grass Valley, California.

The original was a double-drum friction-hoist, with a power-wheel five or six feet in diameter, using a variable quantity of water according to the requirements of speed and load. The shaft is an incline varying in dip from 8 to 35 deg., the greater angle being at the lower levels and especially at the bottom chute of the 2,700-ft. level. As water-power became inadequate for the requirements of the mill and hoist during the summer, it became necessary to make a change.

The company had in service a 50-h.p. 440-volt variable speed M motor, of the General Electric Co.'s make, with full speed of 514 r.p.m. This motor was installed at the 1,400 level to run a five-pole plunger pump, belt driven; being used only as a constant speed motor, it was not possible to run the same for hours on slow speed with the resistance as installed. It was thought best to take this motor out of the mine and use it for hoisting, purchasing a two-speed induction-motor of 75 h.p to run the pump.

A concrete foundation was built on the opposite side of the drums from the water-wheel; an extra shaft, bearings, gear-wheels and friction-clutch were fitted up so as to be thrown into connection with the shaft of the friction-wheels, the arrangement being run by the variable-speed motor, geared to the extended shaft. This makes a good and efficient hoist, which can be run directly by either water or electric power, or by both, should occasion arise. The motor for such a hoist must be one of large starting torque, and should start slowly, to avoid jerks, accelerating gradually and finally acquiring the speed for which it is designed. The speed of an induction-motor can be varied by altering the voltage impressed upon the stator, by altering the resistance of the rotor circuit, or by commutating the stator windings so as to alter the multipolarity.

The first method of reducing the impressed voltage reduces the capacity of the motor and the later method requires complicated commutating devices. By using proper resistance and suitable control in the armature or rotor circuit, a large starting effort is obtained with a limited starting current. This class of motor is so designed as to give a maximum starting torque at least 50% greater than the full-load running torque with about 50% above full-load current. When small starting torque is adequate, the starting current will be proportionally reduced.

The motor at the North Star is that of the resistance in the armature circuit, but instead of being placed in the motor itself, it is external, connection being made to the rotor by rings and brushes. The resistance is then placed under the controller to avoid excessive amount of wire. The controller for this installation is of the type T-7 and similar to those used in our trolley cars. The controller is placed alongside the water-hoist regulator and brakes, which is 100 ft. from the motor. The two sets of resistance or rheostats are on a built-up platform five feet below the floor and directly under the controller, making the wiring work easy. An extended rod with right-angled gears and rods was attached so as to operate the controller from either side of the landing, to operate both compartments of the shaft. The resistance for the primary circuit is provided to reduce

the sudden rush of current and permit of a gradual increase. This resistance is practically cut out before resistance is taken out of the secondary circuit.

On our first trials, I found the secondary resistance too small for satisfactory results and had new iron girds cast at the foundry of twice the length and twice the thickness, with the result that we could hoist with full-load cars, at any speed up to a maximum without excessive heating of the rheostat. When hoisting ore, after starting, the controller is gradually turned around to the full-speed notch and thus the installation works at its highest efficiency 95% of the time. Men are hoisted at from half to three-quarter speed.

The engineers at the hoist much prefer electric power to water, because it is easier controlled; the speed is more uniform and without such jerks at the changes of grade as are experienced when employing water-power. The reason for this is that the slip of the rotor of an induction-motor is small as compared to the sudden change of speed of a water-wheel under the same conditions, with a limited amount of power, as is the case when not automatically governed.

A test of the current required by the hoist, with cars loaded with one ton of ore, was made and the results were satisfactory, contradicting the opinion held by many that the current would be excessive upon starting, and jump from 0 to a maximum. The initial current was about 30 amperes and gradually increased as each successive resistance notch was cut out and reached as high as 110 amperes. The higher current was not reached until the car was running on the higher speeds and steeper grades. The average current was 60 amperes, or five amperes less than the full-load current.

It is my opinion that the induction-motor will be the one used on most of the mine-hoists in the future, but that it is a little better adapted to inclined shafts than to the vertical, as there is a certain amount of slack in the rope or cable and the motor has a chance to start under small loads, thus doing away with a more sudden rush of current on the line. With a proper controller and resistances for primary and secondary, and a design suited for this particular load, there should be no reason why this motor should not be adapted to any hoist up to 200 h.p. at least. Of course, it is understood that where large induction-motor hoists are used and other apparatus and lights are run from the same plant, the main plant must be of large enough capacity to take care of peak loads; also the power-wires should be of ample size for a maximum load so as not to cause a drop in voltage due to higher currents.

CONCERNING bismuth, 'The Mineral Resources' of the United States for 1904 says: "The demand for metallic bismuth and bismuth compounds is small, though the quantity of metal which could be placed on the market is relatively large. For several years past the production and prices of bismuth and its manufactured compounds have been controlled by Johnson, Matthey & Co., of England, and the government of Saxony. The market is limited and the available supply greatly exceeds the demand." A reduction in the price would probably not be followed by a proportionate increase in the use of the metal. Its chief use is in making alloys which melt at a low temperature. Thus the alloy known as Wood's metal, consisting of tin 1, cadmium 1, lead 2, bismuth 4, melts at 60.5 degrees C., and Rose's metal made of tin one part, lead 1 and bismuth 2, fuses at 94 degrees C. These alloys are used for safety plugs in boilers and in automatic fire-alarms, etc.

THE King's road is the straight path of painful observation and experiment, and few there be that enter therein.

Drift Mining by Shaft.

Written for the MINING AND SCIENTIFIC PRESS
By D'ARCY WEATHERS.

Mining gold-bearing gravel by the drift method originated in California in 1851, at Brown's Bar, on the Middle Fork of the American river, and in the following years it was applied to the old gravel channels at Forest Hill, in Placer county. The practice consists in following the *ancient* and *recent* river channels, now overlaid by unproductive alluvium and often by lava, into the hill-side by means of adits and branch drifts, or by sinking shafts to the pay stratum and working it in the same manner by drifts and cross-cuts.

On Little Butte creek, near Magalia, in Butte county, the Perschbacher mine had in 1888 produced over \$1,000,000. It was originally opened by an adit 800 ft. long and an incline to the lowest workings 250 ft., vertically, from the end of the adit. Later, in 1895, it was opened by a vertical shaft 502 ft. deep. This was 5 by 10 ft. in section—double compartment—and was sunk

through lava conglomerate, wash, and basalt. It was timbered with 8 by 8-in. plates and lagged tightly with planking. There was a heavy flow of water and as the seepage from the old workings had also to be disposed of, the pumping plant included a compound differential plunger and a compound duplex pump each with a capacity of 500 gal. per min.; a Worthington 8½-in. plunger lifting 100 gal. per min. and three

relay pumps, a Dow sinker and two Hooker pumps. Two 60-h.p. boilers supplied steam for the pumps, and an air compressor, run by water-power, was installed for the machine-drills. The gravel 'lead' is stated in the Twelfth Report of the California Bureau of Mines to have averaged only from 4 to 20 ft. in width and I believe it did not exceed 5 or 6 ft. in thickness. A former manager told me that though it was extremely rich in parts, the total gravel removed did not average over \$2 to \$2.50 per ton.

The Hidden Treasure drift mine in Placer county is the largest example of this work in the State of California, if not in the world. This mine was opened about 1878 and has been working continuously since that date. The channel varies in width from 400 to 1,300 ft., and in 1896, 1,000 ft. of it had been worked. An adit of 8,000 ft. in the rock gave access to the mine and large amounts of timber were used. Some years ago the timber account was about \$1,000 per month. The gravel is not cemented and does not need crushing. It contains from \$1.25 to \$1.50 per ton and costs about 90c. per ton to extract.

Often the inflow of water in these gravel mines is so heavy as to prevent operations altogether unless natural facility is offered for the opening of a drainage adit below the lowest part of the channel or the pay-stratum.

I give the above notes simply to point out the fact that gravel mining by the shaft method is not altogether the inconsequential and hand-to-mouth operation that many

lode miners, who have not had experience in placer camps, imagine. Experienced management, of course, is necessary to bring the average proposition to a successful issue. Ore—represented by gravel—averaging from \$1.50 to \$3.50 per cu. yd. of about 3,000 lb., or, say, \$1 to \$2.30 per ton, is, and has been, worked at a profit where only the facilities of an average lode mine are available. It is true that often the expense of blasting, machine-drills, and milling apparatus are eliminated, the gravel being handled automatically by water, but in some cases it has been necessary, as at the Perschbacher mine, to use both powder and machine-drills and in other cases (for instance where a cemented gravel is encountered), an arrastra, stamp-mill, or other pulverizing machine is necessary to disintegrate and crush the material before sluicing.

Until recently no method except the application of experience and 'horse sense' was employed as an expedient for prospecting in unknown ground or in seeking lost channels. Large amounts of money have been sunk in this work and occasionally long adits have been driven only to find that the ground is unprofitable or that the channel

has turned. The days of the mine manager who only employs the so-called 'horse sense' method—which by the way is often a misnomer and stands for 'nonsense'—are past, and to-day careful surveys are made and scientific prospecting by shaft or drill-hole is done before attempting to work a placer property. In one large alluvial district, I am aware of over 4,000 holes (by drill and shaft) averaging

Fig. 1 The Blue Ravine Drift Mine.

ing over 25 ft. deep, having been sunk on a limited area. In Bowie's book on hydraulicking he speaks of "a remarkable instance of the extent to which preliminary work has been carried on." In the so-called "remarkable instance" it appears that only four shafts were sunk to prove what afterward turned out to be the largest hydraulic working in the State—a case of good luck. At the present time an experienced placer-mining engineer would stand aghast at the proposal to expend large capital on such a basis. In the subsequent description it is proposed to give a sketch of the present work being done in the Blue Ravine channel and the methods employed there in mining and gold recovery.

A few miles above the town of Folsom on the American river some old open-cut or ground-sluicing operations disclosed, years ago, an ancient channel flowing southerly and almost at right angles to the present river. It appears that this channel, for some distance at any rate, skirts the low hills at the base of the foot-hill region. The surface of the ground drops in the direction of the flow at about an equal gradient to the bed of the channel, which lies from 60 to 80 ft. below the present surface. During the last nine years several mines have been opened between the river and the Blue Ravine workings of today and a large amount of gold has been extracted. The Gray Wing and the Old Blue Ravine mine were the most promising pits and some of the gravel is said to have carried between

\$400 and \$500 per cu. yd. The width of the channel varies greatly. For some distance between the Gray Wing mine and the Old Blue Ravine workings, the pay ground was only eight feet wide and in other places it exceeded 200 ft. Much of the bench-gravel was too low grade to work.

The present Blue Ravine workings were opened in October, 1905, after prospecting by bore-holes put down with a Keystone drill which traced the channel from the old mines south; two shafts further to the southeast failed, it is said, to discover the continuation of the pay-gravel. The direction of flow of these old streams is determined locally in prospecting shafts or bank exposures by the grade of the bedrock upon which the pay-stratum lies.

Fig. 2.

In case the gravel is in a layer higher up and separated from the bedrock, its direction is told at a glance by the manner in which the smooth boulders and pebbles are deposited, overlapping one another or shinglewise, and tilted up with the higher end down stream. This is characteristic of most channel-gravel and as a rule ground in which the stones are erratically deposited is not so rich. To determine the grade, however, the bedrock would have

Finely laminated slate with quartz seams forms good natural riffles for the segregation of the gold. The nuggets and scales frequently become imbedded to such a depth that it is found profitable to excavate the top portion of the bedrock for a depth of several feet.

Fig. 3 is a typical section, north and south, across a block of the foothill country on the lower west slope of the Sierra Nevada and illustrates two ancient river-channels formed in successive ages and at different levels.

Fig. 5.

Referring to Channel A, an adit has been driven from the eroded canyon through the rim-rock to the gravel, which it drains and through which it can be worked. In the lower part of the sketch is a longitudinal section, east and

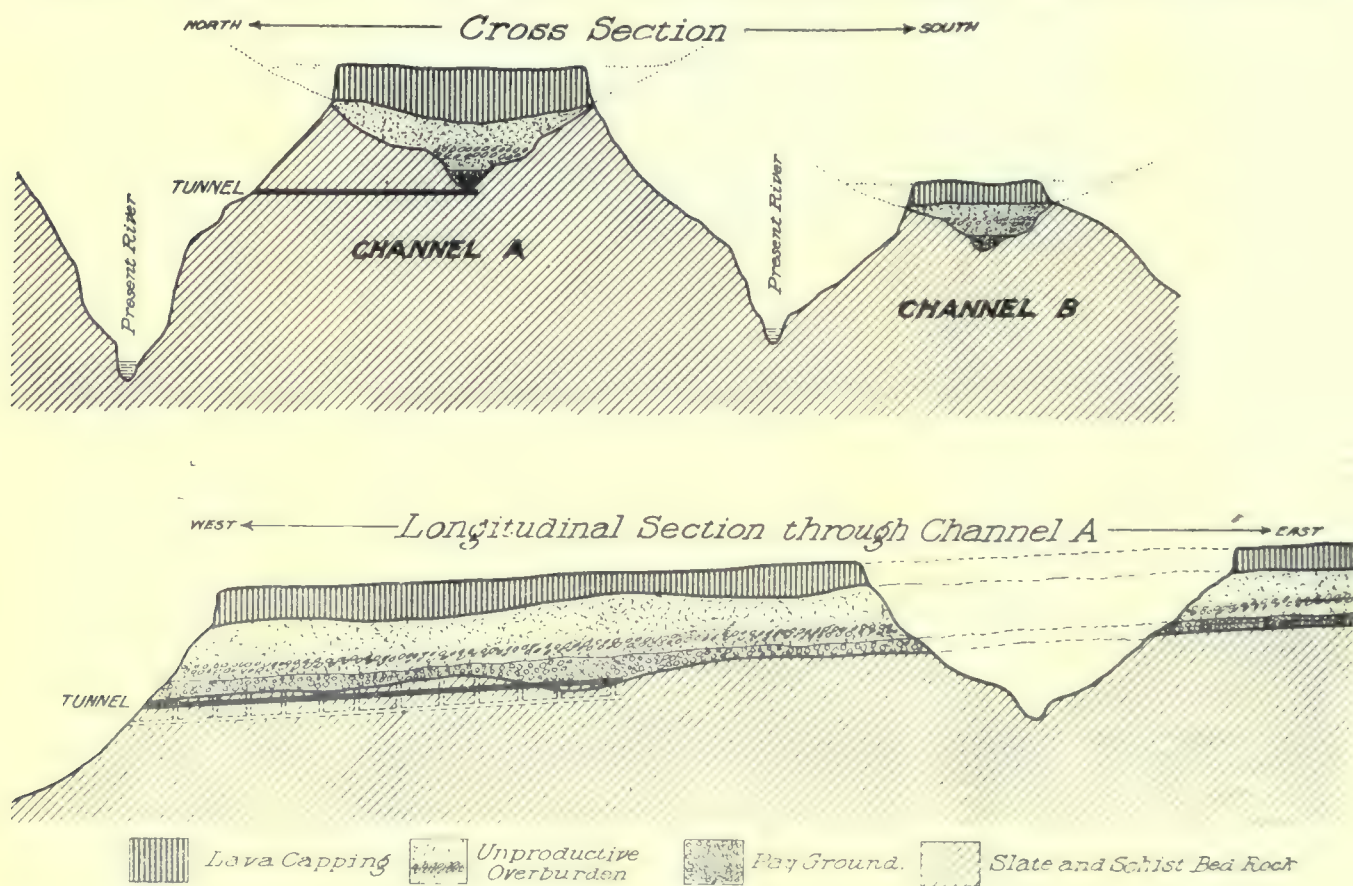

Fig. 3.

to be uncovered for some distance. Fig. 2 shows the way the rocks lie in their matrix of clay, sand, or soil; the arrow on the sketch and the pitch of the bedrock surface denote the direction of the current that formed the deposit. In this figure the bedrock is a schist, the jagged edges of which, being pointed up-stream, form natural riffles.

west, following the course of Channel A from the face of the hill above the valley back to where it has been eroded by a north and south ravine. At the right of the sketch may be seen its continuation through a higher hill. In this figure is shown another method which, when the natural facilities allow it to be adopted, is most advantageous. Here the adit has been driven up the slope of

the channel and partly in the bedrock; drainage and grade for handling the gravel are afforded from the start. An alternative method might be adopted here by driving a drainage adit in the rock below the working level, connecting them by a series of raises; these would act as chutes, the gravel being dropped down and sluiced to the mouth either by the contained water or by a supply that could be brought from the outside. A riffle or gold-saving system could be placed in the lower adit. Many other variations of this system of mining by adits could be illustrated were space available. In the following account, however, is described the more expensive method, by shaft, drift, and cross-cuts, when the channel is found to continue below the flat land of the valley. This is the method adopted at the New Blue Ravine mine.

The shaft passed through the pay-ground just before reaching bedrock, at 63 ft. It was sunk in the rock for a

also varies in tightness—no machine-drills are used—and in places it can be broken with a pick without the use of powder. A 'main' or 'working drift' (Fig. 4) 5 ft. wide at bottom and 5½ ft. high, inside timbers, is driven approximately along the channel and on the grade of the bottom. At 100-ft intervals in the 'main drift,' cross-cuts called 'breast-drifts' are carried to the limit of the pay-ground. These are 8 ft. wide outside timbering. With the main drift and limit of pay-ground as boundaries, there is enclosed a panel as illustrated in Fig. 4. Commencing simultaneously at the ends of two adjacent breast-drifts, three 'breasts' or working places are broken out from each drift and pushed ahead to meet each other in the centre of the panel. The centre breasts—*a, a*, in the worked-out portion and *c, c*, in the portion being worked—are kept slightly ahead of the breasts on each side (*b, b, b*, in the worked-out portion and *d, d, d, d*, in the

Fig. 4.

further distance of 31 ft., a total of 94 ft. from surface. At 82 ft. from surface a drift has been made through the rim-rock for about 120 ft. where the gravel is again cut at a point near the bottom of channel, so that the drift will drain the mine above this level. The shaft is divided into three compartments—a skip-way, pump-way and a ladder-way; the skip-way, which is in the centre, is 4 by 5 ft., the pump-way and ladder-way are each 4 ft. 4 in. by 5 ft. The plate-timbers forming the sets are 8 by 8 in. and the latter are placed at a distance of 5 ft. 4 in. vertically between centres, the usual posts being used. The dividers are 4 by 8 in. and the shaft is tightly lagged vertically with plank 2 by 8 in. The channel at this point is about 200 ft. wide and the method of working is as follows, though, of course, under certain conditions such as the narrowing of the channel, encountering poor ground, etc., it has to be modified. The pay-stratum varies in thickness from 18 in. to 3 ft. It lies on the bedrock and

ground being worked)—and the track is laid in the centre breast. When the three breasts from each breast-drift meet in the centre, the track is pulled up and the bedrock washed, scraped, and brushed, and as much timber as possible is drawn quickly. Fig. 5 shows the scraper and brush. The former is a home-made tool, fashioned from an old file or bit of steel, one end being flat and sharply pointed and the other spoon-shaped. The brush has long wire bristles, and with these the cracks and small fissures in the rock are cleaned, for any possible gold.

Three other drifts are then started from each side and the work is carried on in this way until the 'main drift' pillar is reached. Formerly, in many drift mines it was attempted, by leaving pillars and placing a forest of timber, to hold up the roof throughout the workings; but the method here and elsewhere employed today is much more sensible and consists in letting the roof above the worked ground cave, and thus relieve the tremendous

pressure created by the weight of a heavy body of overlying material possessing little cohesion. The bedrock immediately below the gravel is generally loose and full of crevices; the loose portion is taken up and, with the boulders from the gravel, is stacked along the 'breasts'; this is necessary because an opening 24 ft. wide has to be kept intact while working. A pillar is generally left along the side of the 'main drift.' The finer material is loaded into cars holding about half a cubic yard and is passed from these through a chute into the lower or rock tunnel. From here cars, holding $\frac{3}{4}$ ton, discharge into the skip, which has a capacity of one ton.

(To be continued.)

WEIGHT TABLE FOR STANDARD CAST-IRON PIPE.—The accompanying table was compiled by G. B. Zahniser for *The Engineering News*. As may be seen, it gives the weights per 12-ft. lengths of 4 to 72-in. standard cast-iron pipe, and also factors, in the third column, for ascertaining the weight in tons of any length of, and size of, standard pipe by a single multiplication. Mr. Zahniser suggests that similar tables can be readily computed for light and extra heavy pipe.

To Reduce any Length of Standard Weight Cast Pipe to Tons
(2,000 lb.)

Diameter pipe, in.	Weight per 12-ft. length.	Multiply total length of pipe by
4	264	.011
6	396	.0165
8	504	.021
10	720	.03
12	900	.0375
14	1,200	.05
16	1,500	.0625
18	2,004	.0835
20	2,400	.1
24	3,000	.125
30	4,008	.167
36	5,400	.225
42	7,200	.3
48	8,700	.3625
60	12,900	.5375
72	18,720	.78

ARSENIC, CARBONIC AND SULPHURIC ACID, and some other minerals in solution in battery water, will usually interfere with amalgamation inside and outside the mortar. Plates become hard from various causes—chiefly from lack of sufficient gold to form a fair coating of amalgam over their surface. When low-grade rock is run the usual practice is to scrape the plates closely in order to obtain a good clean-up. This is directly the opposite of what should be done, for there is no surface calculated to catch gold like gold-amalgam itself, and where the ore is low grade, or only contains a little free, amalgamable gold, a good coating of amalgam should be allowed to accumulate on the plates, which should be cleaned up with nothing harder than the rubbers made for this purpose. The plates should never be touched with a steel chisel or scraper until ready to abandon the mine or mill. Nor is anything actually gained by the periodical sweating of the plates by pouring scalding water on gunny sacks or blankets spread over them, nor in heating them by piling on their upper surface hot sand to soften the amalgam. Such schemes are only justified at the time of a final clean-up, or when it is considered necessary to re-plate the copper plates with silver. The use of too much cyanide of potassium, or its continued use in small amounts is detrimental to plates. If battery water is too warm it will have the effect of softening the mercury, when it will run off the inclined surface of the plates in small globules. The temperature of the water may be cooled by first delivering it to a cooling-tower provided with screens at various heights through which the water falls in a shower, the temperature being in this manner reduced to a proper degree. Experiments made at the Homestake mine at Lead, South Dakota, proved the best temperature for the most successful amalgamation there was at 52 degrees F.; that above or below this temperature the loss increased somewhat.

The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

The black rock from Taxco, Mex., is Diorite-aphanite.

The rocks from Brownell, Ariz., are: No. 1, Feldspar-porphry; No. 2 is composed almost wholly of Feldspar and Hornblende, both are much altered, but the rock was probably originally Syenite; No. 3 is Hornblende-schist; No. 4 is similar to No. 3, but more altered, the feldspar being much kaolinized.

The samples from Ketchikan, Alaska, are the following; No. 1, Pyrrhotite, mono-sulphide of iron (magnetic). It may contain gold, silver, nickel or cobalt—any, all or neither of them; No. 2, Pyrite and Galena in Quartz, probably gold and silver-bearing; No. 3, Sericite-schist containing pyrrhotite and iron oxide; No. 4, Hornblende-schist containing much pyrrhotite. There is also a large amount of epidote present, the result of alteration of the hornblende.

The rocks from Whelan, Montana, are: No. 1, Chalcopryrite with stains of blue and green copper carbonate in a gangue of Dolomite, with grains of disseminated quartz; No. 2, mostly Dolomite, the brown earthy mineral is iron oxide; No. 3, Quartz with scattered chalcopryrite (copper sulphide); No. 4, Dolomite with copper sulphide. One piece is mostly iron oxide; No. 5, Dolomite—one piece shows a little copper-glance; No. 6, Dolomite and iron carbonate (the dark brown streak). The sulphide mineral is chalcopryrite and bornite; No. 7, two pieces—buff and red—both carbonate of lime; No. 8 is lime rock. The slaty structure is due to pressure, for the lines of sedimentation can be distinctly seen crossing the slaty cleavage. The white mineral on one side of the rock is crystallized calcium carbonate. The geological age of a rock is not usually material so long as it contains mineral veins or ore deposits. Whether No. 8 is of Cambrian age or not, is impossible to tell from the specimen. The ore accompanying these samples is chiefly chalcopryrite. The small green piece consists of carbonate with a little glance.

A SYNDICATE of Pittsburg capitalists is reported to have taken steps to develop a large deposit of vanadium ore under a concession from the Peruvian government. Joseph M. Flannery is secretary of the company. Vanadium melts at a high temperature, and has been introduced in small quantities in the manufacture of iron and steel, giving an alloy said to be of remarkable strength, resistance, and toughness—to such a degree as to make practicable the manufacture of armor plate and projectiles at one-half the customary weight.

ARASTRAS, or drag-stone mills, are but little used in British Columbia. There are a few, though, for the gold commissioner of Lillooet mentions the existence of two in that mining section. Under the head of 'Mineral Claims' he reports: Very little development work, other than the usual assessments, has been done on many quartz veins in the district, with the exception of the Lorne mine at Cadwallader Creek, where in 1905 four men were engaged extending the tunnel 24 ft. and crushing 133 tons of ore, in an arastra, which yielded \$2,000. Another arastra was completed late in the season for the Pioneer claim, also situated at Cadwallader Creek. The manager had only time to crush three tons of ore, which he states, yielded \$150, before being compelled to stop operations on account of frost.—British Columbia *Mining Record*.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

SMELTING FURNACE.—No. 824,383; John D. Rivard, Los Angeles, Cal.

In a smelting-furnace; an inclined chamber; a combustion-chamber below the higher end of said inclined chamber and having the throat thereof opening into the higher end of said inclined chamber; means to supply ore into the higher end of said inclined chamber; a stack at the lower end of said inclined chamber; a crucible in the bottom of said stack, and means to supply downwardly-directed blasts of hot gas into said inclined chamber upon the ore passing therethrough.

MERCURIAL AMALGAMATOR.—No. 823,577; Barlow Baldwin, Chicago, Illinois.

In a mercurial amalgamator, in combination, a tank for the mercury, a hopper for dry auriferous material, a spout extending from said hopper into said tank, and a conveyor adapted to drive the aforesaid material into and through said spout without clogging thereof, and a nearly plane horizontal distributor adapted to spread said material over the bottom of said tank without agitative stirring of the mercury.

MINE-CAGE.—No. 824,269; Frank N. Wilson, Cripple Creek, Colorado.

In combination, a cage-platform having side or edge members provided with guiding-openings, a rock-shaft journaled below the platform, a pair of levers secured to the rock-shaft, and each having arms projecting in opposite directions from the shaft, longitudinally movable chair members having their inner ends pivotally connected to said arms, and the outer ends extending through the guiding-openings, a lever secured to the shaft and extending up through an opening in the platform, a torsion-spring arranged on the rock-shaft and tending to turn the same to effect withdrawal of the chair members, and a pair of handled rods guided by the cage and extending from the lever to points adjacent the opposite sides of said cage.

DRILL SHARPENER.—No. 822,906; Clarence W. Atkinson, Jamestown, Colorado.

In a drill-sharpener, the combination with a casing, having an opening in its top and also having lower and upper, longitudinal guideways in its side walls, a die member fixed in the casing and comprising an end abutment the inner side of which is concave in cross-section and is inclined upwardly and inwardly and a portion extending inwardly from said abutment and having a channel, of V shape in cross-section, in its upper side, and a die member movable in the casing toward and from the abutment of the first-mentioned member and having an upwardly and inwardly inclined inner end, of concave form in cross-section, and also having a lower forward portion, of V shape in cross-section arranged to move in the channel of the first-mentioned member, and also having cross-heads movable in the lower and upper, longitudinal guideways of the casing; of an eccentric cam mounted between the side walls of the casing and arranged when rotated to move the second-mentioned die member inwardly, and a lever fixed with respect to the said electric cam.

PROCESS FOR THE REDUCTION OF ORES.—No. 824,663; W. Koehler, Cleveland, Ohio.

The process of treating ores which consists in subjecting them to the action of gaseous hydrochloric acid in presence of an oxidizing agent.

JIG OR ORE-CONCENTRATOR.—No. 824,623; Alonzo C. Campbell, Asheville, North Carolina.

A concentrator or washer comprising a jig-box, a series of riffles arranged therein at a downward inclination toward the outlet end of the box, a flexible cover above the riffles, a dam at the lower end of the riffles, a receiver for material passing over the dam, a discharge leading from said receiver, discharging devices leading from the box, and means for causing the circulation of air through the box.

A New Lubricator.

Those interested in the lubrication of gas or gasoline engine cylinders will be interested in the Premier lubricator, which has been but recently placed on the market.

The cup is made of the highest grade of bronze composition, the construction is compact and the general design is

Detail Sectional View of Shank, Showing Ball Check D and Baffling Cap E.

Sectional View.

good. The cup was constructed not only with a view to proper and positive lubrication, but also to withstand severe service. The filling hole is large, which users will appreciate, as it permits the use of a filling can having a large spout. Positively to insure a tight joint between the filling plug H, and top of cup, the plug is provided with a lead washer I, which material, being softer than the brass upon which it bears, will readily conform to any irregularity that might exist between these bearing surfaces. To permit of refilling the cup while the engine is running, the valve C has been provided, which can be quickly closed and opened. The stem of this valve is well packed by means of the stuffing-box J.

The regulation of the feed is accomplished by means of the valve K, provided with a fine needle point; the thread on the stem is also of fine pitch; hence a very close adjustment can be obtained. The stuffing-box L not only serves the purpose of preventing leakage around the stem-valve K, but by means of it the proper amount of friction can be brought to bear on the stem and prevent the unsetting of the valve. The object of the tube T, within the cup A, is to equalize the pressure on the oil, which permits the oil to drop by gravity through the sight-feed and thence to the cylinder.

To provide against the back pressure interfering with the proper formation of the drops in the sight-feed and causing the oil to spatter around the glass, the shank B of the cup is fitted with a large ball check-valve D. It has been found, however, that where the back pressure is unusually great, as in engines with worn piston rings, the ball check does not entirely remedy this trouble. To meet this condition, a baffling cap E has been provided above the valve C. The gases escaping past the ball-check D are effectually muffled and diffused by means of the cap E, and hence the drops form perfectly, drop freely and steadily, and the sight-feed glasses never fill up.

The Premier lubricator is manufactured only by the Lunkenheimer Company of Cincinnati, Ohio.

Why Some Machines Fail to Work.

The accompanying photograph shows, in the foreground, an old-style Wilfley table concerning which the foreman said: "She don't do much good; them tables on the other side do better." After removing the heavy roll of belting, jack-screw, timber, and other debris, it was, not a great surprise to find that the application of a straight-edge proved the table-top to be somewhat bowed, in addition to showing

many heavy boot-heel marks, broken riffles, a hole worn half through the top by a wash-water pipe which had been allowed to rest upon it, and holes worn through the bottom of the feed-launders. "Them tables on the other side" had metal frames and the tops had remained true in spite of hard usage. This example of carelessness comes to us from the Atlantic seaboard.

Commercial Paragraphs.

THE ALLIS-CHALMERS' Denver office is now in the McPhee Bldg., and their El Paso office in the Guarantee Trust Building.

THROUGH their New York works, and temporary San Francisco plant, the PELTON WATER WHEEL CO. has been executing orders as usual, and has booked new orders which will enable it to run at full capacity for many months to come.

THE WELLMAN-SEEVER-MORGAN CO. of Cleveland, Ohio, reports a contract with the Cia de Real del Monte y Pachuca, Mexico, for a large order of electric hoists, consisting of six hoists with double reels 12 ft. 8 in. maximum diam., 18,800 lb. load, to use $4\frac{1}{2}$ by $\frac{1}{2}$ in. flat wire-rope and to hoist this load at a speed of 1,000 ft. per min. with air-operated post-brakes and auxiliary hand-brakes. Also six hoists with double reels 10 ft. 6 in. maximum diam. each to handle a load of

A Concentrating Table Badly Used.

11,300 lb. at 500 ft. per min. to use flat rope $4\frac{1}{2}$ by $\frac{3}{4}$ in. with hand-operated post-brakes and one hoist with 36 by 48-in. double-drums, to handle a load of 8,600 lb. at 500 ft. per min. All the above hoists are to be equipped with three-phase, 440 volt, 50-cycle electric motors with master controller and water-cooled rheostats.

Publications Received.

THE DENVER, NORTHWESTERN & PACIFIC RAILWAY is the title of a handsome pamphlet, bound in linen, and well illustrated, describing the country through which the Moffat railroad passes, between its terminals at Denver and Salt Lake City. It has been prepared by a writer peculiarly well qualified—Mr. William Weston—one of the most capable of the exploring engineers that have helped to develop the resources of Colorado. The book or pamphlet contains valuable articles on the geological features of the coal and metal-mining tracts crossed by this railroad, and charming descriptions of the fish and game to be found in its rivers and amid its picturesque scenery. Several maps add to the usefulness of the publication.

A 'VOUSSOIR' (pronounced voo-svor) is one of the wedge-shaped stones which form an arch. The middle one is called the 'keystone.'

Editorial.

WE TAKE the opportunity of extending a courtesy to two friends.

Mr. Robert Sticht, the distinguished metallurgist, now at Mt. Lyell, Tasmania, who is a keen student and practitioner of pyrite smelting, wants copies of the MINING AND SCIENTIFIC PRESS published before 1900 containing articles on, or references to, pyrite smelting.

The assay-office of the Selby Smelting & Lead Co. is now at the works, instead of in this city, as formerly. The company used to make custom assays; this has been discontinued. It is desired to make the fact known.

IT IS AMUSING to note that stock-market reports credit Mr. Corey's domestic scandal with depreciating quotations of United States Steel common shares. The great Steel Corporation has had two presidents who have lost their moral equilibrium by reason of excessive wealth; the suddenly rich of Pittsburg are making a sad spectacle of themselves and illustrate the fact that they are an accidental sort of people, unfit for responsibility. They remind one of those who, accustomed to driving an express wagon, undertake to manage a motor-car, the high speed of which is exciting, until going faster than they are aware, they lose control and pitch into a ditch, to the relief of those on the highway, who are endangered by their performances.

ANOTHER PHENOMENAL STRIKE is announced in Nevada, in the desert known as the Granite Springs valley, lying west of Lovelocks, and a stampede is said to be in progress. A local paper, deprecating reports which tend to give such announcements the inflated appearance of a boom, modestly says that the ore from the new strike contains by assay \$67,000 gold per ton, and \$17,000 silver. The conservatism of this announcement will be realized when it is remembered that at 65 cents per ounce, solid silver is worth only \$18,957 per ton, making the ore 90 per cent silver; if the remaining 10 per cent be gold, it would add about \$60,000 to its value, but in some unaccountable manner an additional \$7,000 per ton has infiltrated into this phenomenal ore, probably by secondary enrichment from above. It is also stated by our Nevada contemporary that this vein, in compensation for its unusual richness, is only four inches wide; nevertheless two townsites have already been started in the vicinity of the new mines.

ENGLISHMEN are not irrigating the waste places of the earth with capital in these days as they did afore-time. London feels gloomy, and it is fortunate for the mining of the useful metals in North America that financial support is forthcoming from cities on this side of the Atlantic. The depreciation in the market value of mining shares at London during the last six or seven months

amounts to at least \$500,000,000, and if it had not come on top of a slow liquidation, unaccompanied by speculation, the result would have been more emphasized. Consols have gone to a new low level and Rand Mines, the barometer of South African finance, have been to nearly £5 from their former high record of £13½. The unpleasant factors are various; there is the general financial uncertainty due to Russian misgovernment, the disturbance to cash balances caused by the San Francisco conflagration, and the uneasiness in South Africa over the native uprising in Natal. A direct influence in the liquidation of mining shares is found, of course, in the political squabbles over the Chinese on the Rand, with the probability that when the Transvaal gets constitutional government next year, the first step will be total repatriation of the coolies and a sudden curtailment in the local labor supply. That prospect has made the Kaffir market ill. Unfortunately, the effect is the worse by reason of the uncertainty regarding future events, in which statesmanship and high finance will play a fateful part. It is not likely that the mining market at London will recover any of the delightful irresponsibility of boom days until these dark clouds have passed or precipitated their burden of final liquidation. Meanwhile money is accumulating and new reserves are being created for the time when the financial skies become clear once more.

Government Ownership of Coal Mines.

This question has been much discussed in a quiet way in coal mining circles this spring and summer. Senator La Follette's suggestion, with which the President is said to be in entire accord, that the remaining coal and oil lands of the public domain be segregated and reserved from sale, is attracting attention. When, prior to the allotment of lands in the Indian Territory, the coal lands were surveyed and appraised, their value was estimated by the Government agents at much more than the operators of the region were willing to pay. The first advertisement for proposals accordingly fell flat, and when after long negotiations a set of leases covering much of the land was presented to Congress for ratification, Mr. La Follette protested that the terms were radically unfair to the Indians and the Government.

That coal land, as also farming land, timber land and mineral land, have been obtained in the past from the Government at nominal prices for speculative purposes, is too well known to permit of denial. Frequently it has been obtained by devices which were at least technically illegal, though sanctioned by custom. Apparently in coal-land as in timber-land cases we have come to a new point of view, and public opinion is ready to demand a stricter compliance with the law and, for the Government, a larger share of the speculative value. To this extent the proposition to reserve such lands temporarily from entry until they can be studied and appraised will probably command public support, despite the fact that Congress refused to direct that it be done. It is reported that President Roosevelt believes he has authority to warrant such action under general laws, and some such action may be anticipated. This, of course, will only directly

affect areas in which mining is now going on, but since most Western coal mining is inextricably mixed with Western railroading, Chicago is particularly interested.

There is, however, another aspect of the case of which a much less favorable view is taken. It is believed that both President Roosevelt and Senator La Follette have in mind steps looking toward actual Government control of mines and oil-wells on public lands. It was currently reported during the last strike that if matters became serious, the President stood ready to seize certain mines and "operate them for the benefit of the public." Just how much truth there is back of this belief no one can say, but any move toward Government operation of mines will excite opposition from men familiar with the situation.

The arguments advanced to support the move are curiously like those which almost exactly a century ago led to the trial of Government ownership of the lead mines of the Mississippi valley. In 1807 the big mining region of 'the West' was in Wisconsin, Iowa, Illinois, Missouri, and the new territory of Arkansas. The Missouri deposits were covered by old Spanish and French land grants, but the others were on public lands. These were reserved from sale and placed under a mining superintendent, so that there might always be lead for the army, so that there might be no extortion, and to secure revenue. The Government did not attempt actual mining, but leased the ground in small lots on a royalty basis. The system never worked very well, and in 1846 it was abandoned. It had become apparent in the meanwhile that the army was not likely to suffer for want of lead, the people in the areas affected protested that the leasing system retarded the development of the country, and the revenue proved disappointing. It cost \$68,464.50 to collect \$145,174.40, aside from heavy expenses in the courts.

It seems likely that much the same difficulties would be encountered in any attempt to put into effect a similar system of coal or oil leases. At first glance it is not clear why the Government as a land-owner would be at any serious disadvantage in leasing its mineral lands. Possibly, if it confined itself to the same sort of a lease as is given by individual land-owners, a working scheme might be evolved. It would, however, be almost inevitably forced out of such a position, and, indeed, it has been plainly stated that one purpose of the move is to prevent the arbitrary action of a coal monopoly. To do this it would be necessary to go into actual coal mining, since mines cannot be opened and working forces organized to meet sudden emergencies. Operators could not afford to open and equip mines on Government land or elsewhere except on terms which left them the largest possible freedom of action. As a matter of fact very few mines are now being opened except on land owned by the mining company, and the leasing system in the coalfields of the Middle West is dying a natural death. The plain truth is that there are now more mines open than can work to anything like full capacity, and any monopoly of bituminous coal mining which raised the profits would lead to many more being opened. Such control as is exercised, is in the transportation of the coal. When one studies the present unsatisfactory condition of coal mining with its pecu-

liarily close relations to railroads and its large dependence on union labor, it needs no cry of socialism to make one distrust the wisdom of the Government entering the field. It is perhaps significant that the Prussian Government, even after buying heavily of the stocks of the great Hibernian company, decided it was better to be a minority stockholder than a coal-mine operator.

In general, the effects of the long contested strike in Illinois have disappeared. The mines are running much as usual, perhaps a little heavier than usual. So much coal had been stored against the strike that there was no extravagant demand upon resumption. According to figures just published by the State Geological Survey the output for the calendar year 1905 was 38,081,674 tons, valued at \$39,754,071. The Bureau of Labor Statistics gave the output for the fiscal year ending June 30, 1905, as 37,183,374, valued at \$38,689,858. In each case comparisons with the corresponding figures for the preceding year show an increase in tonnage with a decrease in value.

One of the interesting results of the strike settlement is that the operators now have a defense against local strikes. It has been a matter of contract here for some time that in case of local dispute the men were to continue at work pending adjustment of the difficulty by the State officers. Nevertheless there were many brief, but annoying local strikes. Under the new agreement a fine of \$10 per man is assessed in such cases, half going to the State treasury of the union, and half to the operators association. At the Donk Bros. mine not long since two mule-drivers were discharged, and without waiting any adjustment of the difficulty 400 men quit work. They are now just \$4,000 poorer than they were before they tried the experiment, and are not likely to quit again without previously observing the rules of the game.

Who is a Mining Engineer?

A mining engineer of high reputation writes to us this week making an onslaught on quacks and that large army of charlatans which masquerade in the clothes of an honest occupation. This is well enough; it is safe to castigate such frauds once in a while, on the principle of the small boy who shouted to his pal, engaged in a tussle, "Give him what for, he ain't got no friends!" We quite agree as to the harm done by make-believe mining engineers. It seems almost a pity that we have not got an organization analogous to the bar association of our sister profession, able to stamp the men in proper standing and capable of stigmatizing those who go wrong. That will come in the Greek kalends. Meanwhile who is to be the judge? Not we, and certainly not any individual engineer. It is difficult to arrive at a basis for agreement, because motive plays a part in determining the character of a deed. An innocent ignoramus who thinks himself qualified to pass on mining matters, may make his blunders in the best of good faith; is he then any worse than the skilful geologist who appraises a mine without any experience for such work or the otherwise honest mining engineer who advises on the metallurgical treatment of an ore without any qualifications in that department of knowledge? We have met many

charlatans in the tented fields of Western Australia, for example, and the worst deeds were perpetrated by men who had an experience of other kinds of mining under more favorable conditions and were misled more by enthusiasm than deviltry. Some of the reports that caused the biggest loss of capital were by men fully qualified in an academic way, but lacking in common sense and in the ability to understand the dependence of profitable mining upon favorable economic conditions. It takes something besides gold ore to make a gold mine. Another point of disagreement is worthy of mention. It is suggested that only the man who has his degree as mining engineer is qualified to append the designation to his name. To this we demur strongly. If the initials M. E. are to be set aside for those who have obtained the degree of 'mining engineer,' well enough, but incidentally it may be pointed out that several schools of mines authorize their graduates to use E. M.—'Engineer of Mines'—and one school, with a royal name and a bourgeois endowment, calls its men 'Associates.' This is a minor point, but the fact remains that the degree indicates merely an academic instruction which is the preliminary to the practical training that makes a mining engineer. Many men with a luminous tail appended to their name never do become real mining engineers; they remain to their life's end the simulacrum of the real thing. On the other hand, some of the very best men on the active list of the profession today have had no academic instruction; they went to work after a common school education and yet have qualified themselves for positions of great responsibility. They have become excellent engineers by a less direct path, that is all. The mental training involved in a course at college should enable a man to think more logically and to get at the heart of a problem more quickly; a school-of-mines man ought to get ahead of a contemporary who went to work without a scientific preparation, simply because he has the start of the other fellow. Whether he retains that advantage depends on the individual himself, not on the preliminaries of his life. When it comes to the labeling of those engaged in mining, we do not hesitate to say that a man who for several years has had charge of mines, surveyed them, sampled them, and advised clients in the purchase of them, is a mining engineer—more of a mining engineer, indeed, than the green graduate from the best school of mines. The confusion in the use of the name and the denial of it to others is due to the assumption that one kind of knowledge makes a complete equipment for practice. It is not so; to the academic must be added the practical—that is to say, to the information of the library must be wedded the experience of life, in the office, in the mill, and in the mine most of all. The ideal mining engineer is he who, with faculties made alert by the gymnastics of the class-room, has acquired the judgment and the sense of proportion that come from actual mining operations, who balances the ideal and the real so as to make the best of the realities of every-day work—the particular purpose of which is to be able to advise his clients how to make money—honestly.

Special Correspondence.

LONDON, July 18.

Diligent advertising of Penn-Wyoming Copper has evoked some interest in the company on the London market. A public issue of 400,000 shares of \$5 each having been made on this side, a meeting has been held here to enable the European shareholders to meet the president (Mr. E. M. Cobb) and the general manager (Mr. Norton). The following particulars are gleaned from a lengthy report of the meeting:

The Penn-Wyoming Copper Co. was incorporated in 1904 for the purpose of taking over the smelting works at Encampment, also the tramway, which cost about £85,000, and the Ferris-Haggerty mine, with all the pipe-lines, the Transportation Co., the Town Lot Co., and so on. By taking over these companies, and bringing them all under one management and organization, the Penn-Wyoming Co. is to receive the profit from every concern that has any connection with the mining, from the time the ore is broken in the mine until the copper is delivered to the railroad. The registered capital is \$10,000,000, of which \$6,000,000 has been issued in America, mostly among the directors and their immediate relatives and friends. The property is in the State of Wyoming, in Carbon county. The town of Encampment, where the smelting works are situated, is 46 miles below Walcott, on the Union Pacific Railroad. The company's tramway connecting the district with the smelter is the longest aerial tramway in the world—16 miles long. The 972 cars, or buckets, hold 800 lb. each. The altitude of the highest point in the mountain range reached by the tramway after leaving the smelter is nearly 5,000 ft. above the smelter. The high-grade ore, running more than 8% copper, goes direct to the smelter, while the poorer ore is concentrated from four or five tons into one ton, and this is done cheaply, as it is a perfect milling ore. Last year the cost was about 95c. per ton, and the smelting a little more than \$6 per ton. As far as the development work goes this is one of the richest copper districts in America. Although not an old district, it is many times larger than the Butte district of Montana, which today is producing 28,000,000 lb. of copper monthly. Last year's run produced in the neighborhood of 3,000,000 lb. 99% pure copper. This was done without any railroad being built to the smelting works. With the completion of the railroad from Walcott to the smelting works, and with additional steam power, the output could be increased tenfold—so say the promoters of the enterprise. The company for the past 15 months has paid dividends at the rate of 6% on the issued capital of \$6,000,000. When the smelter is running with its increased capacity, the quarterly dividend should be at the rate of 12% per annum, and eventually, on completion of the improvements to be carried out with the new capital raised in Europe, the property, when running at full capacity, ought to pay 20 or 25% without any trouble whatever. As to the financial position, there were no loans from bankers, and, according to the audit made recently, it was shown that if all the company's moneys were received from the sale of copper, etc., there would be no liabilities whatever. The ore was not too heavy in sulphides; but it carried sulphur sufficient to be useful in the converters, and also a little iron which was good for fluxing purposes. All the ore in the district carried from \$2 to \$12 in gold, and from 1 to 3 oz. silver per ton. The president said they were induced to go into the copper industry in America by what has been done in the case of other companies; and in this connection he would read a few interesting figures as to what happened to those who had invested in copper in earlier days: £200 invested in Calumet & Pittsburgh in 1903 is now worth £10,000; £200 invested in Calumet & Arizona in 1902 is now worth £20,000; £200 invested in Greene Consolidated in 1901 is now worth £17,400; £200 invested in United Verde in 1897 is now worth £60,000; £200 invested in Wolverine in 1893 is now worth £10,000; £200 invested in Boston & Montana in 1896 is now worth £3,732.

As a fair comment on these enthusiastic statements, it might be asked what would the 400,000 shares of Penn-Wyoming Copper Co., now being placed in Europe, be worth

if the 1,200,000 shares already held in America were transferred to the London market.

According to the *Financial News*, the Fresno Copper Co. was registered in Edinburgh in 1902, with a capital of £400,000, of which, at the present time, 399,774 shares are issued and fully paid. The company was promoted by the vendors (the California Copper Syndicate, Ltd.), and the property, which is situated in Fresno county, California, was reported on by Messrs. Herbert Lang, W. J. Stoneham and H. V. Wheeler. It consists of some 2,500 acres of copper ground and a gold-quartz mine (acquired later). The consideration for the various properties acquired was £300,000, in fully paid shares. All the associations and connections of the company belong to Glasgow, and a quotation was obtained on the Stock Exchange of that city, and at the beginning of the present year there was a fairly firm market in the shares at par; but shortly after the turn of the year the price began to ease off, and it was rumored that the property was not up to the estimates which had been formed of it. At the beginning of last week the shares were quoted about 13s. to 13s. 6d. Some little time ago, in order to allay the anxiety of shareholders, it was determined to send out an independent expert, and Mr. Frederick Siebert was selected. Mr. Siebert's report condemns the property entirely. There was a scene of great excitement on 'change when the news became known, and heavy offerings of shares resulted in a sharp slump to 4s. 6d. It is feared that many small investors have been badly hit.

Mr. Percy F. Martin, who has been touring in Mexico on behalf of a London journal, is of opinion that the equipment of the Esperanza mine is as complete and thorough as could exist. Everything is of the very best possible quality, and yet not a penny is expended extravagantly. He says the fine mill, consisting of 120 stamps and 15 Huntington mills, the cyanide plant, the electric installation, and the whole of the buildings have been paid for. There are no other heavy expenses, other than those attendant upon the conduct and maintenance of the mine, in contemplation or necessary. The mine is regarded by its local management as a clean asset as it stands today, worth, from a most conservative point of view, 4½ times the amount of the subscribed capital, and probably a good deal more.

The Deep Leads water question has reached a most interesting stage. The problem of draining the river bed is now practically solved. It is reported that at Loddon Deep Leads they are the masters of the water. At Victorian Deep Leads hard by, the water will soon be under command. The stupendous nature of the task may be judged from the fact that at Loddon Deep Leads the pumping has been at the rate of 9,000,000 gal. per day, and at Victorian Deep Leads 6,000,000 gal. per day. Mr. C. Algernon Moreing, who has recently returned from a tour of inspection to the mines with which his firm is associated, states his confidence that as regards the gold contents of the wash, the geologists who have reported upon it have not been deceived. He reminded his hearers at a public meeting last week that the water once got out, the mine is dry and the water does not come in again.

A useful contribution to the eternal Chinese labor question is to be found in the proceedings at the last half-yearly meeting of the British North Borneo Co. The chairman, Sir Charles J. Jessel, told the shareholders that an interesting event occurred some two or three months ago, namely, the landing of 200 Chinese at Kudat. One of the things they most required at Borneo is population; and the population that is most readily at hand to inhabit and cultivate that country is the Chinese, and they had already, probably, about 15,000 Chinese in the country. They would like very much to have another 15,000 or even 30,000.

BUTTE, July 28.

Since shipping nearly all of its ore to the Washoe concentrator and smelter at Anaconda, the Red Metal Co. has been saving \$2 per ton on its output. The company figures on an average daily output of 1,500 tons for the next 12 months, which would give a total saving for the year of more than \$1,000,000. The old smelter of the Red Metal Co., which was acquired by the purchase of all the United Copper interests in Butte, is being rapidly dismantled. The

Red Metal Co. found the United Copper mines badly run down and poorly timbered, but they are being placed in first-class condition, and a higher grade of ore is being mined, though the tonnage has been temporarily reduced to about 1,300 tons per day. The company recently opened two new orebodies, one on the 1,200-ft. level of the Tramway mine, which is being worked through the West Colusa mine of the Boston & Montana Co., and the other on the 1,100-ft. level of the Minnie Healey. The extent of the latter is not yet known, as it was cut while a small drift was being driven. The vein is nearly 30 ft. wide, and about eight feet of it is rich, assays averaging 7% copper. As the ore deposits in the Minnie Healey have been pockety in the past, the company officials have not said much about the find, but development is proceeding to determine its extent. There is a belief among the company's engineers that the new orebody will be found to be a portion of the Leonard vein of the Boston & Montana Co. which pinched out near the eastern end of the Leonard claim, it being the opinion that the vein faulted at that point, and was thrown downward into the ground embraced within the Minnie Healey. Should this theory prove correct the new find would probably develop into one of the most important ever made in the Butte district, as the Leonard vein has been one of the richest and largest. The Tramway vein, however, has been opened for several hundred feet in length. The vein is eight feet wide and the ore high grade. The Red Metal Co. has also opened a new level in the Rarus at a depth of 1,500 ft., where mining is being done on what has been known as vein No. 16, which for years has been worked in the Mountain View by the Boston & Montana Co. The showing at this point is better than at any other place in the Rarus mine. The Red Metal is also opening the Berkeley mine through the old shaft on that property, and a portion of the Snohomish mine is being worked through it. Sinking is going on in both the Rarus and Corra mines, and the 1,600-ft. level in the latter is being opened, and 300 tons of ore are hoisted daily.—The Parrot Co. is mining for the Red Metal Co. on the Nipper vein at the 1,000-ft. level of the Parrot mine, and hoisting 50 tons of ore per day that runs 8% copper, while driving and raising on the vein, and in a week will hoist about 100 tons per day. The Parrot is also developing its own property on the 1,800-ft. level, where the ore is better than that mined on the level above, but not high grade, though there is a gradual improvement with depth. The company is hoisting about 400 tons per day of 3% ore.

The main shaft of the Mountain View mine, of the Boston & Montana Co., is still shut down and undergoing repairs, but hoisting to a limited extent is done through the air shaft. All the other mines of the Boston & Montana Co. are yielding the usual quantity of ore, about 3,500 tons per day, which is shipped to the company's smelter at Great Falls, together with about 200 tons of Red Metal ore.—The Anaconda Copper Co. has completed the three-compartment shaft of the Anaconda mine between the 2,200 and 2,400-ft. levels, and the company is now mining on the lowest level, which is also the lowest opening in the Butte district. The ore at that point is rich, a large portion of the vein assaying 8 to 12% copper, though the vein itself is not so wide as it is on the 2,200-ft. level.

The North Butte Mining Co. is mining on the 1,700-ft. level of the Jessie, which has developed into the best level in the mine. The ore-shoot is longer than on the 1,600 level, is richer and as wide. Very little second-class ore is being mined, the general average of the ore shipped being 7%. The company is now hoisting 1,000 tons per day, and the amount cannot be increased until a number of chutes are built. The North Butte Co. will soon begin driving a cross-cut north into the Berlin claim.

There is no prospect of an early resumption of operations by the Raven Mining Co. The Anaconda Co., which owns the Buffalo shaft through which the Raven Co. worked the Snoozer claim, has offered to hoist all ore that the Raven Co. can mine from the Snoozer, provided the mining is not done on the vein to the apex of which the Butte & Boston Co., an Amalgamated concern, lays claim. This precludes the Raven Co. from mining in the Snoozer because it is without funds to open the other vein in that ground.

Owing to the fact that there is such a great distance between levels in the Snoozer—400 ft.—there is much doubt as to the location of the apex of the vein on which the Raven Co. has been mining, many mining men familiar with the ground believing that the vein apexes in the Snoozer ground. It has been urged on Eastern stockholders that they raise the necessary money to open the Raven mine and also sink the old shaft on the Snoozer discovery vein to determine the apex question. The fact, however, that the Red Metal Co. owns one-seventh interest in the Snoozer, and has therefore the power to stop operations at any time is not encouraging to the stockholders to put up money for development. The Raven is developed to a depth of 700 ft., has a hoisting plant of its own, belongs to the Raven company, has a lot of payable silver ore in sight, and has disclosed the apex of a copper vein in the lower workings. The Butte officials of the Raven Co. have made a proposition to stockholders in the East that they raise the money necessary to carry on further development, but no favorable consideration has yet been given the suggestion.

At a depth of 200 ft. the Butte Hill Copper Co. has run a cross-cut north to the vein, which reached a distance of 110 ft. the past week and 80 ft. of it is in a vein, and the last assays taken show 15 oz. silver and half of one per cent copper per ton. The company has the vein of the North Star mine, which was formerly worked by Marcus Daly and yielded a great deal of silver. It is the vein that runs through the Colleen Bawn of the Butte & Bacorn Co., lying a short distance east of the Jessie S., the claim on which the Butte Hill Co. is working. The Butte & Bacorn Co. is developing the same vein, but will do no cross-cutting until a depth of 500 ft. is reached.

C. J. Adimi, for years foreman of the Gagnon mine at Butte, has become general manager of the gold properties of the Cable Consolidated Co., which has just started its own hoisting machinery and is increasing its output. The company has also begun exploration of its 400 acres of placer ground, and will bore 400 or 500 holes to bedrock to determine the value of the ground as a dredging proposition. Results so far are reported satisfactory.

The Pittsburgh & Montana Co., since it has abandoned its experimental smelter and is shipping ore to the Washoe smelter, is making a profit on its operations. There is a general denial on both sides of the story that Butte Coalition is negotiating for the purchase of the Pittsburgh & Montana property.—The Red Metal Co. has secured a transfer from United Copper interests of the Homestake mine, an outstanding interest in the Belmont, three-fourths of the Nora, and one-fourth each in the Canyon and Colleen Bawn claims, lying southeast of the city.

The Butte Copper Co., which is cross-cutting north from the Trifle shaft, at a depth of 300 ft., to get the north Anselmo vein, an extension of the Gagnon and Original vein, is putting up new surface machinery, including boilers, an air compressor, pumps and head-frame. As soon as it is up the company will sink the shaft several hundred feet deeper while mining the Anselmo vein.

PRESCOTT, July 28.

The building and successful operation of the 800-ton custom smelter by the Arizona Smelting Co. at Humboldt in Yavapai county, has given the mining industry in north-central Arizona new life, which in some sections would be called a boom. The company is receiving all the ore it can handle at present, and the management is considering plans for doubling the capacity of the plant.—Lawler & Wells have sold their copper property, on Copper creek, to a company which has 25 men on development work. This property contains one of the biggest low-grade copper deposits in Arizona. There is abundance of water power near by to drive all the necessary machinery of the mine and reduction works.—A. J. Pickerell has sold his Mineral Hill group of copper mines on the Bill Williams Fork to Chicago men. The new owners are now making preparations to erect a smelter of 200 tons daily capacity. A great amount of development work has been done on this property. Distance from railroad has heretofore kept it from the list of producers. The Arizona & California railroad is now building in this vicinity and will materially aid development of the district.

Fennell & Davis are unwatering the Last Chance mine near Prescott and will cross-cut to the vein from three levels in the 500-ft. shaft.—The Triangle Mines Co. has reached a depth of 350 ft. in the shaft on its property in Chaparral district, near the McCabe mine. The sulphide ore is rich in gold and the vein averages from three to five feet in width.

There has never been a time in the history of this part of Arizona when there was so much activity in the mining business as now. More miners are at work here today than ever before. Every district in the county is active, and money is seeking legitimate investment in the mining business. The big low-grade deposits of gold and copper are now, for the first time, receiving the attention they deserve. Lack of transportation facilities has, in some cases, been the great drawback to many properties but this will soon be remedied by railroads being built. Another serious obstacle was the lack of water for milling purposes. This, too, seems to have been overcome by unusual rains, supposed to be due to the filling of the Salton sink in California by the water of the Colorado river. The excessive heat in the Salton basin country results in great evaporation. Southwest winds carry this moisture over the higher altitudes of Arizona and Nevada where it is precipitated by the cooler atmosphere. Some have said off-hand that the filling of the Salton sink can have no possible effect on the climate of Arizona. The United States Government has kept a record of precipitation at Whipple Barracks, near Prescott, since the post was established in the '60s, and the annual rainfall has averaged between six and eight inches. Last year the rainfall reached 40 in. and this year it promises to be even greater than this. Water is abundant everywhere. A country cannot be called arid that has such a large precipitation. If the Salton sea is not causing this great rainfall in this part of Arizona, I would like to ask some of the eminent weather observers what has caused it? Anyhow, the railroads are being built, the water is here in abundance, and the big low-grade deposits of gold and copper ore are being investigated by individuals and corporations seeking large, safe investments.

CALUMET, Aug. 1.

An abstract from the annual report of the Calumet & Hecla Mining Co. for the fiscal year ending April 30 is given herewith:

ASSETS.			
	1906.	1905.	1904.
Cash at mine	\$ 120,257	\$ 133,047	\$ 116,917
Cash at New York	15,000	15,000	15,000
Cash at Boston	7,817,994	16,496,133	15,939,001
Development & equipment fund	1,827,544		
Insurance fund	990,858	927,034	757,691
Bills receivable	1,140,122	590,213	451,521
Employees aid fund	4,906	10,991	6,208
Total	11,916,681	88,172,418	87,286,338
LIABILITIES.			
Drafts in transit	\$ 38,481	\$111,668	\$ 67,682
Bills payable	370,381	313,560	305,617
Mill machinery	878,000	603,000	330,000
Total	\$1,286,862	\$1,028,228	\$703,299
Balance	\$10,629,819	\$7,144,189	\$6,583,039

*Including copper at 18c. per lb. and mineral at 7c. per pound.
 †Including copper at 15c. per lb. and mineral at 6c. per pound.
 ‡Including exchange loans receivable, copper at 13c. per lb. and mineral at 5c. per pound.

President Agassiz says: During the past year we produced mineral equal to 43,652 tons of refined copper, as against 43,090 tons last year. Our product of refined copper was 50,526 tons; for the previous year our product of refined copper was 42,822 tons. The price of copper has varied from 15½ to 19c. per lb. It is now about 18¾ cents.

There have been paid during the past year two dividends of \$15 each and two of \$10.

Since last May we have remodeled six of the Hecla mill stamps so that we now have 23 modern stamps in commission. We have already started remodeling the remaining five old heads to treat amygdaloid rock and hope to have them in commission by May 1, 1907. They will have a capacity of 3,000 tons daily.

The Calumet mill, as remodeled, has run most satisfactorily during the past year. The value of copper saved each year by the new system of stamping and washing has thus far practically equalled the cost of reconstruction of the mill. A great part of the mill-trestle connecting the bins with the railroad has been filled in. This work will be continued

whenever practicable. The warehouse at the lake has been moved to a new location on the extension of the coal-docks.

We have continued our experiments upon the tailing from our mill and hope soon to make plans for the erection of a mill intended to save a good part of the fine copper we are now losing.

The addition to the electric power-house at Torch lake has been completed. Two of the large hoisting engines built for mining the Osceola lode have been erected there, so that we now have in our power-house a capacity of 9,000 h.p.; the building is large enough to allow the erection there of the third Osceola hoisting engine when needed, adding about 30% to our available horsepower.

At the Lake Linden smelting works we have remodeled the laboratory to meet the growing demands of the smelter and mills. It will be necessary during the coming summer to rebuild our cupola furnace, remodel five of the remaining furnaces and build a new mineral house at a total cost of about \$105,000.

At the Buffalo smelting works, we have rebuilt one of our furnaces and installed two waste-heat boilers. The whole of our plant is now run by electric motors, power being supplied by means of the generator in the central boiler-plant at our electrolytic works.

The stockholders of this company passed a vote at the last annual meeting authorizing the directors to avail themselves of a law recently passed by the Michigan Legislature, permitting mining companies, if authorized by a vote of their directors, to subscribe for, purchase and be interested in the stock of any other company formed for mining, smelting or manufacturing wholly or at any place other than in the State of Michigan. This statute provides a simple and effective method for the rapid development of the mineral lands of the upper peninsula of Michigan; lands, many of which have remained undeveloped for want of capital from the earliest date of copper mining in the State. Under this vote, and in accordance with the statute, we have organized, under the laws of Michigan, the Manitou Mining Co., of which we own nine-tenths of the stock. The territory controlled by this company amounts to 38,693.55 acres. The Frontenac Copper Co. has also been organized, under the laws of Michigan, to hold the mineral and other lands we purchased from the Central Mining Co., the Manice lands and other tracts in Kekeenaw county. The territory owned by the Frontenac Copper Co. covers 22,268.50 acres; we hold the whole stock of this company. We are exploring, with diamond-drills, a part of the lands of the Frontenac and Manitou companies to fix the position of the various copper-bearing lodes which cross them. On the Delaware property (now Manitou) we are drifting from the bottom of a shaft 100 ft. deep on the Montreal amygdaloid; the showing of copper in this vein is fair. We have located thus far the Calumet conglomerate, the Osceola amygdaloid and the Kearsarge conglomerate on this property. We have continued active exploration of the Superior mine, of which we hold the option on 51% of the stock until August 31, 1906. We have secured an extension of this option until December 31, 1906, and hope by that time to have sufficient information as to its probable value to come to a decision regarding it. We have spent thus far \$42,000 in exploring that property. The Superior has 400 acres. For \$25,000 we have secured an option on the Nonesuch mine in Ontonagon county, which expires in June, 1907. The payment was based upon preliminary tests of milling the rock from the copper-bearing belt of that name. The Nonesuch has 640 acres. We have obtained an option on a majority of the shares of the Gratiot Mining Co., organized under the laws of Maine. The mine is on the extension of the Kearsarge lode, north of the Mohawk; it has a probable length on the line of the Kearsarge lode of 5,960 ft. to a depth on the slope of 2,540 ft. The Gratiot has 600 acres. We have taken an option on the land of the New Jersey Mining Co., which runs for two years, and contains 720 acres on the mineral belt and 1,540 acres south of Lac La Belle. We have taken options on other parcels of land containing approximately 2,000 acres on the mineral belt, which are more or less surrounded by the present holdings of the Manitou and Frontenac companies. We have also taken options on 51% of the stock of the Caldwell Copper Co. and of the La Salle Copper Co.,

both having two years to run. The Caldwell Copper Co. controls 520 acres and the La Salle Copper Co. 840 acres next to the property of the Tecumseh Mining Co. We have paid for the lands of the Frontenac Copper Co. and the Manitou Mining Co. \$704,964; for exploration on the Superior, \$42,000; for an option on the New Jersey, \$10,000; and for an option on the Nonesuch, \$25,000. Should we exercise our options for the purchase of the New Jersey, Nonesuch; and the control of the Superior, Caldwell, La Salle, Gratiot and other options, there remains to be paid \$1,555,000.

The purchase of some of these properties has given us a large supply of timber, and we hope in time to find producing mines which may materially add to the output of the Calumet & Hecla proper. For these purchases and their development the directors have laid aside, as a development fund, the sum of \$2,000,000, which has been increased by \$750,000 since April 30, 1906.

It will be seen by this report and the statement of assets and liabilities that during the past year we have spent large sums for the purchase of new properties and planned for the expenditure of important sums to develop them. Large outlays will also be made during the coming year at the smelting works and shops, in equipping the Hecla & Torch Lake Railroad and in broadening its gauge, in remodeling a part of the Hecla mill, in duplicating our water supply from the Lake Superior station, in erecting a foundry, completing the electric power plant and distributing electric power. All this is needed to carry on the mine with economy while working on its present scale.

CRIPPLE CREEK, July 30.

The original plan of driving a deep drainage adit to unwater the district has been practically abandoned, and a scheme is now on foot for a new drainage tunnel, known as the intermediate tunnel, which will not be so deep by about 350 ft., will cost less, and be completed more quickly than the original. It is estimated that the new adit will only take 18 to 20 months as against three years, and cost about \$200,000 less than the deeper 'tunnel' first proposed. This scheme is finding more favor with the mining companies. It is proposed to use the water from the adit for power purposes.

Grant & Co., operating on the Pike's Peak of the Stratton Estate, on Bull hill, made a shipment of sacked ore to the Eagle sampler on the 24th inst. This ore was obtained from the 300-ft. level where a rich narrow streak is being mined. Assays as high as 15 oz. per ton have been obtained from this sacked ore.—The second consignment this month of about 200 tons of low-grade ore from the Ramona lease of Hembie & Co. is being hauled to the Ironclad cyanide mill. The ore averages about \$8 per ton and is mined at a depth of 200 ft. A similar shipment is also being made to the Ironclad mill from the War Eagles on Bull hill by Hervey & Darnell, lessees.

The three samplers of the district, the Eagle, Taylor & Brunton and the Cripple Creek Sampling & Ore Co., have raised the rates for sampling ore, which they buy, from 60c. per ton to \$1 per ton. Ore which is only sampled in transit will still be charged for at the old rate of 60c. The reason for this raise is said by the samplers to be their inability to make enough profit under the old rates.—The extensive alterations to the old Telluride mill, at Colorado City, are nearing completion and it will soon be in condition to handle the output of the Golden Cycle mine on Bull hill and also a portion of the Findley ore. The mill will have a capacity of about 200 tons per day and is expected to be running by October 1.

Becker & Travell, operating a lease on the northern part of the Granite property on Battle mountain, have sunk the Cody shaft to a depth of 125 ft. At the bottom of the shaft is a strong vein which is supposed to be a continuation of the Independence vein, which, on the Portland Co.'s ground, is known as the West Bobtail.—An average of three cars of ore per day is being shipped by the Isabella mine on the north slope of Bull hill. The ore is being mined by the company and about thirty sets of lessees.—The Etna Development Co., leasing the Index mine on Gold hill, started work today. Two drills will be put to work, one on the cross-cut which was previously being

driven at a depth of 465 ft., known as the third level, and the other on ore at the bottom of the 700-ft. level. Sub-lessees Swanson and Martinson, operating on the 700-ft. level of this mine, shipped a car of ore last week which ran \$42 per ton.

The American Eagles mine, one of the largest properties of the Stratton Estate, situated on Bull hill, is closed down. It has been under lease for the last 18 months to Cox & Durbin and associates, who have been paying to the trustees of Stratton Estate 25% flat royalty on all ores shipped. J. H. S. Cox has applied to have this royalty reduced, as he claims that the royalty is too high when the cost of running the large top plant of machinery is taken into consideration.

SALT LAKE, July 28.

The sensation of the week in Utah mining circles has been developments in the coal land cases. As yet, no criminal action has been started, but the Government is plaintiff in four civil actions filed in the Federal court in this city. The defendants are the Utah Fuel Co. and the Pleasant Valley Coal Co., both of which are charged with fraud, deception and conspiracy, in obtaining possession of between 20,000 and 30,000 acres of coal land. There are two actions against each of the defendants, under distinct classifications. One class deals exclusively with lands that have been acquired from the State of Utah through its land board, while the other has reference to lands that have been acquired direct from the Government under the coal-land laws of 1873. It is charged, with regard to the last named law, that individuals in the employ of the company filed on quarter-sections of land, which they deeded to either of the defendants for a consideration, contrary to the purposes of said law. The suits were filed in the name of William H. Moody, Attorney-General of the United States. The land in question is in Carbon county. The Government seeks to have title to these lands vacated and proposes to sue for the value of the coal extracted therefrom. A number of prominent citizens of the State are involved, and it is not improbable that criminal actions will follow, although officials of the Government are concealing this part of the program. Among those accused of being active in the alleged conspiracy are William F. Colton, president and treasurer of the Pleasant Valley Coal Co., Robert Forrester, geologist, of the Utah Fuel and Pleasant Valley Coal companies, H. G. Williams, manager of the first-named company, William H. Bird (deceased), attorney for both companies, Royal C. Peabody, of Boston, an official of the Pleasant Valley Coal Co., Charles M. Owen, a civil engineer, and others. The members of a former State land board, of which ex-Governor Heber M. Wells was president and Byron Groo secretary, were severely criticised for gross negligence. Special agents of the Government have been working on the cases for more than a year, and it is said other actions are likely to follow.

In Bingham district the Utah Copper Co. will begin stripping overburden with steam-shovel within a few days. All of the equipment for the Utah Apex aerial tramway has arrived at Bingham and work on the terminals will begin next week. Construction of the new compressor building will also be started. The tramway will be 2,500 ft. long.—The new compressor plant at the New England Gold & Copper Co.'s mine, at Bingham, is in service.—At the Montezuma mine, at Bingham, a 12-in. vein of high-grade lead ore has been encountered in a drift south from the shaft on the 200 level; there is ore in the north drift and another fissure has been found in a cross-cut west from the shaft. Shipments will be made soon.

At Alta an important strike has been made in a cross-cut west from the adit level of the Columbus Consolidated mine, where a contact-vein has been encountered showing shipping ore, which assays 30 to 40% lead, 40 oz. silver and 3% copper. The find is 1,500 ft. from the developed portion of the mine. The vein has been followed for 30 ft. and shows a width of seven feet.

W. A. Clark, president of the San Pedro, Los Angeles & Salt Lake Railroad, states that he has given orders for the survey of a line of railroad into the Deep Creek mining district. Salt Lake business men are seeking a more direct

route to Ely, Nevada, and one that will tap the Deep Creek camps as well.

Ore shipments from the Tintic district last week aggregated 147 carloads, the contributing mines and amounts being: Ajax, 2; Carisa, 6; Centennial-Eureka, 42; Beck Tunnel, 7; Black Jack, 8; Bullion-Beck, 6; Dragon Iron, 9; Eureka Hill, 3; Eagle & Blue Bell, 3; Gemini, 3; Grand Central, 6; Godiva (concentrate), 2; Mammoth, 21; May Day, 3; Ridge & Valley, 2; Scranton, 4; Swansea, 3; So. Swansea, 1; Uncle Sam, 2; Uncle Sam (concentrate), 2; Victoria, 6; Yankee, 4.—A new wage schedule goes into effect in the Tintic district August 1. Single-hand men are to get \$3 per day, machine helpers \$3, and muckers, \$2.50.

JOHANNESBURG, July 2.

The reduction of the cost of living on the Rand was one of the results expected after the war. The failure to cheapen the living expenses and to lessen the cost of production is very apparent. After four years of British control, the Transvaal is no better off, in regard to costs, than under the Kruger regime. Today the married artisan finds it impossible to keep himself and family on less than £26 per month. A recent conference was held to consider tariffs, etc. The other colonies of South Africa have benefited at the expense of the Transvaal. More burdens are imposed on this colony, and as the tax falls on foodstuffs, the very poor will be the chief sufferers. Already the cost of much mining material and of foodstuffs has risen. The fact of the matter is that mining is almost the only taxable industry in South Africa. It is felt here that the De Beers Diamond Co., at Kimberley, has not borne its fair burden of taxation, and that the Rand is to be bled still more, in order that Kimberley may escape. Critics should remember the enormous burden in taxation that the Rand has to bear, when they find fault with the high mining costs prevailing here. There are few industries in the world that are taxed as heavily as the mines of the Rand. Not only is there the direct tax of 10% on profit, but there is the indirect taxation which amounts to much more. Take the railroads, for instance, which are owned by the Government and are run for revenue. The rates prevailing are exorbitant. A ton of coal at the Middleburg mines is sold for 6s. per ton. The railroad charges 10s. per ton to deliver this coal to a mine on the west Rand. It costs no more to send a ship-load of timber from San Francisco to New York, load it onto a steamer and send it all the way to Durban, than it costs to unload the same timber and send it to Johannesburg. With such conditions, how is it possible to show low working costs on a mine?

The behavior of the coolies over the much talked of poster has been a surprise to everyone. The best informed people thought that at least 1,000 Chinamen would take advantage of the offer of the Liberal party and go back to China. Up to date, 12 men out of 50,000 have asked to go back! What a vindication for the people of the Rand, after the campaign of lies and calumnies of the Liberal party! It is now feared that the Liberal party, out of a feeling of sheer pique, will frame another poster and almost force the coolies to go home. It has now been proved beyond the shadow of a doubt that the coolies are quite contented with the Rand, and do not want to go home. They have never been in better circumstances in their lives.

There has been much comment on the high death-rate from accidents prevailing on the mines of the Rand. It is the highest in the world, and has been going steadily up. At the present it is about 6.69 per 1,000 per annum. The death-rate of the white employees is about 4.4 per 1,000 per annum. Compared with 1.5, the rate prevailing in the mines of Great Britain, these figures are appalling.

The main reason for the high death-rate on the Rand is the class of labor we have to deal with. When a mine is worked by raw Chinese or Kaffirs, who have no mining sense, it is almost impossible to prevent accidents. They have a way of getting into dangerous places, and doing what they should not do. Sometimes the action of one coolie or Kaffir endangers the lives of many men, as in a blasting accident. Fall of rock and blasting accidents cause the greatest number of deaths on the mines. Raw coolies and Kaffirs have a way of treating dynamite and detonators with scant respect, until one or two of them are blown up.

On one mine quite a novel method was recently adopted, to impress a new batch of Chinese with the dangers of explosives. All the coolies who had been maimed by mine explosions were paraded before the newcomers. At the same time one or two interpreters walked among the new coolies with a few detonators, fuse and dynamite, and warned them of the danger of fooling with these instruments of the evil one. So far none of these coolies have been injured by explosives.

TORONTO, July 27.

The increased importance of the Canadian mining industry is shown by the reports of the foreign trade of the Dominion for the fiscal year ending June 30, a summary of which has just been published. Exports of products of the mines show a total value of \$35,469,631, as against \$31,932,329 for the previous year.

A branch mining record office has been opened at Cobalt in response to the appeals of the miners and prospectors for better facilities for recording claims; T. A. McArthur is in charge. M. B. Baker has been appointed assistant inspector of the division.—An important discovery has been made on the Gillies timber limit, adjoining the Cobalt area on the south, now being prospected for the Provincial Government by a party under the direction of Willet G. Miller, Provincial Geologist. A vein of smaltite, or arsenide of cobalt, has been found six inches in width, at a depth of three or four feet below the surface. The find is regarded as of great value. The vein is to be stripped for examination. The exploration party will be joined by E. T. Corkill, Provincial Inspector of Mines, next week.—Several prominent mining men and financiers have visited Cobalt lately with a view to investment. Among the number are John McKane and John J. Adams, of New York, representing the Schwab interests, H. M. Whitney, of Boston, and William G. Thomas, of Quebec.

At the Nipissing mines, at Cobalt, several new strikes are reported. The outcropping of a rich smaltite vein shows a lump weighing 250 lb. Ledge 26, which at first showed a narrow vein, widened steadily as it was followed downward, and now at 60 ft. discloses a rich vein 7 to 10 in. wide. It is being cut in a northerly direction and the large mass above noted was found near its northern extension. A third vein apparently runs to a point of junction with these two and a shaft is being sunk, from which drifts will be run into all three at about the 80-ft. level. The value of the output of Ledge 26 since it was opened last fall amounts to over \$250,000.—A find of pure silver has been made on the Gates property, at Clear lake, at a depth of 45 ft.—Six miners have been arrested for stealing ore from Cobalt mines and disposing of it to jewelers and makers of souvenirs, such as fancy pins, etc. The thefts had been suspected for some time and the Mine Owners' Association employed private detectives, who discovered that ore to the value of thousands of dollars had been stolen and disposed of at Toronto.

Numbers of prospectors continue to leave the Cobalt area for the Lake Opastica gold region. Little further information is obtainable as to the actual value of the finds in that quarter. While there is no doubt that gold exists there in appreciable quantities, its occurrence over any considerable area in a commercially valuable form is regarded as an open question. Thomas W. Gibson, Deputy Minister of Mines for Ontario, states that as scarcely any development work has been done, any estimate of the value of the new field is premature. He is of the opinion, however, that for the most part the mineral deposits are of low-grade ore.

The iron mines at Ironsides, near Hull, Quebec, which have not been worked for 25 years, are being subjected to tests with diamond-drills, borings being made to a depth of 400 ft. to ascertain their possibilities. American capitalists are interesting themselves in the result, with a view to establishing electric smelters should a supply of the raw material from this source be available.—A find of radioactive mineral is reported near Murray bay, Quebec Province. Samples have been sent to Paris by A. J. Lippens and H. M. Lippens, members of a mining syndicate who made the discovery. A. Fieux, a French mining expert who has been experimenting with it, asserts that it exists in paying quantities.

Thomas G. Blackstock died in Toronto on July 24 from

bright's disease, aged 54 years. He was prominent in legal and financial circles and, in connection with his late father-in-law George Gooderham, he was largely interested in the War Eagle and Centre Star gold mines at Rossland, B. C., and in the St. Eugene mine. He had been in ill health for several years. A widow and seven children survive him. —G. A. Guess, graduate of the Queen's School of Mining, Kingston, Ont., has been appointed superintendent of the reduction department for the Greene Consolidated Copper Co. at Cananea, Mex. —F. J. Lee, of Helena, Mont., who has just returned from a visit to the Yukon district, expresses the opinion that Hatfield, the rain maker, has not been fairly treated in being refused the sum agreed upon in case of an increase in the water supply. He states that on Dominion creek, with a watershed of 45 miles square, the increase in the rainfall has been fully 500%, every one having water enough, whereas last season work had to be suspended on account of drought. Mr. Lee states that the difficulty as regards water is owing to the mistake of the miners in sluicing from inadequate watersheds, the supply from which would be insufficient even in unusually wet seasons.

DENVER, July 29.

Following one of its most disastrous winters, the San Juan country is now enjoying a high degree of prosperity. New enterprises, requiring large outlays of money, are assured, the money having been secured before the debris of the storms was cleared away. Lake, Clear Creek, Gilpin, Summit and all the prominent older mining counties are daily adding to their productive areas, opening up new bodies of ore in old mines and finding pay-shoots in heretofore undeveloped ground, forcing the conclusion that the best opportunities are still in the old mining districts, especially in properties that have produced in the past, but from one cause or another have been idle for a time. Capital from outside the State is largely interested in these developments. If any one part of Colorado is suffering for lack of capital, at least one of the reasons is disregard, in the past, of the rights and interests of the investor. It is no excuse to say that other sections are reaping a harvest from similar dishonest methods. The apparent prosperity is temporary and the day of reckoning inevitable; each district must pay the price of a bad reputation.

For more than 25 years the gulches of the Mosquito range have been prospected for the extension of the Leadville gold belt. W. P. Dewey and associates, owning ground in Big English gulch, have been prospecting about seven miles north of the Ibex mine. The Dewey property was taken over by the Bug Gold Mining Co. and a lease of part of the ground made to James Robinson, who is operating under the name of the J. B. Robinson Leasing & Mining Co. The country is traversed by a large porphyry dike. Robinson drove an adit in the dike about 100 ft. and has encountered a body of ore, which gives promise of great extent. The ore is a sulphide carrying 3 to 6% copper and as high as 5 oz. gold and 20 oz. silver per ton. The shoot is said to be of the Leadville blanket type and there is some local excitement over the discovery.

Prospecting by diamond-drill through the Yak adit, by drilling the ground at intervals of 100 ft. over an extent of 1,500 ft., is believed to have demonstrated the existence of ore nearly 100 ft. thick lying in a lower contact. The company has not given out any information concerning the result of its exploration, but it is generally believed that the ore was found in a contact plane lying 300 to 500 ft. below the floor of the Yak adit and on the trend of the Silver Cord ore-shoot. The Silver Cord winze will be continued 300 ft. to the new find, giving it a total depth of 600 feet.

The Japan-Flora group of mines, in San Miguel county, which has been under working option for several years past to A. G. Brownlee and associates, has been transferred to the Japan-Flora Mines Co. The company is composed of Philadelphia capitalists with Col. Brownlee, of Denver, who is the general manager. The property consists of the original Japan-Flora group, the Ajax group and the Valley View group. For a number of years the course of the Smuggler-Union vein southeast was in doubt. I believe it was the late Arthur Collins, manager of the Smuggler-Union, who identified the Ajax vein as the continuation of the Smuggler-

Union. The Japan-Flora Mines Co. is credited with having spent about \$250,000 in development work under its option, uncovering large bodies of milling ore. The company is now planning the erection of suitable reduction works.

The activity in San Juan county is spreading. Poughkeepsie gulch, long neglected, because of its extremely difficult conditions, brings forth the most sensational gold strike of the season. A large vein of quartz carrying a high-grade gold vein, about one foot wide, has been found by J. W. McDonald near the old Letcher property. Four samples of the streak assayed, respectively, 4 oz., 15 oz., 32 oz. and 155 oz. gold per ton. —Red Mountain, in Ouray and San Juan counties, is an active camp. Under the persistent drainage scheme planned by George Crawford, large bodies of ore have been made available for extraction and plans are being arranged to re-open such old-time producers as the Yankee Girl and Guston mines. —A strike of high-grade silver ore in the Big Bend group of mines, on Saxon mountain, in Clear Creek county, is causing local excitement. The ore is described as a carbonate carrying 1,000 to over 20,000 oz. silver per ton in a streak eight inches thick, containing native silver and silver glance. The find was made in a new location, in one of the oldest mining districts in the State. —Cincinnati and Denver parties, incorporated under the name of the International Mining, Milling & Smelting Co., have closed a deal for property on Columbia and Democrat mountains in Clear Creek county, including the Clay-pool tunnel, an adit 1,150 feet long.

BISBEE, July 30.

The Holbrook shaft of the Copper Queen Consolidated Mining Co., which had been settling for some time past, finally caved on Monday last. The shaft has been filled with waste from the 100-ft. level to the surface, to prevent more damage. As soon as the ground ceases settling, the work of repairing the shaft will be commenced. At the Copper Queen, the mains are being laid to distribute compressed air to the different shafts for operation of the air-hammer drills, a large number of which have been purchased. They will be used in the hard stopes. At the Copper Queen smelter, furnace No. 9 has been finished, and will soon be blown in. The scaffolding for the new smoke stack is nearing completion. The material for the new reverberatory furnace has arrived, and construction will be commenced at once. At the Calumet & Arizona, things are going along about the same as usual, with no important changes. —At the Shattuck-Arizona the 600, 700 and 800-ft. levels are being developed. On the 600, the drift is in vein-matter and iron ore. On the 700, two high-grade orebodies have been encountered; one is oxide and the other is sulphide. On the 800, the drift is in low-grade sulphide, and two raises are being cut to the 700. In the shaft a new air-line is being installed, as well as a new water-column. On the surface the new steel head-frame is being erected, and orebins and tramway are being rushed to completion, the cables for the tramway having arrived. The new change-house will be occupied on Monday. The railroad company is building a spur for the accommodation of the Shattuck. —At the Denn-Arizona the drift is still in silicious iron ore. It is the intention to connect with Saginaw, and intercept the drill-bore. In the shaft also, iron ore has been encountered, and the management is confident that this is the fore-runner of a large body of copper ore. The stations for the pumps have been completed. The water remains about the same. —At the Cochise the shaft has been sunk to a depth of 630 ft. and is in decomposed porphyry. The drift on the 315-ft. level has been driven 680 ft. and several small orebodies have been encountered, but it is not expected to reach the main orebody in less than 125 ft. more. The first which will be encountered will probably be the extension of that found by the Copper Queen, on the 1,200-ft. level of the Czar shaft. There have been many improvements made on the surface, the principal one being the installation of a new 150-h.p. boiler. —At Tombstone additional boilers and engines are ready to begin again unwatering the mines. At present the pumps are lifting 4,000,000 gal. of water per diem which, with the new equipment, will be greatly increased. The Tombstone mines are now shipping 25 cars of ore per week to the smelters at El Paso.

Mining Summary.

ARIZONA.

GRAHAM COUNTY.

(Special Correspondence).—The Mogollon Mountain Coal Co. has been organized at Safford, and plans have been perfected for the location and development of coal lands recently discovered in the Mogollon mountains of New Mexico, about 45 miles from the Arizona line. Twelve directors were elected as follows: George A. Olney, Z. C. Prina, John J. Birdno, Lee N. Stratton, John W. Casteel, Jos. McKinney, Wm. Robertson, Y. Huston, W. B. Funda, Peter Andersen, Thos. Cunningham and Nathaniel Wanslee. Mr. Cunningham was elected superintendent and general manager.—The directors of the Home Copper Co. met this week to hear a verbal report of the superintendent—N. L. Jenkins—concerning development work. Mr. Jenkins stated that the new whim is now in operation and the water has been bailed out of the main shaft, in which sinking will now be continued. This company is in better shape than heretofore, and development work is in progress.—While grading to move the hoist from the wagon-road to the shaft at the Gold Belt Development & Reduction Co.'s property last week, a strike was made 300 ft. from the shaft, where a vein two feet wide was uncovered. It is specked with free gold, and had been covered up by the wash.—N. C. Lewis, of Clifton, is working on the timber construction for the hoist which is nearly ready for use. It is the intention to run by August 1.—A report has just reached here of a cave in the Coronado mine, a property of the Arizona Copper Co., situated two miles above Metcalf, in which three miners—one American and two Mexicans—were entombed. No details have yet been obtained.—Frank McLean, foreman of the West Yankee mine (a Detroit Copper Co. property), has gone to the Pacific coast to spend a month.—Frank D. Rathburn, of the Detroit Copper Co. mine office, has been placed in charge of the development work now being done at the Santa Rosa mine by the Detroit Copper Co.—George H. Booth, mechanical draughtsman for the Detroit Copper Co., has been temporarily transferred to Globe to do some special drawing for Mr. L. D. Ricketts, of the Old Dominion Copper Co. It will take two weeks to complete the work.

Morenci, July 28.

CALIFORNIA.

AMADOR COUNTY.

It is reported at Jackson that W. F. Detert will sink a deep shaft on the property known as the Hoffman field, situated south of the Argonaut and Muldoon mines, near Jackson, to work on an ore-shoot discovered at a depth of 1,200 ft. by means of a level run south 1,900 ft. through the Argonaut property.

BUTTE COUNTY.

The Southern Cross at Enterprise has been closed, owing, it is said, to the financial stringency caused by the burning of San Francisco. Algernon Del Mar is superintendent.

DEL NORTE COUNTY.

(Special Correspondence).—W. H. H. McCutcheon and associates on Myrtle creek are preparing to work their property on a much larger scale, having acquired the Wagner and other water-rights. They are so much encouraged by the showing made in their prospects that they will put on men preparing for the next winter's work.—L. T. Hendricks and Percy Blake left the first of the week with tools and provisions to examine their Preston Peak property, a large silver and gold proposition, and if the value of the ore is sufficient to overcome the expense of mining and transportation, the mine will be equipped.—On August 20 the Elkhorn mining property will be sold to satisfy a judgment rendered July 28. It is reported that if satisfactory arrangements can be made, parties are ready to take the property and resume operations without delay.

Crescent City, July 28.

EL DORADO COUNTY.

(Special Correspondence).—The Havillah mine, at Nashville, after two and one-half years' operation, has been closed down, the management apparently being unable to make

the venture profitable. The main shaft was sunk to 1,200 ft., and a drift run south 500 ft., and one north 1,600 ft., into the Montezuma ground adjoining, where a short shoot of ore was encountered. Although the mine was well equipped with hoisting machinery, enough ore could not be broken, or, at least, hoisted, to keep the 20-stamp mill in operation. Prior to this last effort to work the Havillah mine, the property had been idle for many years, although it was one of the earliest quartz mines in California to be worked, and one of the first, if not the first, to have a stamp-mill.

Nashville, July 28.

(Special Correspondence).—At the Fort Jim mine, six miles from Placerville, Philip S. Baker has an adit 600 ft. in the gravel, which he is running through a roller-mill.—White & Richards are prospecting with a Keystone drill, 2½ miles from Newtown.—About five miles above Fairplay, F. M. Phelps is driving to intersect an ancient channel, on which he owns 900 acres. The drills are run by water-power.

Placerville, July 23.

INYO COUNTY.

It is reported that the Ratcliff mine, at Ballarat, in Panamint district, is under option to Salt Lake mining men who propose to re-open it. This property has been idle for several years, having been closed down by creditors under foreclosure of mortgage. The mine is equipped with a 20-stamp mill and a pipe-line conveying water from Stone Corral three miles distant.—According to press reports, terrible heat conditions prevail in the goldfields of Inyo county, and several lives have been lost. Mr. W. H. Adams, a mining engineer, who has just returned to Los Angeles from Panamint, says that eight prospectors were brought in dead from the heat while he was in that region. During his stay at Panamint six bodies were brought there, all victims of sunstroke. The heat, he says, is terrible and unabated day or night. At Ballarat, he relates, the thermometer registered 135 deg. at noon, and at midnight following, had dropped to only 116 deg., which was the average for three days. In the desert section lying south of Redlands, he says, the mercury went up to 160 deg. and could record no higher.

NEVADA COUNTY.

The Delhi Co. has purchased the large Reidler steam pump that was formerly in use at the Allison Ranch mine, below Grass Valley, for use in the Delhi mine, above Columbia Hill.—The grading for the 20-stamp at the Prescott hill shaft of the Sultana group, is completed and the building of concrete foundations is nearly finished. The mortar blocks will be of concrete.

Work on the Pennsylvania and W. Y. O. D. mines at Grass Valley has been temporarily suspended, owing to bad air in the workings.

SAN BERNARDINO COUNTY.

The Arizona-Mexican Mining & Smelting Co. received the past week seven cars of concentrate from the Humboldt Smelter at Needles. The yard is filling rapidly with ore received. The roaster is handling 30 tons of concentrate per day. The first carload of copper ore from the Valley Wells property, recently purchased by the company, is now on the way and teams are hauling more to the railroad. The company expects to start up the lead stack about August 15. The copper stack is being erected as rapidly as possible.

(Special Correspondence).—The Trojan Mining Co., having leased from the Bonanza King Development Co. its mine (the Bonanza King), in Providence mountains, has begun erection of a 10-stamp combination silver mill and expects in the near future to install 10 more stamps. The old workings proved to have a great deal of available ore, as the company that operated the property 20 years ago, and which only discontinued operations when its mill was destroyed by fire, worked little ore that would go less than 40 oz. silver. It is the purpose of the new company to sink below the sixth level, which is at 460 ft. The mill was installed under contract by Elliott & Drescher, of Prescott, Ariz. Power is furnished throughout the mill and pumping stations (except the hoist, which is steam) by distillate engines, of the Western Gas Engine Co. of Los Angeles. The old dumps are estimated to contain 225,000 tons. E. J.

De Lano, former superintendent, having resigned, A. M. Rockwell, late superintendent of the White Gold Mining Co., has assumed charge of the mine and mill, and is at present working 75 men, expecting to increase this force when accommodations can be provided.

Fenner, July 28.

SHASTA COUNTY.

The buildings which at one time constituted the smelter town of Keswick are being torn down and moved to be re-constructed at the new copper town, Coram.

TUOLUMNE COUNTY.

The properties of the Rawhide Gold Mining Co. have been assigned to George W. Ade, as trustee, for the benefit of numerous creditors. Ade is to manage the business, and whenever the indebtedness shall be paid the trust terminates. Mr. Ade was formerly manager of the Copper King Mining Co., in Fresno county. All of the employees of the App mine, at Quartz, have been paid. On the tenth day of each month hereafter, employees will be paid by draft. The company boarding-house in Quartz has been discontinued and employees will hereafter board and lodge wherever they choose. At present but 40 stamps are dropping in the App mill, but the entire 60 stamps will soon be in operation.—The Atlas mine, near Tuttletown, has been unwatered, the shaft cleaned and straightened, and sinking is in progress. At this mine can be seen the most unique head-frame in the State. It is a pine tree 18 in. diam., to which the sheave wheel is attached. The cable runs from the engine to the wheel, then turns and runs at right angles down the shaft.—A cave occurred last week in the Patterson mine, near Tuttletown, imprisoning Peter Johnson and Andrew Knudsen for a time. They were rescued by Mr. Davies, the superintendent. The work of cleaning out the south drift of the Patterson is progressing. They are in about 400 ft. Between there and the face of the drift a winze 70 ft. in depth was sunk 35 years ago, which will be cleaned out and prospected. Should the company decide to use the old shaft, pumps will be installed.

(Special Correspondence).—The Golden Rock ditch, built 25 years ago for mining purposes, but never used, is being cleaned out and repaired to supply water to the mines in the vicinity of Groveland. The work is well under way and will be finished before summer is over.—The company which has built an electric plant on the Tuolumne river will soon be supplying power to the mines at Big Oak Flat and about Groveland also, and operations are to be resumed at several of the mines. It is predicted that in a few months there will be greater activity in mining in that part of the county than at any time in the past. Among the mines that will be operated by electricity are the Longfellow, Mack, Mt. Jefferson, Del Monte, Cosmopolite and Nonpareil.—The mill at Sunnyside mine, southeast of Tuolumne, was started up today. W. P. Cunningham, superintendent, says sufficient ore is available for a steady run for several months.—A boring machine is being used at the Dondero placer mine, situated at Saw Mill Flat, near Columbia, to determine the depth of the gravel deposits and to prospect for new ones.—The shaft at the Santa Ysabel will be sunk 1,000 ft. deeper, which will make it 1,800 ft. deep. Nothing has been done at this mine during the past three months. E. C. Loftus, superintendent, recently made a trip to Massachusetts and induced the owners to advance sufficient money for carrying out the present plans; the work will be begun at once. For a long time, under a former management, good ore was taken from what is called the central shoot. From the grass-roots down to the 600-ft. level this shoot yielded well. At the 600 ft faulted and was not found again, although much work was subsequently done. Should the Santa Ysabel again become a profitable mine as the result of the work to be done, much good is expected to follow, as other mines on that part of the Mother Lode in which similar conditions are found will be opened to greater depths.—The Mohican mine, near Groveland, at which work was recently resumed, is employing five men.

Tuolumne, July 20.

YUBA COUNTY.

It is reported that the Blue Point gravel mine, near Smartsville, is to be re-opened, after years of idleness. It is

stated that before November water will be again running in the old Campbell ditch at Smartsville.

COLORADO.

CLEAR CREEK COUNTY.

W. E. Renshaw, manager of the Consolidated Gem Mines Co., has been sampling the medium and low-grade ore in the Gem vein, and has had tests made of the various classes of ore to determine how it could be handled at a profit; he says he has solved the problem. In all probability the Newton mill annex will be started with the addition of cyanide tanks. As it has been demonstrated that much of the value of the Gem ore is in the gangue rather than in the sulphide mineral, the silicious sand will be cyanided after concentration.—The interest of the late E. F. Lougee, in the Lougee & Dill lease, in the tenth level of the Lamartine mine, has been purchased from the administrator by John Rohner. The block of ground lies below the adit level and was recently equipped with an electric pump and hoist.—The Vidler tunnel is 10 by 12 ft. and is in over 1,300 ft. It is designed to reach West Argentine district and the Pacific slope of the continental divide. At the mill-site grading is nearly completed. Mr. Vidler says that driving on the Flossie vein will commence within 10 days.

CUSTER COUNTY.

At the Bassick mine the leases have been terminated and it is reported the pending deal will soon be consummated, and that a large force of men will soon be at work on the property.—An extension of the King of the Carbonates vein has been discovered in an adjoining property on the north by J. E. Ray, of Westcliff.

EAGLE COUNTY.

In Eagle canyon a large number of the fissure vein properties are being worked. These veins in granite every year show improvement as development proceeds. The ore is complex, it contains gold, silver, lead, copper and zinc. None of the properties has great depth. In every case where work has been carried on, the veins are continuous. Development is by adits.—The Maud S., under lease to the Minturn Mining Co., since starting six weeks ago, has a good showing of silver ore in the lower adit. On the hanging wall at the face a six-inch streak is coming in from the roof. Lead and iron also show in the bottom.—C. M. Anderson and Martin Stall, after several months of development in an adit, concluded to sink a winze on a chimney that came to the surface. Twenty years ago Anderson had a sulphide shoot in the vein, considered at the time low-grade ore, and he opened this. In 65 ft. of sinking the sulphide was found. In a drift run 32 ft. the sulphide has opened to a four-foot vein. Samples assay 3 oz. gold. Ore on the dump will be screened and several cars shipped.

GILPIN COUNTY.

Johns & Co., of Nevadaville, lessees, in the 250-ft. west level of the Kemp-Calhoun property in Leavenworth gulch, have received returns of 9 oz. gold, 27 oz. silver and 4% copper, on a shipment to the sampling works at Black Hawk. Chicago people are interested in the property, which is under the management of George MacGregor.—Articles of incorporation of the Gold & Bismuth Mining Co. have been filed with H. D. Williams, F. R. Van Meter, F. C. Jones, L. G. Schwallenberg and H. G. Hunter, of Denver, as the directors for the first year. The company will operate in northern Gilpin county, and will have its main office in Denver.

LAKE COUNTY.

The new mill in Lackawanna gulch, in Twin Lakes district, is nearly completed. It has been erected on the site formerly occupied by an arrastra.—Halleck & Funk have resumed operations on the Amazon lode.—F. H. Minard, of Denver, has been inspecting the claims of the Twin Lakes Gold Mining Co., and it is reported that work is to be resumed. An adit will be started that will cut the veins 1,000 ft. deeper. It was to determine the feasibility of this project that Mr. Minard visited the mine.

SAN JUAN COUNTY.

The ground is broken and all the machinery ordered for doubling the capacity of the Sunnyside mill at Eureka. The mill, which now contains 40 stamps, will be enlarged to

80, and will then treat 200 tons of ore per day. Other improvements are being made and the Sunnyside will soon have an up-to-date mill. The mill improvements will hardly be completed before the first of the year. The tram towers which were destroyed or dislodged by storms last winter are being replaced by Charles Dale, temporary towers taking the place of the permanent ones. For the past few months the mine has had very little interruption from steady work.

SUMMIT COUNTY.

The Orthodox mine, on Mineral hill, has been sold by the administrators for the estate of the late owner. This property has a production record of \$200,000 to a depth of 200 ft. The property was bought by the Wellington Mines Co., which owns the adjoining territory. — The Sallie Barber mine, on Bald mountain, one of the richest mines in the district, has been leased by the owners to E. E. Miller, of Breckenridge. — A party of Southern capitalists arrived in Frisco from Tennessee, Mississippi and Georgia this week, for the purpose of making an inspection of the property of the Mary Verna Mining Co. and the North American Mines Co. in Ten Mile canyon. They spent several days in looking after these holdings and also over other properties in the district. — The main adit of the Square Deal Mining & Development Co. at Frisco is progressing, and the indications are that it will cut one of the veins in a short distance. The country rock is highly mineralized with iron, and small seams of quartz with disseminated galena are coming in. The president of the company is now at the mine with a party of visitors from Illinois and Wisconsin. — The Monroe mines, adjoining the North American Mines Co.'s property in the Ten Mile canyon, have been leased and bonded to Conrad Hennick by the owners. This has been taken up by Denver men and is expected to be in operation shortly. This property has a splendid record of production in bygone years, when the ore from the main workings was shipped in carload lots and netted the owners \$19 per ton, mostly gold. Breckenridge, July 28.

IDAHO.

ADA COUNTY.

The Golden King in the Dixie district, which has lain idle for many years on account of litigation, is to resume operation. A great deal of work had been done and much ore blocked out before litigation stopped operations. The machinery is practically useless, having lain idle so long. The mine will be drained and put in working order and new machinery installed. — It has been settled that the Red Bird mine at Black Warrior will be taken by the Blue Cap Mining Co., represented by Ed Schwerd. L. W. Smith and J. Sebastian of Cleveland, officers of the company, have been inspecting the property. The company will take up the deal and work the property.

OWYHEE COUNTY.

The Portland group of mines, near Castle Creek, has been bonded to J. H. McGahn. These mines are situated 25 miles southeast of Silver City.

SHOSHONE COUNTY.

Official reports give the following concerning the value of the lead-silver ore in the Coeur d'Alene district and the cost of mining there in 1905. The Federal Mining & Smelting Co., which owns five mines in this district, extracted a total of 904,004 tons of galena, the value of which was \$6.60 per ton, and the cost of extraction was \$2.60 per ton. The Bunker Hill & Sullivan mine produced 342,414 tons of ore, the gross value of which was \$3.40 per ton, costing \$1.75 per ton to mine it. The Hercules Mining Co. produced 11,422 tons, valued at \$82.59 per ton, the cost of mining being \$11.41 per ton. — The Hecla Co. produced 97,366 tons, valued at \$9.25 per ton, the cost of which was \$4.10 per ton. — The Snowstorm, the only copper mine in the district, extracted 65,500 tons of ore at a cost of \$2.52 per ton, and the ore sold for \$12.74 per ton.

(Special Correspondence). — Markwell brothers announce that the galena vein has been found in the Sister mine near Wallace, 700 ft. from the adit on which the company has expended \$20,000. It is low-grade ore, but can be concentrated. — W. S. Trasker of Chicago, of the Bear Top Mining Co. north of Wallace, says the mill is running 16 to 18

hours daily and turning out 100 tons of concentrate per month, which assays 65% lead and 5 oz. silver per ton. The capacity of the mill is to be doubled. The raise from No. 1 tunnel to the surface will be completed in a few days. — Officers of the Idora Mining Co., of Spokane, announce a strike of five feet of milling and shipping ore in their property, samples running 50 to 65% lead and from 20 to 30 oz. silver. Some stoping has been done in No. 1 and 3 levels, the ore taken out being of high grade, and a large amount is ready for shipment. The Idora mine is in the Coeur d'Alene district. — The first shipment of ore from the Coeur d'Alene Consolidated mines, two miles east of Kellogg, will be made the last week in July. The property is near the Bunker Hill & Sullivan mine and consists of four claims. The main adit is now in 125 ft. and is headed for the junction of three lodes. — Shipments have been started from the Bluebird mine on the Blacktail mountains on Lake Pend d'Oreille, 42 miles northeast of Spokane, the ore being taken to the smelter at Standpoint. The ore is said to average \$85 per ton. — C. M. Crego of Spokane, vice president of the Interstate mine, located near the Hercules property at Wallace, states that the company will install a 500-ton concentrating plant and a large compressor. The company has 22 claims and has expended \$75,000 in development. The vein, which shows 75 ft. on the surface, has been broken into at 400 ft. depth in an adit.

Spokane, July 21.

MISSOURI.

CRAWFORD COUNTY.

Manville Jenks and J. H. Quinn have taken an option on the Baxter Lead & Zinc mine near Cuba for \$600,000. The mine is now paying \$9,000 per month.

NEVADA.

DOUGLAS COUNTY.

W. D. Kennedy, the discoverer of Buckskin, and one of the heaviest owners in the district, will resist the demands of the Western Federation of Miners, which has established a \$4 and \$4.50 scale in this camp. He says he will pay \$3.50 and \$4 per day, and no more. The Federation has appointed a committee to picket his mine and to send all non-union men from the district. Already several men have been sent out, their transportation being paid.

HUMBOLDT COUNTY.

In a new district, known as Seven Troughs, 25 miles west of Lovelocks, an important strike of gold has been reported, and men are said to be stampeding from every direction to this scene of Nevada's newest excitement. The find which created the initial excitement was that of a vein four inches wide from which ore was taken said to assay thousands of dollars per ton. The new field is in the low hills in Granite Springs valley.

The geology of the newly discovered mining region in the Pine Forest range, a short distance south of the Oregon line, is thus described by a miner in the new camp: "The formation is granite, lime and rhyolite, and the mineral zone can be traced for 10 miles. There are both wide and narrow veins, the richest ore occurring in seams in the latter. The grade of ore in the big veins is fair, but nothing can be said of the permanency of the ore deposits, for when I left the deepest hole was about 10 ft. There is no timber, and the water supply is limited, only what can be had in the draws. The country presents favorable conditions from a geological point of view. Some rich specimen ore is found, but the general run is from \$12 to \$20 in veins four to six feet wide, with seams in the orebody which carry ore ranging from \$50 to \$1,000 per ton. The camp may make a big producer, but it will take some time to really get even a fair idea of its possibilities."

LINCOLN COUNTY.

(Special Correspondence). — With the approach of the Barnwell & Searchlight railroad many mines are bettering their facilities, and preparing ore for shipment to the smelters. — The Duplex Extension, incorporated by the Pacific Coast Mines Bureau, of Los Angeles, is a new company, operating here. F. G. Tyrrell, its attorney, is here in connection with the title to the property, which was purchased from Allison & White, and consists of four claims, adjoining the townsite. Mr. Tyrrell states that his company will open

rate a mining exchange in Searchlight, under the name of the Broadway Mining Exchange.—A well-defined vein, four feet wide, with ore running \$50 per ton, has been cut in the north drift of the 300-ft. level of the Cyrus Noble. The mine has found more water in its lower levels, 15,000 gal. being now available daily for milling purposes.—Cobalt is reported in the bottom of the Searchlight-Crescent shaft.—Carter & Day have purchased the Searchlight-Diamond from Freeborn & Gehagan. It is stated that the interests of this property will be consolidated with those of the Searchlight-Western, which adjoins it.—George Weeks reports a new strike in the Newberry district, of a copper-stained quartz assaying high in gold. There are now more than 30 mines operating in Searchlight.—Gillingham & Price, of the United Investors Co., New York City, are in Searchlight with a view to acquiring mining properties for their company. Mr. Gillingham states that he has practically closed a deal for the purchase of a well-known mine and has the acquisition of another under consideration.

Searchlight, July 28.

NYE COUNTY.

The miners of Goldfield and Tonopah have voted by a large majority to demand an eight-hour day, which if not granted will be followed by a strike, which would tie up all southern Nevada mines, including Tonopah, Goldfield, Manhattan and Bullfrog districts. The miners in the White Horse district decided on a new scale to go into effect December 1, and there will be no trouble in that section. It is said the Tonopah Mining Co. has agreed to the eight-hour schedule; but other companies are holding for a nine-hour day. A peaceful settlement is expected.

(Special Correspondence).—Lee Garrett is reported to have struck it rich on the Sedan claim which adjoins the Copper Farm of the Manhattan Nevada Gold Mines Co. on the north. He discovered the vein which others had passed scores of times. A sample across 12 ft. assayed \$16 per ton gold. He purchased the property from the owners, and started to sink on this vein. At a depth of 15 ft. he struck 10 ft. of rich ore. Three assays at different points on this vein returned respectively \$340, \$570, and \$1,508 per ton gold. At a depth of 30 ft. he started a drift under it, when he struck another vein 2½ ft. wide, heavily mineralized with manganese and iron, many pieces showing free gold. The 10-ft. vein is of a whitish color and contains free gold, a sample from which taken across 2½ ft. returned \$200 per ton gold. Everyone owning property in the vicinity of the new strike is working hard to open up his ground. The Manhattan Belmont, to the southwest of the Sedan, has three feet of ore containing visible gold. The surface of the El Dorado claim of the Manhattan Nevada Gold Mines Co. pans gold, and work is to be started on this claim in search of the same vein. It is thought by some that this vein continues through the hill from the Sedan, across the Belmont and El Dorado claims, and into the Monday claim of the Original Manhattan Mines Co.—The strike on the Sedan, with the finding of rich ore by the Combination, Original Manhattan, and Paymaster Mining Co., has given a strong impetus to development in the western section of the Manhattan district. The management of the Manhattan Mammoth at East Manhattan has placed an order with the Fairbanks Morse Co. for a compressor plant for that property. This company has ore ready as soon as the mill is erected at East Manhattan.

The hoist on the April Fool claim of the Seyler Humphrey Gold Mining Co. is now in place, and will be in operation within a few days.—Free gold is being exhibited by A. H. Diehl, superintendent of the Manhattan Joker Mining Co. Dry washers are continuously at work on the Manhattan Cowboy Co.'s ground with good results.—A strike was made yesterday on the Manhattan White Caps, adjoining the Manhattan Mother Lode on the north, and close to the latter company's line where a four-foot vein was uncovered that assays \$60 per ton gold.

Manhattan, July 28.

UTAH.

BEAVER COUNTY.

The Majestic Copper Mining Co. has recently installed an

electrically driven pump having a capacity of 150 gal. per minute. At water level in the Majestic mine, a vein of lead-silver ore was found, and in cutting out for the pump high-grade copper ore was uncovered.

GRAND COUNTY.

There is more development work going on in La Sal district than ever before. Three properties are shipping ore, and the Basin stamp-mill is ready for operation. The camp of Basin is growing rapidly, new people coming in every day. The lateness of the season this year kept everything back until the first of July, and while there is still much snow on the north side of the mountains, work is going on. The Basin stamp-mill has been remodeled to treat the ores of this camp.

SOUTH DAKOTA.

CUSTER COUNTY.

(Special Correspondence).—Eastern stockholders of the Sagamore mine are here inspecting the property, of which L. P. Woodbury is manager. — E. C. Johnson, who sold the Gertie tin mine, has returned to Hill City from the East to resume active mining. — The Westinghouse Electric Manufacturing Co. has 90 people on the pay-roll.

Custer, July 24.

PENNINGTON COUNTY.

The Westinghouse Electric Mfg. Co., which recently bought the New York mica mine, near Custer, and established a factory there for preparing the product of the mine for use in the works at Pittsburg, is making arrangements to increase the capacity of the plant. The Westinghouse works require 400 lb. of mica splittings per day, but at present the output of the Custer branch is but 300 lb. per week, and W. J. Longmore has been making arrangements for a larger force to increase the output to the desired amount. New machinery for the factory has been ordered, and 175 additional boys and girls, 14 years of age and upward, will be given employment if they can be secured. At the mine everything is being arranged for continued operation upon a large scale, and the latest orders received have been for the construction of a boarding-house for the men, residence for the foreman, machinery and equipment.

CANADA.

BRITISH COLUMBIA.

Following is the tonnage of ore shipped from, and crushed at, the mines of Rossland for the week ending July 28: Centre Star, 2,430; Le Roi, 3,120; Le Roi Two, 630; Total, 6,180; Total for year, 183,779. — Ore shipments from Boundary mine for week ending July 28 were as follows: Granby mines, Phoenix, 15,829 tons; British Columbia Copper Co., Deadwood, 450; Dominion Copper Co., Brooklyn-Stemwinder, Phoenix, 2,904; Rawhide, 396; Sunset, 904; Mountain Rose, 70; Emma, Summit, 330; Providence, Providence, 140; Skylark, 60; Total, 21,083 tons. Total for 1906 to date, 703,720 tons. Smelters treated ore as follows: Granby Co., 16,602 tons; Dominion Copper Co., 4,274. Total for year to date, 708,352 tons.

ONTARIO.

(Special Correspondence).—The country north of the Cobalt silver district, between Lake Temiskaming and Lake Abitibi, is full of prospectors searching for any kind of mineral that may exist. Mr. Wilson, of the Canadian Geological Survey, is making a preliminary survey of the region north of the National Transcontinental railway.—It is reported gold has been found in the black sand of the Croche river, which flows southerly into the Saint Maurice, at La Tukue. An old Colorado miner, named Hayes, panned the sand and found gold. Samples assayed about \$1 per ton. A New York company has taken up 500 sq. m. for the purpose of prospecting, and sent an engineer into the district who reported that there was little or nothing found. Hayes since reports that he has discovered the principal gold-bearing lode of the region. The New York company has an agent on the property and an assayer is kept busy testing samples brought in from this land.

Cobalt, July 28.

Personal.

HENNEN JENNINGS is at Berkeley.

A. H. ACKERMANN is in Rhodesia.

O. B. PERRY is at Dawson, Alaska.

S. F. PARRISH is now living at Los Angeles.

R. C. CANBY is taking a holiday in Connecticut.

C. REGINALD ENOCK is visiting England from Peru.

H. C. HOOVER left London for New York on August 3.

GEORGE W. MAYNARD is examining mines in Georgia.

H. H. CLAUDET has returned to Rossland from London.

E. F. DE LANO is at Los Angeles from Fenner, California.

C. R. CORNING sailed from New York for Europe on July 25.

H. KILBURN SCOTT has returned to London from South Africa.

ARTHUR L. WALKER has returned from a flying trip to Cananea.

JAS. W. NEILL is at Merced, Cal., inspecting dredging ground.

E. ALEXANDER is in San Francisco, on his return from Manchuria.

F. H. MINARD has been examining mines near Twin Lakes, Colorado.

ROWLAND F. HILL, of New York, is examining mines at Pulaski, Virginia.

W. H. WEED is examining the Nickel Plate mine, in British Columbia.

HUDSON H. NICHOLSON is visiting Goldfield and the new mining camp of southern Nevada.

C. J. ADIMI has been appointed general manager for the Cable Consolidated Co., in Montana.

JOHN ROSS, JR., has gone from Sutter Creek, Cal., to Grants Pass, Or., on mining business.

LEONARD S. AUSTIN, professor of metallurgy in the Michigan College of Mines, is in Colorado.

DANIEL GUGGENHEIM left Vancouver on July 31, to inspect his company's holdings in Alaska.

H. L. SLOSSON has returned to San Francisco from New York and has left for Virginia City, Nevada.

H. G. SCHRADER, recently superintendent of the Johnnie Con. Gold Mining Co., is now at Los Angeles.

S. S. FOWLER has been appointed manager for the Canadian Metal Co., Ltd., at Frank, in Alberta, Canada.

W. E. RENSHAW, manager of the Gem Consolidated mines at Idaho Springs, Colo., has gone to Pittsburg.

E. C. LOFTUS, superintendent of the Santa Ysabel mines, near Stent, Cal., has returned to the mine from Boston.

W. J. ALSTEAD has returned to Seattle from Chettana, Alaska, where he has been inspecting copper properties.

A. M. ROCKWELL has become superintendent of the Bonanza King mine in San Bernardino county, California.

R. L. LLOYD, chief of the reduction department (mills and smelters) of the Greene Consolidated Copper Co., has resigned.

C. J. PRICE, on a visit home from Johannesburg, delivered an address before the Black Hills Mining Men's Association on July 19.

FRED HUTCHINSON and P. BELL, of North Queensland, Australia, are in San Francisco. They leave for Australia on August 16.

A. M. ROCKWELL is superintendent of the Bonanza King mine, in the Providence mountains, near Fenner, Cal., for the Trojan Mining Co., lessees.

T. A. VARDEN, in charge of the Uncle Sam and other mines, is now living at North San Juan, in Nevada county, California.

GEORGE A. GUESS, chief chemist of the Greene Consolidated Copper Co., has been appointed chief of the reduction department.

FRANK J. BOOTH, superintendent of the Mexican Gold Copper Co., has returned to the mines at Colonia Juarez, Mex., from Berkeley.

CHARLES BUTTERS has been awarded, by the Institution of Mining & Metallurgy, London, the gold medal in recognition of his researches in the extraction and treatment of gold ores.

JAMES CRONIN, of Spokane, who discovered the St. Eugene mine at Moyie, B. C., has resigned as manager of that property and of the Centre Star mine at Rossland, B. C., and will make a tour of Europe.

GEORGE S. WATERLOW, of London, vice president of the Snowshoe Gold & Copper Mining Co., is in British Columbia for the purpose of completing negotiations for selling the property to the Canadian Pacific railway.

E. C. GARDANIER, of Salt Lake City, has gone to Phoenix, B. C., where he is superintendent of the Dominion Copper Co. mines, relieving THOMAS R. DRUMMOND of part of the work. Mr. Gardanier was formerly with the Highland Boy mine at Bingham, Utah.

In steam pumps there are two completely antagonistic elements to be reconciled, namely, the steam, an elastic expanding vapor at one end, and the water, an inelastic, non-compressible fluid at the other. In moving the water, an effect must be obtained as near absolute uniformity as possible, while, to secure the greatest economy of steam, it is necessary to produce the widest practicable variation of pressure upon the steam-piston. It is obvious that some means must be provided within the engine to equalize these widely different demands, either by the use of heavy fly-wheels, or by compensating cylinders, as in Worthington high-duty pumps.

It is a common belief among miners that the grain of galena is influenced by its richness in silver, the general idea being that a coarse-grained galena is likely to be poor in silver, and a fine-grained variety, rich. While no general rule can be laid down, nevertheless, as regards certain districts, some connection is observable between the grain of galena and its silver contents. Thus, at Broken Hill, Australia, the coarse-grained galena is said to be generally richer in silver than the fine-grained. In Mexico, the contrary rule prevails as regards the ores of a particular mine, namely, that the fine-grained galena is the highest in silver.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

GRAPHITE, unless of good quality, free from earthy or other impurities, is not in demand on the Pacific coast. A very large amount of artificial graphite is now produced for those purposes not requiring the best amorphous or crystallized mineral, and the cheapness of the manufactured article bars out the poorer natural product.

THE minimum interval of rest which should be allowed a stamp, on striking the die, is one-tenth of a second. If the speed of dropping is such as to give a less interval, then breakages will occur, beginning with the arm of the cam.

WOLFRAMITE, HUBNERITE AND SCHEELITE are the three minerals from which tungsten is derived for the making of a special steel. Tungsten was formerly used chiefly for making colored cotton goods 'fast' or washable. Its metallurgical properties have given it a greatly increased commercial value.

CALIFORNIA TURQUOISE.—The turquoise mines of New Mexico and Arizona have lately not been as productive as formerly. The turquoise properties of California and Nevada have, however, been increasing their output. Considerable quantities of turquoise have been taken from the mines in the desert region of San Bernardino county, Cal. Many of the stones range from 50 to several hundred carats in size. Some of them have sold as high as \$1,500 each. The color is pale, but it has gained favor.

IN CALIFORNIA the float from veins and mineralized zones, as far as known to us, lies on the lower side of the outcrop, and its position in every instance may be assigned to the forces of gravitation. Possibly there may be a few local exceptions in the Sierra, where float has been carried up hill by ice. The fact of float, and gold also, being scattered on hillsides below outcropping veins is a fact made practical use of by experienced pocket hunters and intelligent prospectors generally.

IT IS TRUE that fabulously rich placers have been found at intervals from the Arctic ocean southeastward through Alaska and British Columbia and again through the State of California as far south as Calaveras county, but rich placers have also been found in Tuolumne and Mariposa counties, in Kern county and in Arizona. The absence of extensive rich placer diggings in Washington and Oregon, and in portions of California, is due to either the absence of rich veins in the bedrock, or the placers are concealed beneath vast accumulations of lava and have never been discovered. In southern California large gravel deposits, undoubtedly occupying the beds of ancient rivers, are found in the San Gabriel and San Bernardino mountains at elevations ranging from 7,000 to 10,000 ft. above sea level, and the gravel has been worked for the gold it contains but is only rich where concentrated in narrow gulches crossing the older deposits. Near Newhall, in Los Angeles county, there are several square miles of gold-bearing gravel. In San Diego county there is a peculiar ridge near Ballena. It resembles the back of a huge whale, whence its name, *ballena* being whale in Spanish. This ridge is wholly composed of auriferous gravel, consisting of material all foreign to the locality, nor is it known where it had its origin. It is merely a remnant of an ancient river, the greater portion of which was long since removed, by the ordinary process of erosion, or possibly, in part, by ice.

URANIUM is now increasingly used in photography. The nitrate of uranium serves, in conjunction with sulphocyanide of ammonium and ferrieyanide of potassium, the purpose of intensifying an undeveloped plate. The same salt is also used to get the red glow effects in lantern slides.

GLACIATION IN CALIFORNIA: How far south the great ice sheet of early Quaternary time extended it is impossible to say, as the vast erosion to which the greater portion of the State has been subjected removed all traces of glaciation, including moraines, except from the high Sierra. Le Conte says, in 'Elements of Geology': "During the fulness of glacial times a continental ice-sheet covered the whole of British Columbia, Northwest Territory, and Alaska, connecting in high altitudes with the eastern sheet. * * * * The ice moved southward, southwestward, westward, and even northwestward. Southward it certainly reached as far as latitude 48 degrees, westward it flowed over the Coast range, filled the valleys (now submerged) separating the great coast islands from the mainland, flowed over these islands, and ran into the sea beyond. At the same time it is certain that the Sierra was completely mantled by snow; and great glaciers, some of them 40 to 50 miles long, filled all the profound canyons which trench its flanks. At the same time, also, there is some evidence that even the Coast range, favored by proximity of the sea, had their perpetual snow-cap from which issued glaciers filling the principal valleys." He adds, in a foot-note: "Undoubted marks of ancient glaciers are found about Berkeley, 300 ft. above the bay." This undoubtedly refers to striated rocks found in the open fields north of the city of Berkeley. Some geologists dispute this evidence, assigning the stria to other causes. Some of them are undoubtedly due to rock movement (slickensides), others appear difficult of explanation by any than the glacial theory.

A REVERBERATORY FURNACE may be built of *adobe* and stone. *Adobe* or sun-dried brick used for this purpose should be made of suitable earth—that is, must contain sufficient clay. Straw should be used in amount just sufficient to hold the brick together. They should be 9 in. wide, 18 in. long and 4 in. thick, this being a convenient size. The binding mortar should be of the same material as the *adobe*. The walls should be three feet thick. The foundation may be made of stone and the buck-stays may be made of 10 by 10-in. timbers, held by iron rods. The *adobe* for the arch should be built to fit, and if material is not available for making a form to sustain the arch while in construction, fill the furnace chamber with loam or sand, crowning the top to the desired shape, then place the *adobe* in position, using as little clay or mortar as possible. When in position they should be carefully hammered into place with a block of wood. When finished the sand may be removed from the chamber and after the placing of the stays the furnace is completed.

THE OCCURRENCE of galena, associated with other sulphides in quartz, may be indicative of the presence of silver, but in some districts it is distinctly an indication of an increase in gold. Native gold is occasionally seen in crystals of galena, though not commonly. Likewise, the appearance of zinc-blende may indicate an increase in either gold or silver in an ore, as in California. In some districts zinc-blende is a sure sign of impoverishment.

PRACTICAL LIFE is a Rule of Three sum, in which your duty multiplied into your capacity and divided by your circumstances gives you the fourth term in the proposition, which is your deserts, with great accuracy.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Pans vs. Tubes.

The Editor:

Sir—It has occurred to me, in the case of many of the controversies over the respective merits of grinding pans and tube-mills, that no real basis for argument would be left if more attention were paid to defining the work to be performed by each machine. For instance, is total sliming of the ore the principal consideration, or is sliming only to be the final stage in the crushing process?

In the Transvaal, total sliming—or at least total fine grinding—of the stamp-mill product seems to be the desired end, while in Kalgoorlie stamp-mill practice total sliming is wanted only after a preliminary concentration has been effected. Both grinding pans and tube-mills are in use here, and each fills satisfactorily its own position in the scheme of treatment. The introduction of the grinding pan into the milling practice of Western Australia was undoubtedly due, in the first place, to a desire to lower the treatment costs in wet-crushing mills, which were using the bromo-cyanide process on sulpho-telluride ores. Its success in this particular function has led to its development as a grinding machine pure and simple on many different classes of ores. The conditions which introduced the pan were:

1. A high consumption of a high-priced chemical, namely, bromo-cyanide.
2. The knowledge that in this respect expenditure could be most easily reduced by eliminating by concentration as much of the gold as possible before treatment with bromo-cyanide.
3. An ore, the valuable portion of which was most susceptible to sliming.
4. The necessity of reducing the crushed ore from the stamps to a size which would free the mineral particles for concentration, with the creation of a minimum percentage of slime.

These conditions seem somewhat contradictory, inasmuch as good concentration practice demands that the mineral be saved in as coarse a condition as possible, while on the other hand a high extraction from the roasted concentrate demands that all mineral particles be crushed sufficiently fine to free them from enclosure in gangue material. It is, however, this very conflict of demands which has made a place for the grinding pan, the construction and operation of which renders it possible to regulate with some accuracy the size of the product which it discharges.

While stage grinding, as a preliminary to concentration, is the work for which the pan was originally introduced, its field of usefulness is by no means confined to this particular duty. Its efficiency as a fine grinder is being steadily demonstrated, and the limit to which fine grinding in pans can be carried is not yet in sight.

In regard to sliming of the total stamp-mill product, it seems by no means settled whether stage grinding in pans with final sliming in tube-mills, will not prove more economical than direct sliming of the whole product in tube-mills. There is no doubt, however, that as an adjunct to a stamp-mill for the purpose of giving increased efficiency to the stamps by allowing the use of coarser screens, the field for both these machines, used in combination with each other, is a wide one.

It is the successful development of the grinding pan which has enabled the wet-crushing mills at Kalgoorlie to survive the increasing competition of the dry-crushing and roasting mills; and it has been the chief factor in

increasing output and decreasing costs of the stamp-mills at the quartz mines outside of Kalgoorlie.

D. P. MITCHELL.

Kalgoorlie, June 9, 1906.

A Mining Method Wanted.

The Editor:

Sir—New Superintendent has brought out some valuable ideas in connection with his query for a mining method. To discuss the subject further, a few additional points of information are necessary. For instance, his description of the orebody is vague. Does it stand well, or is it broken up or brecciated, and does it 'cement' on exposure to air, as do many of the desert deposits? This point, combined with the value of the ore and the profit per ton, will determine whether it is good mining to extract the whole orebody, or whether pillars should be left to support the roof or hanging wall. To mine waste from raises and drifts, for filling, may more than counter-balance the profit to be derived from robbing pillars. The site of the mill, whether above or below the adit, will, I think, determine the expediency of a shaft in the foot-wall. I think the expense of artificial ventilation would more than offset the difference of cost for a shaft, or a raise, in the foot-wall—should this be necessary—particularly as all the schemes submitted thus far start to stoep from the adit-level upward.

From the data furnished, Mr. Nickerson's solution appears to me to be the most practicable, except that to supply enough filling, the top of the raise A F should be continued on a 50 deg. incline to a 'glory hole' on the surface, where waste could be mined at a minimum cost and drawn out where desired.

ALGERNON DEL MAR.

Enterprise, Cal., July 26, 1906.

Mining Quacks.

The Editor:

Sir—We are all familiar with the medical quack and we know that, in most places, he is outside the pale of the law, and although most of us are acquainted with the genus mining quack, the latter not only exists, but does very well out of a gullible public. The legitimate members of the profession are perhaps powerless to restrict the fraudulent mining engineer, but when all's said and done, why should it not be illegal for a man to call himself a mining engineer unless he has earned that degree by a course of study? There are many men who have not had the advantage of a college training, who through sheer ability have risen to eminent positions, and while the restriction mentioned might unjustly affect a number of worthy men, without doubt it must eventually tend toward greater protection to the investing public, beside giving to the title a greater significance than it now possesses. The only hardship it can work is to cause a comparatively few men either to pass certain examinations or drop a handle they are not entitled to.

It seems to me that legitimate mining engineers do not take any pride in the appellation, with the result that the mining quack is much in evidence in every mining community. The individual of this type—usually an ex-day's pay man—loves to use a multiplicity of high-sounding technical terms, especially those relating to geology, and he further has a great partiality for that particular form of ore deposit known as the fissure vein. Further, he is very partial to a double-barreled degree such as 'Mining Engineer and Geologist,' or 'Mining Engineer and Metallurgist.'

In my time, I have seen some gems in the way of literary composition, but I think the one herewith is quite a curiosity, and in its way, worthy of Mark Twain. I

am sure every mining man will appreciate the humor of it. Does it not seem a pity that a man who is paid a fee for writing such a report cannot be put in jail for fraud?

[The report is bad, but not worse than many we have seen; so we quote only two paragraphs.—Editor.]

"The slate on the hanging-wall side of the lode area is metamorphic on altered slate, hard silicious carrying quartz veins, and highly mineralized. The strata on the foot-wall is chiefly metamorphic slate, with in places an intrusion of felsitic rock, and plumbiferous slate with calcite disseminated through the slates. The whole stratification is crushed and fragmentary, and probably will not be settled until a depth of 500 feet.

"Is nearly north and south—a true fissure lode trending through a belt of mineralized rock, which by its appearance and constituents should extend for miles. The lode trending through the belt, incased by different stratas, renders it a contact vein, so that in the double capacity of a true fissure and contact lode, there is an assurance of permanency and value in depth, and I also premise that the size of the lode would be larger and more regular in depth."

This type of individual, as a class, is a menace to the public. He may, through being successful in some particular instance, have acquired a following, but what does he, as a usual thing, know of mining engineering? If he were prohibited the use of the title 'Mining Engineer,' he might adopt that of 'Mining Expert,' and we could then have him safely labeled and more or less out of harm's way.

There is another variety of mining quack who plays the comparatively safe game of reporting unfavorably on ninety-nine mines out of one hundred he visits. This class of individual is shrewder than the optimist typified by the charlatan just quoted, but the mainspring of his pessimism is controlled by fearfulness of results, owing to a lack of knowledge of the problems involved, and as his instinct of self-preservation is very strong he rejects a proposition sooner than shoulder the responsibility of recommending it. He knows that a mine once turned down always has more or less of a stigma attached to it, and he feels that this is apt to exercise some influence with the next man that comes.

Australia is the home of the mining quack; they grow on bushes there. Mining schools are in their infancy, and as mining is an active industry, very naturally a demand exists for reports for intending investors. There being practically no school-of-mines men, the quack has had to fill the gap. These men have sprung from all ranks of life; some of them have worked in mines, some are ex-sailors, and then there is the newspaper reporter.

One of the most flagrant cases of company mismanagement and unfulfilled promises known to the London mining world is that of the Etruscan Copper Estates. This company spent about half a million pounds sterling on a wild cat on the advice of a quack who learned his mining while writing for the mining columns of a daily paper. These ex-newspaper men are a particularly pernicious set. On account of their writings they get well known, and writing with a facile pen they fill their articles with glittering generalities and safe prophecies, which they get out of other men's mouths, and only the man who has an intimate knowledge of the mine or district they are describing, can detect their fallacies. It is marvellous how few people, even among those who have sufficient knowledge, stop to analyze what they read. Or, on the other hand, figures and information are given, and it is taken for granted they are correct. No matter what a man knows, to be useful as a mine examiner, he must be able to write a readable report, and that is where the newspaper variety of mining quack has the advantage over his less fortunate, though perhaps more capable fel-

low quacks who have no 'larnin.' I think we should recognize these men in some manner, and label them for identification, say, by giving them the degree M. Q.

VIATOR.

London, July 13, 1906.

Salton Sea and the Climate of Nevada.

The Editor:

Sir—It would be well for the desert country north from the Salton Sea if that inland lake were allowed to remain, and the inflow from the Colorado river allowed to continue.

During the present month it has rained every day in the vicinity of Lida, Esmeralda county. At Goldfield there have been showers almost daily, and rain-clouds are in sight at all times now, and have been for a month past. The result is that Goldfield is almost a summer resort. The temperature seldom gets above 90 deg. in the shade, and the nights are cool and pleasant. Last year, at this time, we occasionally saw clouds, but we had no rain. It appears that the prevailing southwest winds bring the clouds, laden with moisture from the evaporation from the Salton Sea, and these clouds give the rainfall, which if continued, will in time change these dry hills and plains to a fertile country with a different climate to what it has had in the past generation.

The sunsets in Goldfield, with the cloud effects, would delight any artist, and it is doubtful if they can be excelled anywhere for brilliancy and coloring.

ALBION S. HOWE.

Goldfield, Nevada, July 19, 1906.

USE OF FIRE-CLAY.—An experienced furnace builder and fire-brick manufacturer has the following to say of fire-clays:

Fire-clays are as numerous as their uses are varied, and prices differ according to quality. In exceptional cases only is much consideration given to the efficiency of the material; the main question being, apparently, cost per ton without regard to its refractory qualities. We find this verified every day in works where the very best fire-brick are used, yet they are laid with mortar made from the poorest and cheapest fire-clay on the market; the result is the burning out of the mortar in a little while and opening of joints, allowing the flame to cut away the bricks, which would last very much longer if laid with good fire-clay. When a furnace is to be repaired, the items of labor and material necessary for repairs are very small in comparison with loss of production resulting from the closing down of the furnace, and for this reason, if for no other, it is poor economy to use cheap mortar-clay with which to lay high-grade fire-brick or silica-brick. If a purchasing agent, mill manager and furnace builder were offered a brick made from a common clay, with the assurance that it would give as good service as one made from what is known as the Pennsylvania flint-clay, the person making the claim would be simply laughed at; at the same time they are buying these common clays with which to lay their No. 1 brick, and it is difficult to convince them of their error.—*The Industrial World.*

A METHOD of amalgamating in rotary mills of the Bryan type is recommended by an authority as follows: First, use enough quicksilver to keep the amalgam liquid, thus allowing it to accumulate in the annular space between the dies and the rims of the basin; secondly, to replace the old dies, when a little more than half worn out, with new ones; and, thirdly, to clean up the mill at least every two weeks—or oftener, if rich ore is being treated.

Experiences in Stamp-Mills.

Written for the MINING AND SCIENTIFIC PRESS
By ALGERNON DEL MAR.

Most articles on milling deal with mills that are treating ore under the particular conditions that have proved by experience to be the best for that particular ore, and

the mill would soon have been paid by increased extraction and time saved, for the main expenses were going on when the mill was idle and the cost per ton increased accordingly, putting out of consideration orebodies that could otherwise have been worked at a profit. Some mornings the plates and even the battery had to be thawed out with hot water and during the day the heat was sufficient to cause quite a variation in the consistency of the amalgam. Singularly, this extreme change of temperature did not appear to harm the silver plating, principally, no doubt, because a thick, firm coating of amalgam was allowed to remain on the plates. This coating protected the plating and allowed some variation of consistency due to change of temperature.

Another Nevada corporation erected a mill that was run by steam, the boiler being of the locomotive type with no masonry. The assayer returned an analysis showing the water to contain about 20% of solid matter, principally common salt. The mill, consisting of only five stamps, the millman had to fire the boiler. To facilitate the removal of salt from the boiler, a top and bottom blow-off was

we seldom hear of the experiences of those milling operations that have turned out failures, either through lack of funds or through ignorance of first principles.

The mill being the heart of a mine, it should be treated as such; it should be of the best workmanship throughout and should never be allowed to deteriorate, for once wear starts, either from a loose nut or a bent rod, the efficiency of the battery soon suffers.

A certain Nevada corporation installed a five-stamp mill and concentrator, but they failed first to obtain a constant supply of water and, secondly, they were in such haste to get rich that they failed to cover the building. It is needless to say that the mill never produced enough to pay for a housing, not through lack of gold in the ore, but through lack of conditions favorable to efficient work. The water was only sufficient for a 12-hr. run and had to be pumped back, in a more or less slimy condition most unfavorable for amalgamating fine gold, and the result of the mill being uncovered was that in cold weather all pipes had to be blown out with steam every night and it required at least two hours every morning to start the machinery. The small expense of covering

provided. The theory is that the salt will rise to the surface instead of, as one would suppose, sinking to the bottom. At all events the boiler was blown off every

A Stamp-mill Out-doors.

Mortar Sunk in Cement.

half hour. This excessive amount of saline matter did not cause foaming, but it formed a deposit in the injectors, soon putting them out of commission, and the least possible leak around the rivets of the boiler became so enlarged that huge coatings of rock-salt formed wherever such leaks took place. Salt was even carried with the steam into the cylinder of the engine. It became so difficult to keep up steam that the millman had to be stoker. By emptying the boiler every other day and filling with good water an improvement was noticed.

A trial was made with the lignite coal that outcrops about 18 miles from Tonopah. This cost \$18 per ton delivered at the mill, while wood cost \$7 per cord. This coal proved a failure, for steam could not be kept up at all. The coal would burn with a fierce heat when first put in the fire-box, but it would soon cake to a sticky mass that would prevent the air from entering. A forced draft did not improve matters. In half an hour the fire-box was a mass of clinker. With a moving grate mechanically fed it might answer, but this coal could not compete with pinon wood at any reasonable ratio of cost.

The old millmen in Plumas county were fond of having as many stamps as possible on a cam-shaft, as witnessed by the monuments all over the county. It was common to have twenty on a shaft. Considering the tendency toward the opposite extreme at the present date, an experience with one of these old mills is quite an adventure, especially in the year 1905 or 1906. The particular mill referred to had 15 tappets on the cam-shaft, with no mechanical means of setting a tappet readily except by hanging up all the stamps but the one to be set, and revolving the cam-shaft until the tappet had reached its position on the stem. That a tappet could be set while all the other stamps were dropping was something quite unheard of and was not considered practicable, so an overhead crawl was not installed, but at least an hour a day was lost for the whole 15 stamps.

The system of amalgamation was to allow the silvered plates to harden, scrape with a chisel at the end of the month and then wait two weeks for the plates to get in fair condition again. When new silvered plates were put in and it was recommended to amalgamate in the usual way, it was pointed out that so and so had made a successful extraction with raw copper plates. Now everyone who has had experience with copper plates will have noticed the difference physically between a raw copper plate and electro-silvered plates that have had the silver worn off. Whether this difference is due to a physical change caused by galvanic action, the effect is to make a worn-off silvered plate a poor amalgamator while the soft raw copper with proper care gives good service. This explains why it is so difficult to keep a worn silvered plate in good condition and shows the importance of a careful study of the amalgamating conditions so as always to keep the silvered plates from showing copper. Some ores contain chemicals sufficiently strong to attack silver even if protected by amalgam; in such case raw copper plates may be of benefit, but otherwise the electro-plated coppers are more efficient.

The importance of keeping a mill in thorough repair was well exemplified in the case of a mill in southern California. This mill was allowed to run down so badly that no millman would take hold of it without a premium. But for the haste of the management to obtain a big tonnage and consequent low cost, the mill, with a small outlay, could have been kept in good condition and in the end the cost per ton would have been less. Carelessness in keeping the guides in order led to most of the trouble. The fact that the mortars had no housing or covering on top was due to the same cause, for the guides being worn so that the stems had an inch or more play, the stamps had so much lateral movement that a covering over the mortar was almost an impossibility. The tappets and shoes hit, causing them to loosen, so that to keep the 20 odd stamps going required the millman to be on the jump every minute of his 12-hr. shift. There being no protection from tappet-keys dropping into the mortar, broken stems were of frequent occurrence. The claim put forward was that the iron guides were of no use and wore out in a short time, but the fault was in allowing them too much play to start with and in not keeping them in place afterward. The concrete mortar-blocks

proved a failure in this mill, no doubt because the nuts of the mortar-bolts were allowed to loosen and, once the least movement took place, the deterioration was rapid and complete.

An experiment with rolls may be of interest. An ore containing 20% of partially oxidized copper pyrite was run through the rolls with a stream of water, screened and concentrated. This process proved a failure by reason of the action of the copper salts and free acid on the screens, and all iron or steel with which it came in contact. That the rolls and screens could have been operated dry, and the crushed material mixed with water before concentrating, had not been considered.

That a stamp-battery was more favorable to the amalgamation of the gold was evidenced where a dry-roller mill was replaced by a stamp-mill. The ore, after being crushed by the rolls, was mixed with water and run over silvered copper plates, giving an extraction of a little over 50%, while the same ore treated in the stamp-mill yielded over 80 per cent.

CEMENT AND CLAY.—The quantity of portland cement used in California is far in excess of that manufactured in the State. With large deposits of limestone and clay quite widely scattered through the State and a large fuel supply, it would seem that the cement industry ought to increase rapidly. The State should be exporting rather than importing cement. For many years the development of the cement industry, like many other manufacturing industries in California, was hindered by the high price of fuel. With the opening of great oil-fields this difficulty has been overcome. Three cement factories are reported to be in operation, situated, respectively, at Napa Junction, Colton, and at Cement, near Suisun. The oldest factory is at Colton. The one at Suisun began operations in 1902 and the one at Napa Junction in 1903. The clays and the clay industries of this State are also important at this time. Large works are operating in Alameda, San Joaquin, Amador, Calaveras, Contra Costa, Kern, Los Angeles and other counties. Immense deposits of clay were discovered by the San Francisco and San Joaquin Coal Co. in the opening up of coal deposits at Tesla. The mines will supply a fine grade of pottery and fire clays. In the area about Carbondale, Amador county, and between Carbondale and Ione, there are extensive deposits of high-grade clays. Clay is found in a massive bed, 18 to 20 ft. thick, on the Ione-Sacramento road. There are many clay deposits of varied character in Butte county. Fire clay was discovered in Calaveras county in beds that overlie croppings of copper ore. Stewartsville, Contra Costa county, is the source of supply for large works at Antioch. On the south side of the Antelope valley, at the end of one of many felsite porphyry buttes, clay is taken out. Clay suitable for the manufacture of pottery occurs in large beds on the south bank of the Merced river. Kaolin has been uncovered in three places in Placer county. Fire-clay has been found in the foothills of the southwest slope of the Santa Ana mountains, Orange county. A belt of clays of superior quality extends in a general direction west of north from Elsinore to Corona, in Riverside county.

CONCENTRATE should be dried as thoroughly as convenient before shipment to reduction works. There will be some loss from the sacks by dusting and the dust may be the highest grade stuff; but even 10% moisture means 200 lb. per ton, on which to pay transportation charges and smelter discounts. Where freight is no more than \$5 per ton—it is often much more—the cost of shipping this 10% water is 50c. per ton of ore. The loss by dusting, if canvas sacks are used, will probably be less than 0.5 lb. per sack, or say eight pounds per ton. On \$100 concentrate this means a loss of 40c. per ton.

The Big Furnaces of the Anaconda Smelter.

By LEONARD S. AUSTIN.

*Apart from the general organization of the Anaconda Copper Mining Co., the Washoe plant and its accessories at Anaconda, Montana, are under charge of the local manager, Mr. E. P. Mathewson. This is the largest non-ferrous metallurgical plant in the world, and illustrates, under the given conditions, the natural development resulting from the necessity of a complex organization.

With many smaller metallurgical plants the organization has generally been arranged so that the business manager gives his whole attention to business details,

Again, in increasing the length of the blast-furnaces at one time from 15 to 51 ft., it was necessary to know whether it were possible to remove a jacket while the blast was on, and to cut out or to repair one part of the furnace while the rest was in operation. At the time the change was made copper was selling at a profitable figure, and it would not do to shut down in order to make changes. It was therefore necessary to make the change with practically no delay in running. With such considerations, on the financial side, the manager knew he must advance only along lines involving no delay; had he to do with the technical side only, he would have put up

A Copper Blast-Furnace, 56 Inches by 51 Feet.

while the superintendent attends to the technical matters. With the Anaconda Copper Mining Co., however, a technical man was chosen to attend to business details also; the wisdom of this arrangement has often shown itself, since, in this particular case, the mastery of business detail has been as satisfactory as when performed by one who had always confined his attention to business only. Moreover, a comprehensive view of the whole process by a master of technical detail has proved equally gratifying. For example, the 50-ft. reverberatory furnaces of three years ago were successively increased in length to 65, 85 and 102 ft., since it was not known what length of furnace could be used. To make these changes required the expenditure of \$120,000 (all of which was recovered out of the economies attained during the course of the experimenting), and success required a complete knowledge of the technical side of the problem, as well as a clear idea of what the finances of the company would permit.

with the apparent necessity of shutting down so as to make the improvement.

In order that the manager could give the closest attention to technical questions, an assistant superintendent was appointed to advise with him and with the heads of departments, and to take his place during his necessary absences.

The different departments about the works are under charge of foremen or superintendents, who are specialists in their line of work, and who work in harmony with one another. There are superintendents for the concentrating mill, sampling departments, power-houses, blast-furnaces, converters and the arsenic plant; also chief foremen for the reverberatories, the roasters, the briquetting-plant and the slime-ponds. In addition, there is a general foreman of the works, who has full charge and authority in the absence of the superintendents of the departments. The 8-hr. system, in use at Anaconda, requires that there shall be three shifts daily, so that the general foreman is relieved by two foremen who assume his duties on the

Abstract from author's proofs of a paper entitled "The Washoe Plant of the Anaconda Copper Mining Co. in 1905," *Transactions of the American Institute of Mining Engineers*, July, 1906.

*Ore-Bins.*

other shifts and who relieve each other on the afternoon and night-shifts every two weeks, while the general foreman always keeps the morning or day-shift. The departments having superintendents, also have foremen, a head foreman, holding the morning shift, and two reliefs alternating on the other two shifts. The chief, or morning foreman, has the larger measure of authority and responsibility. Thus, at no time, is any department left uncontrolled, since the foremen relieve one another, and, as an additional precaution, the general foreman attends not only to the general supervision of the plant but also to those matters belonging to no particular department. Repairs and general construction are under supervision of the mechanical superintendent with an assistant and a head mason. The complex handling of materials is in charge of a master of transportation. For experimental and control work there is an engineer of tests. A chief chemist reports all assays and determinations. The accounting is supervised by a chief clerk, and the purchasing of supplies,

both for mine and works, is in charge of a purchasing agent.

The blast-furnace building formerly contained seven furnaces, each 56 by 180-in. area at the tuyeres. These were arranged with their longer axes parallel to the length of the building, for convenience of charging, by means of track charge-cars. A new furnace was made by joining furnaces No. 1 and 2 and including the 21-ft. space between them, which gave a furnace 51 ft. long, and of the original width of 56 in. In a similar manner furnaces No. 3 and 4, and No. 5 and 6 were united; at present there are three large-sized furnaces, each 51 ft. long, and one furnace 180 in., or 15 ft. long. At the slag-door level are seven fore-hearths or settlers, as arranged for the original furnaces, which serve equally well for the enlarged furnaces, there being two fore-hearths for each. A matte-track, at a lower level, serves to bring in the matte-ladles, into which the matte of the fore-hearths is tapped. The large blast-furnaces, 56 by 612 in. tuyere dimensions, have side boshes of 8 in., making the width at the throat 6 ft. There

*Interior of Blast Furnace at Hearth-Level.*

is no end bosh. There are two tiers of jackets, each 7 ft. 5 in. high. In either row, and on either side, the three central jackets are 7 ft. wide each, and the four remaining ones are 7 ft. 6 in. each, making thus the total length of 51 ft. The concrete foundation is surmounted by the two original crucibles, to which was added the connecting bridge, the latter formed of water-cooled plates supported by short jack-screws. The crucibles, or sumps, as they may be aptly called, slope to the tap-hole. The bridge portion has a hearth sloping either way from the centre to the crucibles. Thus the total drainage gravitates to either tap-hole. It may happen that the hearth becomes obstructed so as to throw more of the flow to one of the crucibles and less to the other. Such a result, however, need not interfere with the effective operation of the fore-hearths. Both crucible and hearth are made of silica brick, which has been found to be very enduring with the 40% silica slag here used. Above the upper tier of jackets, comes the heavy mantel-plate, 2 ft. 3 in. high, having a sloping front, and surmounted by the apron or receiving plates, 21 in. high, with a slope of 45 deg., both together making a hopper upon which the charge slides down, tending to keep the finer charge closer to the walls, and the coarser material at the centre of the furnace, all of which tends to promote regular working.

The furnace has a closed top, the fumes being carried off by three down-takes to the large dust-chamber adjoining the blast-furnace building. There are 46 tuyeres at the back, and 42 at the front side of the furnace, or 88 in all, set at 14-in. centres. The space supplementing the lesser number of tuyeres at the front is utilized to make room for the two slag-spouts. It is customary to plug, or leave off, the four tuyeres nearest the ends of the furnace, as this is found somewhat to prevent accretions, so that, practically, only 84 tuyeres are used. The omission of the two tuyeres over the spouts does not appear to interfere with the proper operation of the furnace at this point, all of which indicates irregular working of tuyeres. Where it has been undertaken to cut out every other tuyere, the furnace has not worked so well. This, indeed, may be due to the fact that some of those tuyeres cut out were in good working position, or, rather, that the more frequent tuyeres mean more chances of getting air into the furnace. The tuyeres are punched several times on a shift, and it can hardly be supposed that all the air enters the furnace by the small 1-in. hole thus formed. No doubt a good deal gets in between the jacket and the crust, eventually finding its way by devious passages (those of the least resistance) to the interior of the furnace.

The bustle-pipe extends completely round the furnace, and has two branches from the blast-main, each with its own shut-off gate, so that, to shut down the furnace, two valves must be closed. The tuyere pipes are 6 in. in diameter; the jacket opening being 4 in. in diameter, bolted to the jacket for easy removal in case of necessity. The connection to the blast-pipe is made by a galvanized iron sleeve, with a ring-clamp to make the joint tight. The fore-hearths, or settlers, of the former smaller furnaces serve equally well for the large ones. They are 16 ft. in diameter and 5 ft. high, the matte-tap being 3 ft. below the top of the fore-hearth. The slag enters on the side adjoining the furnace, and flows out on the opposite or front side. Experiments at Great Falls show the best point of outflow to be opposite the point of entrance. The discharging slag flows down a steeply inclined spout, which delivers it opposite a 6-in. flattened water-jet situated just below the floor. This is supplied by jacket and other water. Besides this, there is a flow of water from the encircling cooling-pipe of the fore-hearth, which contributes to the stream which sweeps away the granulated slag through a semi-circular cast-iron lined launder,

and conveys it to the dumping-point on the flats below the works.

The exterior of the furnace, having so long a side-wall, is braced and prevented from bulging by ties, carried around the furnace both at the level of the top of the lower jacket, and also under the floor. The horizontal pull of this bracing at the corner posts of the furnace is resisted by inclined ties attached to the floor above at adjoining corner posts. Between the three panels forming the length of the furnace, the jackets are supported by I-beams of the length of the panel (22 ft.). Two sets of the I-beams are to resist outward pressure of the jackets, the upper and heavier sets to hold up the upper jackets when the lower ones have, for any reason, been removed. Two of the outlet or down-take flues, soon to be changed to resemble the central one, are of brick and have hopper-bottoms for the removal of the flue-dust. The third, or central down-take, has an upward and then a downward slope, having a pitch so steep that no flue-dust can rest upon it. Flue-dust, on the upward sloping flue, slides back to the furnace; on the downward sloping side it goes to the dust-chamber.

The dust-chamber, 40 ft. wide and 280 ft. long, is provided with sheet-steel pyramidal hoppers, by which the flue-dust is conveniently drawn off to the charge cars when they are run in below. This chamber, 20 ft. high, affords a liberal space for the settling of the flue-dust. It is connected to the stack by means of a flue of 20 by 15 ft., or 300 sq. ft. area of cross-section.

The furnace is charged through seven doors on each of the long sides, giving access to the entire length. It also has end doors for barring out. The charge is brought in by a train of 18 cars at a time, each car holding 2.5 tons. Eight of these cars constitute a charge amounting to from 18 to 20 tons. The coke is charged separately in two-wheeled buggies, each of 30 cu. ft. capacity, and capable of holding 900 lb. The amount used is 10% of the charge.

The weighing of charges to an 18-car train is thus performed: The cars are spotted to the coarse-concentrate bins, where the specified quantity is weighed in (to two at a time), the flow being controlled by a slide-gate operated by hand. A swinging chute, operated by a compressed-air cylinder, also assists in controlling the discharge. After the concentrates, the 18 cars are simultaneously charged with the briquettes. The train is then taken to the first-class ore-bins for the next item of the charge, then to the slag-bins, and the limestone-bins. It will be seen that, in this way of putting in the materials, the finer portion is at the bottom of the car, and it is so charged into the furnace that it falls to the near side, while the coarser material goes to the centre portion of the furnace.

The temperature of the gases from all the furnaces, in the flue just beyond the dust-chamber, drops as much as 62 deg. C., and the draft-pressure drops 0.2 in. of water when six of the 46 doors are open. The air, with a draft-pressure of 1.7 in. in the flue, has a velocity of 1.5 ft. per sec. through the doors (each of 20 sq. ft. area), and, with six doors open, an admission of 10,800 cu. ft. per min., or one-fifth of the total out-going gases. The quantity entering is proportional directly to the number of doors opened. Of the total heat developed by the burning of the coke and sulphur, 18.6% escapes in the outgoing gases, which, at the entrance to the down-take, have a temperature of 380 deg. C. Not more than these six doors need be opened at any one time, either for charging or for cutting accretions or crusts from the furnace.

THE scientific spirit is of more value than its products and irrationally held truths may be more harmful than reasoned errors.

Drift Mining By Shaft.

Written for the MINING AND SCIENTIFIC PRESS
By D'ARCY WEATHERBE.

(Concluded from page 118.)

The system of timbering is simple and appears efficient. Fig. 6 is a cross-section of the timbering in the main working drifts; two uprights or posts from 8 to 12 in. diam. and 5 ft. 8 in. or 5 ft. 9 in. high, are placed 5 ft. apart at top—inside measure. A cap of the same size is placed across the top of these and a plank sprag underneath it, to resist side pressure; sills are rarely used, though often two sets of posts and caps are placed together to take the heavy pressure. Fig. 7, which is a longitudinal section, will explain the method of driving

a small engine for electric lights (150 lamps capacity). A new Cornish pump of larger capacity is shortly to be installed and a new engine to run it. Wood costs \$4 per cord and oil \$1 per bbl. delivered. About 25 men are employed at the mine, 18 of whom work underground. This number will be increased when more working faces are provided by extension of the development work. The gold-saving and clean-up plant is automatic, the method being somewhat different from the ordinary.

Fig. 8 and 9 show the arrangement. In the first it will be seen that the ore from the skip is dumped into the hopper, which is at the top of the head-frame—about 90 ft. above the shaft-collar. Into this hopper a jet empties the discharge water from the mine and washes the gravel through the trommel, the oversize passing out onto the

Fig. 10.

lagging. Across the top of the cap a 'bridging' plank is laid flat, on top of wedges called 'keys'; under this bridging plank the lagging planks, two inches thick, are driven, knocking out the wedges and resting on top of the bridging plank of the set ahead. The method in the breast-drifts is similar, but the posts are placed vertically and are about 4 to 5 ft. apart. The lagging is driven in the same way as described above.

The flow of mine-water is heavy and the plant includes two steam-pumps, a Dow pump, 10 by 7 by 7½ in. and a Worthington, 12 by 7 by 12 in., and a Cornish plunger 10½ in. diam. and 5 ft. stroke. The Cornish pump is in use for about one hour per day and the Worthington runs the rest of the time. The Dow is an auxiliary in case of accident.

On the surface, the equipment consists of a 60-h.p. oil-burning boiler which supplies steam for an engine to run the Cornish pump, the trommel, a single-drum hoist, and

Fig. 11.

dump while the fine is delivered through the perforations to the sluices. The trommel is 14 ft. long and constructed as shown in Fig. 11. It is divided into an unperforated portion 9 ft. long at the top with angle-irons inside to disintegrate the gravel; a section, 3 ft. long with ½ in. holes and an end section of 2 ft. with four oval-shaped holes to let out the larger rocks. The riffled sluice is double (See Fig. 10) and 132 ft. long over all, with a pitch of one inch per foot. Each division is 16 in. wide and 10 in. deep, and carries a small 'mercury surface' riffle at the top; then come 12 ft. of cross-riffle, the remaining length being fitted with angle-iron riffles placed with the bars lengthwise in the sluice. The upper 12 ft. of the sluice are cleaned up every four days and the general clean-up takes place each month. The riffles, commencing at the top, are taken out and washed onto the sluice, the larger stones being picked and washed off. The residual sand, mercury, and amalgam is then taken to the clean-up room.

The clean-up apparatus is shown in Fig. 12; *a* is an iron clean-up barrel, 3½ ft. long by 2 ft. diam.; *b b* are amalgamated copper plates 4 ft. long and 2 ft. wide each; *c* and *d* are mercury traps and *e* is a sluice 11 in. wide 5 in. deep and 11 in. long with cocoa matting on the bottom. The material is put through this process once a month after the general clean-up. The sand and mercury collected from the sluices are placed in the barrel *a* with iron balls, water, and an excess of mercury. This is rotated by means of the pulley wheel *a*¹ for 14 hours. The pulp is then drawn off at *a*² in a bucket, the slime being allowed to run over the plates first, then the remaining pulp is dumped on the upper plate and the hose turned on.

About 90% of the amalgam is caught in the mercury trap at *c*, the other 10% being collected from the upper plate. Some platinum is secured on the trap *d* and on the cocoa matting below. I was informed by the manager that the tailing contains no appreciable gold. The gold is fairly coarse; occasionally it is found attached to fragments of quartz. The gravel is said to carry about \$3 per cu. yd. and the working cost is estimated at about \$2 per yard.

Bell Signals and the Hoisting-Engineer.

The best hoisting-engineer is he who is not only familiar with every part of the machine in his charge and its peculiarities, but with the shaft of the mine as well—preferably a miner who has worked in the shaft, and who knows every foot of it from collar to sump. He should know every station; its size, and the arrangements for handling ore and timbers at each; every bell-pull at all the various levels, and how they work; also the loading devices at each pocket beneath the levels. Complete familiarity with these details gives him an understanding of the wants of the men below as indicated by their bell-signals, that no mere mechanical observance of the bell-taps can convey. It should not be required of him that he interpret the significance of fitful jumps of the signal-hammer when it fails to strike the gong, but familiarity with conditions in the shaft hundreds of feet below the surface makes him far better able to understand all signals, whether properly given or not—for there is a vast difference in the manner in which different men ring the signals. One man rings deliberately, spacing his strokes and pauses with mechanical accuracy another gives the bell-cord a succession of quick jerks, the strokes not being properly timed, and the pauses scarcely defined from the intervals between the consecutive strokes.

The foreman is at the 800 and desires to go to the 500-ft. level. The skip is rising rapidly from the 1,000 level. As it approaches the 800 he rings one bell; the skip quickly comes to a standstill. He rings eight bells and the skip, running slowly, stops at the 800. He then rings steadily five strokes on the gong; pauses the interval of a stroke, rings three more strokes, steps aboard the skip and gives one more final pull. The skip rises quietly and at the 500 comes to a stop, and the foreman goes about his business. This is as it should be, and the engineer knows he has hoisted the foreman from the eight to the five—he knows him by his ring. On the next trip down, the skip is rattling along at a lively rate nearing the 500. There is a sudden clang of the gong—another, a pause, then two more strokes, but the engineer has his eye on the tin star that scintillates beneath the gong and he knows that the man who is responsible for this disturbance pulled the bell-cord five times, but he is careless, and the third pull failed to register in the engine-room. He is the tool-nipper and he wants to go below. “Crazy Jerry,” mutters the engineer as he shifts the throttle and throws on the brake. Meanwhile the men at the bottom

of the shaft are ringing a loaded skip of rock away in the adjoining compartment. To this the engineer pays no attention until he has got Jerry aboard for his journey below the 500. He then throws in the clutch and as Jerry goes merrily downward, whistling the “Good Old Summer Time,” the loaded skip ascends in the next compartment. When Jerry reaches his destination, the clutch is thrown out and the loaded skip continues its way upward without a balance.

But it is when the skip must be moved slowly and carefully, as when unloading heavy timbers or long rails at a station, handling shaft timbers, or in the event of an accident, when injured men are to be handled, that the engineer who thoroughly understands himself and his charge is worth his hire. An absent-minded man has no business at the brakes, still such men are occasionally found in this responsible position because they are “sober and steady.” The latter are excellent recommendations for any man, but they do not outweigh the defect of absent-mindedness in a hoist-runner. Imagine a hoisting-engineer who forgets within a minute what signal had been given him when he started the skips. Those below ground depend absolutely on the engineer for their safety, and of all the bad traits of hoisting-engineers, that of absent-mindedness is the worst, barring drunkenness. No man should be allowed to touch a hoisting-engine when in any degree drunk. The men working underground should all understand the bell-signals and be instructed in the manner of ringing. The bell-signal system should be as near perfection as possible. Men, whose work is mostly done in the shaft, such as skip-tenders, pump-men, tool and powder-men should all be admonished to exercise care in ringing signals. It is bad practice to yell out warnings of danger from moving skip or cage if the bell-line can be reached—pull the cord. One bell means stop if in motion, either up or down, and is quickly done.

THE FORMATION OF COAL.—The general results of the present inquiry into the transformation of vegetable matter into coal may be summarized as follows:

1. The change from peat to lignite, lignite to bituminous coal, and bituminous coal to anthracite is a process of fractional distillation due to heat.
2. The heat may be applied locally and with great intensity as in a case of volcanic action, or it may be imperceptible but applied throughout a long period of time.
3. In the latter case the action is slow and of such low intensity that it is controlled largely by conditions which accelerate or retard the process.
4. The principal condition controlling distillation of this character is the porosity or impermeability of the rocks which permits or retards the escape of the gases that are formed in the process.
5. Porosity may be due, either to coarseness of grain or to fissures. Where great masses are involved the former has little or no effect as the rocks are practically impervious, therefore, the latter is the great controlling condition of metamorphism. Fissures are produced by joints and by cleavage, and where these are found the coal is in a high degree of carbonization; where they are absent it is changed only slightly from the original peaty condition.—*Mines and Minerals.*

WOLFRAMITE is a tungstate of iron and manganese. Hubnerite is essentially a tungstate of manganese alone. These two minerals resemble each other, the first, however, is usually dark gray, while the latter is brownish red to nearly black. Scheelite is a tungstate of lime, it is very heavy, yellowish white and possesses a dull adamantine lustre. Scheelite is often associated with gold-bearing quartz; this association has been noted in Oregon and New Zealand.

Winning Gold---A Historical Note.

That gold was one of the earliest metals known can scarcely be questioned, for, occurring naturally in the metallic state, its bright color and lustre were well calculated to attract the attention of primitive man and must have led him early to apply it to his needs, both for use and adornment. The first methods for the obtaining of gold, neglecting the infrequent large nuggets which might be picked out by hand, were simply a natural modification of the action of the streams, among the sand and gravel of which the gold occurred. Observing that the gold was exposed in riffles where the lighter sand had been carried forward by the action of the current, it was no difficult task to learn by experiment so to control water currents as to carry away the lighter material occurring with the gold, leaving the heavy metal behind. This was the first, and for a long time the only method; and in its various forms, as panning, the use of cradle, long tom and sluicing, is still of great importance, especially in the development of new districts. In fact, it may be said that in general the history of any mining district is a brief resume of the history of mining as a whole.

The earliest detailed account of gold mining and milling operations is by Pliny (75 A. D.) who describes three methods, the washing of stream sand and gravel, the excavation through shafts of what seems to have been deep gravels, or the soft gossan of a vein, with subsequent washing, and the undermining of large areas which were then caused to cave by cutting away the timbering. Water for these purposes was brought in aqueducts elaborately constructed at great expense, and he also describes the use of sluices cut in the bedrock and covered on the bottom with the branches of some plant, the identity of which is not now known.

An easy improvement of such operations is to employ some form of cloth to catch and retain the fine particles of gold as they are pushed and carried along the bottom. How soon this improvement was made cannot be known, for the next trustworthy account of such operations is that of Agricola (in 1561), who describes methods that had evidently, at that time, long been known.

The invention of stamp-mills is one of permanent importance in the development of the gold-milling industry, for with the primitive methods of crushing, the treatment of hard ores was difficult and laborious in the extreme. This important improvement had its inception in Saxony about the beginning of the sixteenth century, followed later by its application in the Hartz and in Cornwall. Much difficulty was experienced in crushing the hard ores even with stamps, as first employed, and the custom of igniting the ore and quenching with water to make it more brittle is shown by the accompanying illustration taken from Agricola.

Just what part mercury played in this early metallurgy of gold is not quite clear. Although Pliny speaks

of it as an excellent refiner of gold, since the latter alone sinks in it, while the impurities are floated off, yet he does not make any mention of its being used to collect the gold from the concentrate obtained by washing, although stating that the concentrate obtained by a second method was melted down in crucibles. Whether actually employed at that time, it must have been early in use, since the great usefulness of mercury, in collecting gold which is too fine to be readily obtained by washing, is easily perceived.

During the dark ages slow progress was undoubtedly being made in Galicia, Portugal, and the mining districts of central Europe, in the course of which the use of mercury in the treatment of silver minerals must have been developed, for when the rich silver ores of Mexico were discovered, about the middle of the sixteenth century, processes somewhat similar to those which still survive in the *patio* and related processes were quickly put into practice. On the other hand, operations similar to those in use in the New World were tried in Europe without success until a much later period. The exact relation of the New World to the Old in this regard is therefore not completely clear.

When, about 1830, the gold-bearing areas of the southeastern Appalachian region began to be exploited, all the then known processes for the recovery of gold were employed. The highest types of milling processes were the

use of stamps for crushing and of blankets to catch the gold, the practices being patterned after those then employed in central Europe. The chemical processes for the recovery of gold, either had their inception or were greatly stimulated in their development at this time. Some years later, when gold was discovered in California, and economic development of Colorado began, the experience gained in the Appalachians, as especially Georgia, served to direct improvements along such lines that progress was phenomenally rapid; indeed, nearly all the older methods were developed to a much higher state of perfection than they had previously enjoyed. In addition, many new ones were devised, as the legions of patent amalgamators and amalgamating processes, now chiefly surviving only in the patent office records, bear witness. Chiefest in importance is the use of hydraulic giants, amalgamated plates, and in later years of dredging processes.

If limestone is solid, and does not crumble too readily, it may be used in making concrete, but either granite, greenstone, quartz or other hard and less readily soluble rock is better. Before use it should be screened as it comes from the quarry, to rid it of all fine, and the rock, whether limestone or any other kind, should be washed free from dust and dirt before going to the mixing bed or machine. Dirt and organic matter tend to decompose, and consequently disintegrate, concrete. Rock containing sulphide minerals is particularly objectionable, as in time the sulphide will decompose and the sulphuric acid will attack the lime of the cement.

Quenching the Ore After Heating, in Order to Make It Brittle.
From Agricola, about 1546.

Minas Prietas Reduction Works.

Written for the MINING AND SCIENTIFIC PRESS
By MARK R. LAMB.

In the neighborhood of La Colorada in the State of Sonora, Mexico, are situated two silver-gold mines and reduction works. The Grand Central is leased by Chas. Butters & Co., who have been cyaniding the ore directly as it comes from the stamp-mill, but are now considering concentration. The Creston-Colorado Co. uses the Boss continuous process of pan-amalgamation with subsequent cyanide treatment for the sand and slime. The ores of the two mines are similar except in their tenor of precious metals. The Creston-Colorado mine is in bonanza, while the Butters Co. is taking low-grade ores from old stopes.

Grand Central Mill.

It might be well, in passing, to speak of the conditions which govern the present size and arrangement of the plant and control operations at the Grand Central.

The Butters plant was erected originally to treat a pile of tailing which had accumulated for eight years below a mill of 30 stamps and 10 Huntingtons, with pans and

Detail of Guides.

settlers and Frue vanners. The tailing averaged 60% slime, and the slime and sand-plants were proportioned to work material of these percentages. With change of material due to different treatment in the mill, the plant has a capacity for a greater proportion of slime than is now produced. The present tailing runs about 38% slime. About a year before the accumulated tailing was worked, the mill was closed down by the Grand Central Co. for lack of profitable ore. About the time the stock of tailing was exhausted the Butters Co. completed an arrangement with the owners of the mine and mill and shortly afterward they were producing pulp for the cyanide plant.

The mine is worked by Mexican labor entirely, the drillers receiving an equivalent of \$1 gold for six feet of drill-hole. The ground stands fairly well, though some stopes are heavily timbered, and with pine worth four cents per foot, the cost of square set is rather high. The ore is broken into a well-arranged system of chutes,

whence it is trammed to the shaft and hoisted to the breakers. An Otto tram transports the broken ore to the mill, a distance of 1,200 ft., for four cents per ton. The 30 stamps are in excellent condition after having run for ten years. The battery-frame is of iron throughout, and is set upon a massive foundation of concrete. Bolts do not loosen, battery-posts do not rot and require replacing, mortar-blocks will never require replacing and to one accustomed to wooden frames it is simply perfection. The stamps weigh about 850 lb.; they make 96 six-inch drops per min., and crush through screens of $\frac{1}{8}$ -inch aperture. From the batteries the pulp is elevated to the Huntingtons. The pulp from these passes through 60-mesh slot-punched screens on its way to the cyanide plant. The water used in the mortars and re-grinding

Detail of Battery Frame.

mills is cyanide solution carrying 0.02% cyanide, and a few cents gold and silver. Water costs in the neighborhood of 75c. per thousand gallons. The ore upon arriving at the cyanide plant is raised by a wheel-elevator and runs thence to the sand-collecting vats. These have

Detail of Top of Frame.

three side-overflow gates provided with curtains the upper edges of which are kept slightly below the surface of the water when filling. The pulp is introduced and spread evenly over the tank by Butters distributors, the sand settling and the slime running off. This overflow passes through a classifier which separates any accidentally contained sand and returns it to the wheel. The slime goes to a large set of spitzkasten which makes a product about 35% dry-slime and discharges clear water which is used for washing and in the mill. This water is returned to the mill tank through 600 ft. of 3-in. pipe, against a pressure of 63 lb. by a centrifugal pump of 18-in. disk, with 4-in. discharge. The quantity of water raised reaches 200,000 gal. per 24 hr. Weak solution and water washes are added to this mill-water before it is pumped.

The sand is given a preliminary treatment in the collecting vats and is then shoveled to lower vats and given a final treatment with strong, weak, and wash solutions.

The aeration received during transference is believed greatly to enhance the extraction, particularly of the silver. The leach from both sand and slime is brought to the precipitation boxes, which are electrical, and have been fully described by Mr. Hamilton in a paper before the Chemical & Metallurgical Society of South Africa. The anodes of these boxes are of sheet-lead, peroxidized, and the cathodes of sheet-tin. The current density, 5 amp. per sq. ft. of anode surface, is such that the metals are deposited in a pulverulent, spongy layer. After a period dependent upon the value of the ore, but generally three times per month, the division of the box through which the leach from the sand passes is cleaned up. This clean-up consists of sliding a pair of brushes over the surface of each cathode, draining the box, gathering the gold and silver slime, drying, and melting. The product from this box is about 60% metal, the balance being lime and silica. This percentage varies, however, within wide limits. The lime comes from the mill, where it is added to neutralize acidity. Electrical precipitation is by no means as perfect as it might be, as a practical substitute for zinc. The anodes of lead are certain to corrode, however carefully they may be peroxidized. The electrodes are spaced $2\frac{1}{2}$ to $3\frac{1}{2}$ in. to avoid short-circuiting, although this occurs occasionally even at these distances. The lead plates, with the present arrangements at this plant during clean-up, require considerable handling, which unavoidably cracks the peroxide coating and shortens the life of the anode. With cone-shaped vat-bottoms, the anodes should last much longer. Experiments are now being carried on at the Virginia City plant of Chas. Butters & Co. with a view to using carbon plates in lieu of lead, with very encouraging results.

The precipitate from the electrolytic boxes is fluxed with silica and borax, and melted in pot-furnaces. It is considered feasible to melt this slime in a reverberatory furnace in a bath of lead, and to cupel the resulting base bullion. Coke for the pot-furnaces is high-priced and, as wood could be used as fuel in the reverberatory, the saving in fuel would be considerable.

Besides this saving there would be a decreased loss in dust, greater ease and speed in melting, and a finer product for final shipment to the States. Formerly the slime was treated by decantation, but a Butters filter-box has been recently installed which permits of a more thorough washing of the slime and a consequent better saving of metals and a less loss of solution.

CHALCHIHUITL, a name celebrated in Mexican archaeology, was applied to certain green stones capable of high polish, which were carved into various ornamental forms, and very highly valued. There has been much mystery and much discussion as to what this precious material really was, and whence it was obtained. It seems evident that several minerals were included under this name—among them a green quartz or prase, some of the deeper green varieties of *tecalo* or Mexican onyx (so called), and probably turquoise; but the precious *chalchihuitl* has now been proved to be jadite, a stone which has possessed a singular charm for many aboriginal peoples in widely separated parts of the globe, but which, for some reason, has not so much attracted the notice or the taste of the historic races.

THE Russian Government, realizing the proclivity of laboring men toward drunkenness, makes, for the benefit of the employer, a law requiring a man hired on contract to work continuously for a period of six months or a year, and he is not paid until the end of that period. Without it, it would be impossible to get any continuous work done by the Russian laborer in Siberia.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

The black rock from Kendall, Mont., marked E. L. B., is Quartz-mica-diorite.

The mineral specimens from Hardscabble, Utah, are determined as follows: No. 1, Magnetite, with disseminated chalcopyrite (copper sulphide); No. 2, Pyroxene; No. 3, Magnetite, with a little copper carbonate. No. 1 and 3 are probably from the gossan of a copper-bearing vein, and should be explored by sinking.

The minute crystals from Happy Camp, Cal., are Zircons—silicate of zirconia—thus described by Dana: Crystallization, tetragonal; fracture, conchoidal; brittle; hardness, 7.5; gravity, 4.7; lustre, adamantine; colorless, pale yellowish, grayish, yellowish-green, brownish-yellow, reddish-brown; transparent to opaque. The heavy sand from the sluices should be collected and carefully tested for the presence of other rare minerals, such as thorite—silicate of thorium, monazite, etc. Zircon is valuable for its zirconia content, which is utilized in the manufacture of the Nernst electric lamp.

The rocks from Lyons, Kan., marked J. A., are: No. 1, Diabase. The fine material in No. 2 is evidently a much altered and silicified greenstone containing pyrite. The soft material is clay and talc.

The rocks from Bodfish, Cal., marked C. E. H., are all Grano-diorite in various stages of alteration. No. 1 is silicified and contains much disseminated arsenical-iron sulphide; No. 2 is still more silicious and is impregnated with pyrite; No. 3 is in an intermediate stage of alteration, and contains finely disseminated mispickel; No. 4 is similar and contains both pyrite and mispickel.

'ROLLED GOLD' is a cheap substitute for solid gold, used for jewelry, and consists of brass covered on one side with a thin coating of gold of any of the recognized standards. It is made by brazing a thin plate of gold on to a thick plate of brass, and then rolling the ingot out into thin sheet from which the articles are manufactured. The gold covering may be of any quality or thickness. Gold of 9 to 10 carat is the usual quality, but better qualities are also extensively used. In the best qualities the gold is sufficiently thick to bear engraving without cutting through into the base metal. Rolled gold is mostly of German origin, but it is also manufactured to a considerable extent in Birmingham, England. Before being placed on the market, articles of the poorest quality of rolled gold are 'dipped' in order to improve their appearance, but the thin coating of gold thus obtained soon wears off. When the brass is covered with gold on both sides it is known as 'filled gold.' Watch-cases of filled gold are made in America, and at Birmingham, England. The advantages of 'rolled' and 'filled' gold over electro-gilded articles is that the coating of gold on the former is much harder and thicker.

THE vanadium minerals—descloizite and vanadinite, both of which are vanadates of lead—are used as oxidizing agents in dyeing. Descloizite from the Globe district, Arizona, is exported to Germany for this purpose. Chromite, at present mainly employed, is being replaced by the vanadium salts because the latter can be regenerated, while the former is consumed.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

METALLURGICAL APPARATUS.—No. 823,561; E. A. Touceda, Albany, New York.

In a metallurgical apparatus, the combination with a fuel-burning metallurgical furnace; of an electric heater located within said furnace; an electrical generator connected with said electric heater, and a generator-operating motor operated by heat emanating from said furnace.

ROASTING-FURNACE.—No. 824,181; Frank Klepetko, New York.

In a rabble apparatus, a hollow shaft and hollow arms therefor, means for circulating a body of water through a section of the shaft and corresponding portion of the arms, means for circulating steam generated therefrom through another section of the shaft and portion of the arms, and inlet means and outlet means for the circulating mediums.

ROCK-DRILLING MACHINE.—No. 823,980; Cassius M. Walker, Pueblo, Colo.

The combination of the casing, piston-hammer, piston-chuck, means for supplying fluid under pressure to reciprocate the hammer, an exhaust, means for throttling the exhaust, a cleaning-tube, a valve-controlled channel and ports whereby the exhaust may be conducted to said tube, and a valve-controlled channel and ports whereby the live pressure may be conducted to the cleaning-tube.

CONCENTRATOR.—No. 822,912; Martin P. Boss, San Francisco, California.

In an endless-belt concentrator, adjustable controlling-rollers relatively disposed to the belt to counteract by their change of inclination, the lateral crawl of the belt, in combination with mechanism actuated by the traveling belt, itself, in crawling, to effect the adjustment of said controlling-rollers, consisting of a pair of relatively oppositely arranged revoluble cam-contacts upon the receding faces of which the

sides of the belt impinge to momentarily turn them, one of said cam-contacts being on each side of the belt, connections for operating said cam-contacts in unison, and suitable connections from said contacts to the controlling-rollers.

ORE ROASTING FURNACE.—No. 824,263; Charles H. Rider, St. Louis, Mo.

In an ore-roasting furnace of the class described, a roasting-chamber provided with inlet and outlet doors in one wall, an obliquely-disposed cylindrical retort arranged for rotation in the chamber, heads fixed in said retort in one of which heads is formed an opening so located as to coincide with the openings in the wall of the chamber, and a plate normally closing said opening.

SETTLING TANK.—No. 824,279; John M. Callow, Salt Lake City, Utah.

In a settling device, a funnel-form tank, a ring placed interiorly of said tank and forming with the wall of the tank a channel therein, said channel provided with outlets and a bottom inclining toward said outlets, a band of flexible material supported upon said ring and means for tightening or loosening said band whereby said band may be variably adjusted at different portions of the circumference of the ring to secure a perfectly level overflow.

ORE SEPARATOR OR FILTER.—No. 824,905; Claus P. Christensen, Bullfrog, Nevada.

An apparatus of the class described comprising a main supporting frame, a pair of belt pulleys mounted in bearings at each end of said frame, means for adjusting one of said pulleys, an endless separating belt passing around said pulleys, said belt having raised portions at each side thereof, a supplemental supporting frame mounted on the main supporting frame between the belt and the belt pulleys, a water-receiving trough mounted on said supplemental frame below the belt, belt-supporting rollers over said water trough, means for depositing the materials to be separated on said belt over said water trough, a receptacle at one end of the main frame for receiving the solid matter from the belt, a guide roller on the main frame over which said belt takes, a tamping device supported by the main frame for tamping said belt to remove the solids therefrom, drive mechanism for said belt, means connecting said belt-drive mechanism with said tamping mechanism to operate the same.

A Modern Tramway at an Old Mine.

Western men do not associate New York State with mining operations, save such as are involved in city subways and tunnels, but it appears that the re-opening of the Old Forest of Dean iron mine, in Orange county, involves many interesting problems. Among others is the tramway. Owing in part to the surface of the country being broken into hills and ravines, and partly to difficulties in connection with obtaining right of way, the railroad could not be carried to the Hudson river. The last 6,300 ft. of the haul to the dock is accomplished by means of an aerial tramway. At the termination of the surface-road, the cars dump into a bin of 500-ton capacity. From this the ore is discharged into a hopper, which delivers it into the buckets as they pass round the loading terminal of the cableway. The wire-rope conveyor was built by A. Leschen & Sons Rope Company, St. Louis, and is of the double-rope type. The cable is carried on 23 towers, and in the distance of 6,300 ft. the ore travels down grade about 390 ft. The capacity of the tramway is 23 tons per hour. The essential feature of the Leschen automatic system is that the buckets are permanently attached to the traction ropes and are loaded by a traveling automatic loader or hopper. This hopper after having been filled from the chute travels alongside the bucket as the latter passes over the rail at the terminal station. After having emptied its contents into the bucket the hopper is returned to the original point under the chute by the movement of a lever. The buckets are so hung in the pendants as to upset easily when tipped, though when in transit they are securely locked by means of a catch to prevent them discharging their contents. At the unloading stations the buckets are discharged by being automatically tripped, and by means of a righting device are returned to their normal position ready for loading. A single operator is required, and he is placed at the bin where the ore is dropped into the automatic loader. At the dock on the Hudson river, a bin of 1,000-ton capacity is being erected. From this the ore can be discharged into railroad cars on a siding of the West Shore railroad, or it may be loaded into boats after being dropped through a chute into a car traveling back and forth on an incline and connected by cable to a drum driven by a small engine. The 1,000-ton bin, according to the original plan, was to be placed at the water's edge, discharging on one side into cars and on the other side into barges. Owing to the fact that the rock underlying the surface clay pitched at a sharp angle toward the river a suitable foundation could not be secured, and the bin was therefore built about 100 ft. back from the water.

Publications Received.

'MECHANICAL DRAFT' by J. H. Kinealy. This little volume treats of the various systems of mechanical draft, forced draft and induced draft, draft under differing conditions; the effect of economizers, draft fans, etc. A book both interesting and valuable to those in charge of steam-power plants. Sent by MINING AND SCIENTIFIC PRESS upon receipt of price, cloth bound \$2. Spon & Chamberlain, publishers, 123 Liberty St., New York City

Trade Treatises.

ABBE ENGINEERING CO., of 220 Broadway, New York, has issued a profusely illustrated catalogue, entitled 'Pulverizers.' It describes the numerous types of pulverizing devices made by the company, including laboratory mills, jar mills, pebble mills, tube-mills, ball mills, crushers and crushing rolls, and others, for both wet and dry grinding, coarse or fine.

HENRY TROEMNER, of Philadelphia, has issued Catalogue B. A. L., describing the Troemner balances—assay, analytical and pulp. The pamphlet is well illustrated, showing the many styles of balances manufactured by this maker, together with the other paraphernalia used in precise weighing in the laboratory and assay office.

THE BUFFALO-FORGE CO., of Buffalo, N. Y., has issued Catalogue No. 97, descriptive of its new air-washer and humidifier, a most useful sanitary device for purifying the air of apartments. The construction and method of operating the air-washer is well illustrated and described by numerous half-tones and line drawings.

Commercial Paragraphs.

WARREN C. BOGUE, Denver manager for THE MINE AND SMELTER SUPPLY CO., is expected to return from Alma, Michigan, where he has been the past three months on account of illness.

CHISHOLM, MATTHEW & CO., of Colorado Springs, has secured the order for Edwards roasters in the cyanide mill now being erected by the Golden Cycle Co., for the treatment of Cripple Creek ores.

THE WELLMAN-SEEVER-MORGAN CO., of Cleveland, O., has received an order for 15 six-foot Chilean mills for the Utah Copper Co., at Garfield, Utah, one of the largest orders ever placed for Chilean mills.

The Pelton-Francis turbine, recently placed on the market by the PELTON WATER-WHEEL CO., has contributed its share to this season's work and is proving a valuable adjunct to the company's business. This is a new departure in water-wheel practice, and is attracting the attention of engineers.

THE COLORADO IRON WORKS CO., of Denver, has lately entered orders for two impact screens for Leadville; one for Kelvin, Arizona; two for Boulder, Colorado; three for Providence, R. I.; two Dorr classifiers for Mexico; a set of Humphrey 27 by 14-in. rolls for Murray, Idaho; and a set of the same type of rolls for Mullan, Idaho; and one 11 by 15-in. Dodge crusher for New Mexico.

THE UTAH MINING MACHINERY & SUPPLY CO. reports having secured an order from the Boston Consolidated Mining Co. for 234 Standard 8-ft. Callow settling and pulp thickening tanks, and 78 dewatering tanks to be used in the concentrating plant that it is now erecting at Garfield, Utah, the order calling for delivery by March 1, 1907. This is the largest order for settling tanks, of special design, ever placed by one company.

THE RISDON IRON WORKS, of San Francisco, reports receiving the largest concentrator order ever placed in the history of the mining industry. Last year the Utah Copper Co. gave an order for 80 machines of the Johnston type, with certain improvements and modifications which have recently been applied to them. Before the 80 machines were delivered it received a further order for 1,104 machines. It also has an order for 234 machines from the Boston Consolidated Mining Co. of Utah.

L. VOGELSTEIN & CO., New York, reports that the German consumption of foreign copper for the months January to May, 1906, compared with the same period in 1904 and 1905, was:

	1906.	1905.	1904.
	Tons.	Tons.	Tons.
Imports	51,962	42,744	47,231
Exports	5,059	5,324	3,250
Consumption	46,903	37,420	43,982

THE success with which wind-mills have been used for pumping and drainage purposes in Holland, and in many places on the prairies of the Western States, leads one to believe that they could be used for the same purpose in mining. They are but little used in connection with mines; that is, perhaps, due to their unreliability, and to the fact that most mines are situated in mountainous districts, where, owing to the excessive force of sudden gusts of wind, wind-mills would be liable to serious accident, if not to total destruction. Thus, with a pleasant breeze of 10 miles per hour we have a pressure of 0.5 lb. per sq. ft. but with a hurricane of 100 miles per hour the pressure has gone up to 100 times the first pressure or to 50 lb. per sq. ft. That is, the pressure increases as the square of the velocity.

Editorial.

THE AMERICAN MINING CONGRESS will hold its annual session at Denver on October 16 to 19, inclusive. Among the matters to be discussed will be the report of the Committee on Mine Drainage Districts and the prevention of mining frauds. Another subject to be ventilated is that of damage due to smelter fumes. The Secretary, Mr. James F. Callbreath, Jr., will be glad to receive suggestions such as may contribute to the usefulness of the convention.

IN OUR LAST issue we outlined the probable control of undeveloped coal lands by the Government and the impracticability of the alternative project, of coal mining by Government, in order to influence trade conditions. It appears that this forecast was correct, for during the last few days the Secretary of the Interior has issued an order withdrawing from entry six million acres of public lands which are known to possess workable coal. This will enable the Government to study the coal situation in relation to the monopoly of a great natural product. It is likely that the step will provoke opposition and that its legality will be contested. We hope it may be upheld.

INVESTIGATION OF RESULTS on the Rand indicates that the Chinaman costs from 12 to 15 cents per shift more than the Kaffir. Our contemporary, *South African Mines*, states this to be the experience at a representative group of mines. It is questioned whether the coolie is worth the extra cost, which is due largely to the complex arrangements involved in bringing him to South Africa. He earns less, it is true, in wages, but he costs more to feed, police, and administer. It may not entail more expense to bring him to the mines than the Kaffir, but the yellow man has to be re-patriated while the black fellow shifts for himself. It appears, therefore, that the Chinese experiment is a disappointment, but this is not the same thing as saying that it is a failure, because whether cheaper or dearer than the Kaffir, it is a fact that there are not enough Kaffirs. What the Rand wants is sufficient native labor. Experience in other countries emphasizes the conclusion that importation of laborers is a mistake, so long as the people of the country can be taught to work and secured in sufficient numbers.

IN THE LAST Bi-monthly Bulletin of the American Institute of Mining Engineers, the Secretary refers to certain notes placed at his disposal by a member, who had not the time to put them into shape. In this case the result of Dr. Raymond's work on Mr. W. H. Shockley's material, is, of course, an interesting article. Incidentally the Secretary states his argument that "such recent and trustworthy data concerning a new and important mining industry ought not to be withheld from our *Transactions*, simply because they are not sufficient to

constitute a complete academic treatise on the subject. This argument is recommended to the attention of many other members, who are waiting for the opportunity to contribute something 'monumental' to our *Transactions*. In a number of instances, death has nullified this ambition, and the intended 'monumental' contribution has turned out to be an obituary notice by the Secretary, instead of a valuable record of the professional experience thus hopelessly lost to the world." Which is manifestly true. But the quality of the Secretary's obituaries is so good and the sentiments he puts into them are so excellent that we almost think his memorial literature is more inspiring than the technological monument the other fellow intended to build; the Doctor's obituary is more likely to live than Smith's or Brown's autobiography. Moreover, we would be sorry if many engineers followed Mr. Shockley's example, for it is a hard task to digest another man's notes and it is rarely well done save by the perpetrator himself. Dr. Raymond is a man to whose capacity for work there seems no limit intellectually, and therefore we do not want to see an unnecessary trespass on his physical strength. Hence this friendly protest.

A Fiasco and Its Lessons.

The misfortune of the Fresno Copper Co., Ltd., would not call for comment save for the lessons which it conveys. We have delayed reference to the matter until adequate information was obtainable. The story is a simple one. In 1901 Mr. H. B. Vercoe bought a ranch in Fresno county for about \$12,000. On this ranch there was a shaft 120 feet deep. It was an abandoned copper mine. The ranch and the mine on it became the basis of the California Copper Syndicate, organized at London with a capital of £30,000. In April, 1902, 80 acres were transferred to the Fresno Copper Company for £105,000 in fully paid shares. Some work was done at the mine, and a smelter was projected, so that in July, 1903, the Fresno Company took over the remaining holdings of the Syndicate, namely, 2,360 acres of land and a gold-quartz mine which was to supply silica for the smelter; for these the vendor syndicate received £195,000 more in shares. The Fresno Copper Company had an authorized capital of £400,000; this stock sold recently for over £2 per share, so that the vendors had a chance to clear a large sum of money. Two months ago an independent engineer made a careful examination; on July 13, the secretary of the Company posted a notice on the board of the Stock Exchange at Glasgow, reading: "We are instructed to inform you that Mr. Fred J. Siebert, the expert appointed to examine the mine, has condemned it." The shares fell to two shillings.

When the mine was first taken over there was only one shaft that had penetrated below the oxidized material, into sulphide ore. Down to 90 feet, the workings were in the zone of decomposition. Mr. Vercoe's samples showed an average of about 6 per cent copper. Several other engineers reported on the mine, favorably. Among them was Mr. Herbert Lang, who was retained, as a specialist in copper smelting, to advise on the ore reduction. He accepted Mr. Vercoe's sampling and, on

this insecure basis, he also spoke highly of the showing in the mine. Subsequently, he advised, repeatedly, that the mine be sampled systematically, not only to check the statements made, but to give data required in mixing charges for the smelter, which was built at a cost of £50,000. In April last, Mr. Lang sampled the principal ore-dumps, obtaining an average of 1.7 per cent copper; his report was received at Glasgow on May 26; nevertheless, on June 1, at a shareholders' meeting, a glowing account was rendered by the secretary of the Company, who had just visited the mine, and Mr. Siebert was quoted, correctly, as having formed a good impression of it—this impression to be checked by the sampling he was about to undertake. That sampling eventually gave 1.04 per cent copper and 13 cents per ton in precious metals. It remains but to add that Mr. Vercoe is a mining engineer in good standing, for he is a member of the Institution of Mining & Metallurgy. Where then is the nigger in this disordered wood-pile?

Mr. Vercoe bought the mine as a speculator, he reported on it as a promoter, he became managing director while a vendor. During the five years following the inception of the enterprise, no expert opinion was obtained save that of the vendor and his agents. The engineers were all engaged by Mr. Vercoe; the first proper sampling of the workings pricked the bubble and scattered the iridescent films all over the floor of the Glasgow stock exchange. It is true, the pleasant expectations of the directors were fortified by the opinions of all sorts of visitors, such as the secretary, several of the directors, some of their relatives, more of their friends and even of neighboring mine superintendents; but the estimates of each and all of these people were worthless, because they did not include proper sampling. A copper mine in the oxidized zone is a pretty thing, gay with color and gorgeous to the beholder; but chromatic splendor is not indicative of richness. The directors who came to California and returned to Scotland with a few pretty specimens of copper ore, to have them assayed by some celebrated chemist, were taking part, not in business, but in *opera bouffe*. Systematic sampling honestly done at any time between April, 1901, and April, 1906, would have laid bare the true inwardness of the mine.

Two lessons are to be learned. In the first place, a metallurgical specialist should not report on a mine and, when he does, he should take his own samples. Next, a report is worth about what you pay for it. Investors and directors who accept vendor's reports, get advice that is worth just what they pay for it—nothing. The mine was bought for a few thousand dollars and then capitalized for more than a million, on the advice and management, throughout, of the vendor, the vendor's experts and the vendor syndicate. A fair speculation at \$12,000, it became a ghastly certainty at \$1,500,000. This is an old method, revived. Twenty years ago it was the usual thing to buy mines in America for dollars and to float them for pounds, to take the vendor's statements and to put the vendor's engineer in charge. The Fresno Copper fiasco is an anachronism; such methods are out of date; there is no excuse for them.

By the Way.

It has been said that one man's rights end only where another man's begin. This is the only possible interpretation of equality of rights, of mutuality. This is the spirit in which we should enter upon our contracts. Is this the spirit of the age? The spirit of the age is to obtain some personal advantage, all because of the old idea which is universally rejected and yet persistently applied in action that one man cannot obtain an advantage without injury to some other man. This may be true in war and love, the one a remnant of barbaric days, the other a law unto itself, but it is not true in commerce, and we all know it and all disregard this knowledge. Where commerce is carried on as a warfare and all rules of honesty and morality are ignored, it may cause the over-prosperity of one man through the enslavement of others, but I refer to that class of honest, progressive commerce in which alone all of us are interested.

Every man attaches a great deal of importance to his signature when he endorses it on a check payable to his order, especially if the amount be large. This feeling of importance is intensified when he attaches it to a promissory note or to a sworn statement. The factor which intensifies this feeling of importance we usually call "the sense of honor," and we can take it for granted that the validity and necessity of the sense of honor in such cases is beyond discussion. A contract to sell or to buy goods, is an express executory document, and the principles involved are of the highest order; an easy way for you to realize this is to read carefully the wording of any of your own contracts when it is being broken at your expense. A man's honor is as fully at stake when he attaches his signature to a contract as when he attaches it to a promissory note. If he repudiates or openly or secretly breaks the contract he dishonors his signature. The financial measure of his action, if he be the buyer, is the manufacturer's profit; if he be the seller, it is the difference between the contract and the market prices. A definite sum of money is at stake, and the breach of contract is, therefore, no more nor less than an appropriation of another man's money.

Some men may smile at the legal form which some manufacturers adopt for their contracts. This is not a wholesome attitude. Let your contracts be as simple and as short as possible, but give them a legal appearance, and do not omit the legal phraseology, for that is just what will help you and the person with whom you make the contract to remember that the signature is not a mere dash of the pen, but serious undertaking, in which the integrity of a name and of a reputation are at stake.

A breach of contract is bound to be a most potent demoralizer and a shield for all kinds of malpractices; malpractices which in many quarters are accepted as regular routine business; fixed habits which drug our sense of right during the six days of the week and create a personality, though outwardly active, which selects the easy, but devious method, in preference to that which requires concentration, patience, and Sunday morals on week days. As Franklin once said: "Tricks and treachery are the practice of fools that have not wit enough to be honest."—Alfred Sang in *Industrial World*.

DURING President Roosevelt's incumbency in office 802,000,000 pieces of metal money have been coined in the United States Mint in Philadelphia, according to figures given out recently by Superintendent Landis, who for several weeks past has been hard at work compiling data relative to the output from the Philadelphia Mint as compared with the output from other Government money mills. Superintendent Landis in his report, which

includes the work of the Philadelphia Mint, says that the output of metal money throughout the country is going on without interruption or delay, despite the fact that the money now in circulation reaches \$32 per capita and that the per capita of small change, notably quarters, dimes, nickels, and cents, is increasing steadily. The following statement shows the coinage, by pieces, of metal money manufactured under the several administrations during the past 20 years in Philadelphia: Cleveland's administration, 1885 to 1889, 254,065,293 pieces; Harrison's administration, 1889 to 1893, 358,660,725 pieces; Cleveland's administration, 1893 to 1897, 238,011,174 pieces; McKinley's administration, 1897 to 1901, 540,497,141 pieces; Roosevelt's administration, 1901 to 1906, 802,000,000 pieces. Of the \$82,000,000 in silver quarters coined in the mints of the United States since the establishment of the first mint, the mint at Philadelphia coined \$9,500,000 under the present administration. Of the \$50,000,000 in dimes coined in the United States since 1792 the mint there coined \$8,000,000 under the present administration; of the \$27,000,000 in nickels or five-cent pieces coined, the local mint made nearly \$7,000,000 under the present administration; of the \$18,300,000 in cents coined, the mint at Philadelphia turned out nearly \$4,000,000 during the present administration. In other words, there has been coined at the United States Mint there since President Roosevelt assumed the presidency nearly one-fourth of all the cents coined since the establishment of the United States Mint in 1792; over one-fourth of all the five-cent nickels, nearly one-sixth of all the dimes and over one-ninth of all the quarters.—*Industrial World*.

THE evidences of Mexico's prosperity, under the gold standard, are manifold as shown by statistics in a recent article in *Appleton's Magazine*. There was an increase of three million dollars in the Federal revenues during the first year; the capital of the chartered banks was augmented 20 millions, or 30%, and the reserves of these institutions in the same ratio, thus adding 30 millions to the banking capital of the country and, moreover, the business of these concerns was doubled in that year; there was a gain of 15% in the tonnage of vessels in commission in Mexican waters; manufacturing has been largely expanded, chiefly owing to the utilization of electrical energy obtained from water power; agricultural industries have been promoted, through irrigation, and evidences of Mexico's prosperity are apparent in every part of the republic in the form of costly public improvements. About 150 millions of foreign capital was invested in productive enterprises during the last year; most of the American money was placed in railroads and mines and it is estimated that our holdings in the latter were increased 25 millions, while investments in all enterprises are now 600 millions with the prospect of their reaching a total of one billion in the near future. French capital has also been poured into Mexico and it is noteworthy that in less than one month after the inauguration of the gold standard Paris bankers had secured control of the banking interests of the country through investment in the leading institutions of the city of Mexico. Canadian capital, as well as German, Belgian, Swiss and Italian, is being invested, while very little British money is in evidence. Great Britain is losing ground in Mexico. Apparently she has decided to leave the Mexican field to us and devote her attention to South America. British trade with Mexico has fallen off one-half in the past ten years. Until a quarter of a century ago the British commercial interest in Mexico predominated over other foreign capital in the republic. It now ranks fifth, and is steadily dwindling. Still, over \$100,000,000 in Mexican Government gold bonds are locked up in British safes and are considered as excellent securities.

Special Correspondence.

BUTTE, August 4.

During July there was a reduction in the tonnage of ore mined in the Butte district, but an increase in the pounds of copper produced. There was a general increase in the percentage of copper, especially in the output of the Anaconda, Parrot, Trenton and Red Metal mines. The total copper production for the month was 33,922,370 lb., against 32,576,700 lb. for June, an increase of 1,345,670 lb. The tonnage in July was 436,480, against 437,550 in June. The July production by companies was as follows:

Company.	Tons of ore.	Pounds of copper.
Boston & Montana.....	117,800	8,952,800
Anaconda.....	127,100	9,151,200
Butte & Boston.....	19,220	1,345,400
Washoe.....	17,360	1,249,920
Parrot.....	10,850	672,700
Trenton.....	17,050	1,193,500
North Butte.....	31,000	4,185,000
Red Metal.....	40,300	2,861,300
Original.....	29,450	2,179,300
East Butte (lessees).....	6,200	620,000
Pittsburgh & Montana.....	4,650	348,750
Miscellaneous.....	15,500	1,162,500
Total.....	436,480	33,922,370

Between 16,000,000 and 17,000,000 lb. copper were turned out by the Washoe smelter at Anaconda, and it is stated that with the improvements now being made, the capacity and output will be 20,000,000 lb. per month. The output of the Boston & Montana smelter at Great Falls was about 10,000,000 lb. in July, and that plant is also being enlarged so that it will be able to handle an additional 500 to 800 tons of ore daily.

The East Butte Mining Co. has begun the use of its new engine and air compressor. Sinking, under contract, has been resumed on the main shaft. — The Lewisohn General Development Co. has abandoned work on the Altoona, one of a group of mines and undeveloped claims upon which it has a lease and bond. The old workings are between 300 and 400 ft. deep. The Lewisohns pumped out the water and examined the old workings, but concluded that the showing did not justify further exploration. The company is now sinking a shaft on the Montgomery, adjoining the Bullwhacker, owned by Patrick Clark, of Spokane. The Bullwhacker vein will doubtless also be found in the Montgomery. This vein runs north-south, whereas all other veins in that vicinity, including those of the Pittsburgh & Montana Co., strike east-west and have been traced up to the lines of the Bullwhacker.

Another discovery has been made on one of the claims of the Butte Hill Copper Mining Co., which is exploring ground a mile farther north than any other copper mine. At a depth of 200 ft. a cross-cut has been run 100 ft. through vein-matter, and an 18-in. streak has been cut that assays 3% copper and 20 oz. silver per ton. The find is chiefly valuable in settling the question whether there is copper in that part of the district.

The Butte Coalition Co. is sinking both the Rarus and Corra shafts, and with the Butte & Boston is sinking a new shaft on the Tramway claim, owned jointly by the two companies. It is mining ore in the Minnie Healey, Rarus and Corra, and the Nipper vein is being mined for it by the Parrot Co., the Tramway by the Boston & Montana, and the Belmont by the Anaconda Co. The company is hoisting about 1,300 tons per day, but as soon as improvements now under way are completed, the output will be increased to about 1,800 tons. — The Eagle Mining Co. has begun shipping ore, mined at a depth of 200 ft. The shipments have been yielding from 75 to 100 oz. silver per ton. The vein is five feet wide. — F. Augustus Heinze, who has secured control of a large porphyry dike in the Rimini district, about 18 miles southwest of Helena, will test it by diamond-drills. On

the surface the dike carries \$3 in gold per ton, which, it is thought, can be worked at a profit. — The Butte Copper Exploration Co., which is developing the Six O'Clock group on the east side of the district, has reached a depth of 800 ft., where a station is being cut. This will delay sinking for several weeks, but when the station is completed sinking will be resumed to 1,000 ft., which point is expected to be reached by the middle of October, and then a cross-cut will be run north to the vein.

The shaft of the High Ore mine of the Anaconda Co. has reached a depth of 2,400 ft., where a station is being cut. The shaft will be sunk several hundred feet deeper and will be connected with the workings of all the mines on Anaconda hill for the purpose of draining them through the High Ore. — Re-timbering of the Mountain View mine, of the Boston & Montana Co., has been finished and the mine is yielding the usual quantities of ore. — Lessees are working in ten shafts of the East Butte Co. and shipping 150 to 200 tons of ore daily, the gross returns being \$2,000 per day, of which the company receives 25%. The ore is treated at the Washoe and Clark smelters.

The precipitating plant, built by lessees to work the tailing of the old Parrot smelter, covering about seven acres in East Butte to a depth of 5 to 30 ft., has been started. It was built at a cost of \$25,000. Upon the expiration of the lease the plant will revert to the company, which will get a royalty of 25%. It is announced that when the improvements at the Washoe smelter, now under way, are completed, that plant will be able to turn out 20,000,000 lb. of copper per month. Among the additions being made is a blast-furnace 87 ft. long, eight roasters, two stands of converters, and corresponding increase in all auxiliary facilities.

It is reported that F. Augustus Heinze is negotiating for the Rex group of mines in the Cœur d'Alene country. He already has secured control of the Stewart mines.

SALT LAKE, August 4.

The ore and bullion settlements last week aggregated \$596,500. In the Salt Lake Stock & Mining Exchange for the same period there were transfers of 183,478 shares for \$160,060. — A post-office has been ordered established at Goldsprings, a new mining camp in the western part of Iron county, which has a population of about 50 persons. The Jenny Gold Mining Co., operating there, has developed a large body of milling ore and a mill has been ordered. Charles A. Short, of Goldsprings, is manager.

In Beaver county, the Horn Silver Mining Co., at Frisco, has encountered a new ore-shoot on the 700-ft. level, some distance north of the old workings. It is believed to be an extension of the original Horn Silver vein. The ore is of shipping grade, carrying gold, silver and copper. — The Estella Gold Mining Co., operating near Milford, has completed the installation of a 25-stamp mill. Ore assaying from \$10 per ton will be treated.

Ore shipments from the Tintic mining district this week aggregated 143 carloads, the contributing mines being: Eureka Hill, 16; Centennial-Eureka, 36; Yankee Consolidated, 4; Beck Tunnel Consolidated, 5; May Day, 2; Eagle & Blue Bell, 3; Uncle Sam Consolidated, 4; Bullion-Beck, 6; Gemini, 6; Scranton, 4; Dragon Iron, 13; Swansea, 3; South Swansea, 1; Joe Bowers, 1; Carisa, 7; Mammoth, 10; Ajax, 2; Victoria, 9; Grand Central, 9; Godiva (concentrate), 2. In all the output was about 7,000 tons. The Mammoth Mining Co. is mining rich gold ore from the lower levels of the mine. One lot of 98 tons sold this week for \$12,143, controls showing 6.7 oz. gold and 2.7 oz. silver. — The Colorado Mining Co., Jesse Knight of Provo, manager, has re-commenced development of its property adjoining the Beck Tunnel

Consolidated.—The shaft at the Farragut mine in North Tintic is down 125 ft.—Ore shipments from the Scotia mine in West Tintic are about to begin.—Interesting developments are taking place on the 1,700 level of the Lower Mammoth mine.—A large new compressor is to replace that now in use at the Centennial-Eureka mine in Tintic.—The sinking of the shaft at the Eagle & Blue Bell mine in Tintic district, from 1,000 to 1,500 ft., has been ordered, it is reported, at the instance of F. Augustus Heinze.

Park City mines last week shipped 2,100 tons of ore to Salt Lake smelters, the shippers and respective amounts being: Daly-Judge (ore), 355 tons; Daly-Judge (zinc middling), 287; Daly-West, 470; Silver King, 600; Little Bell, 333; Keith-Kearns, 31; New York, 13; Jupiter, 11.—A raise from the 900-ft. level of the Daly-West mine, at Park City, has encountered the Little Bell fissure.—June was a prosperous month for the Daly-Judge Co., at Park City, returns from shipments aggregating nearly \$50,000.—The Little Bell mine is now shipping ore to Salt Lake smelters, and mine conditions continue encouraging.

The new Garfield smelter of the American Smelting & Refining Co. has begun operation. The plant was 10 months in construction and cost \$2,500,000.—The construction of the Boston Consolidated mill at Garfield, designed to treat 5,000 tons of ore per day, is progressing. Concrete foundations are being put in. It will be 60 days before the first steel for the main mill-building is raised. The power-plant, however, is well advanced.

The Utah Copper Co. is stripping the overburden of its Bingham properties and will have the second shovel going in about two weeks.—At the Montezuma mine, in Bingham, ore of shipping grade has been found in both the north and south drift, and a 12-ft. vein has been cut in a west cross-cut.—An order will be placed for a big hoisting plant for the Ohio copper mine at Bingham, and the mine is to be explored at greater depth under supervision of Thomas Weir, who is supposed to be representing F. Augustus Heinze, owner of a majority of the stock tied up on an option. Mr. Weir recently secured options on surrounding property. The annual meeting will be held on August 16, when a new board of directors will be chosen. At the same time a proposition to amend the articles of incorporation to permit a bonded indebtedness of \$650,000, and to re-incorporate under laws of some other State than Nebraska, will be taken up. The Mines Exploration Co. is a new concern just organized by officials of the Utah Copper Co. with a capital of \$500,000. The incorporators and officers are: Charles M. MacNeill, president; Spencer Penrose, secretary and treasurer; D. C. Jackling, general manager—all of whom are officials of the Utah Copper Co. They, with Edmund Jeussen and C. C. Hamlin of Colorado, complete the board of directors.

The new board of directors chosen at the recent annual meeting of the Consolidated Mercur Gold Mines Co. has organized with John Dern, president; Hubbard W. Reed, vice president; A. Reeves, secretary, and George H. Dern, general manager. The annual report will be issued in about three weeks.—The Sacramento Gold Mining Co., of Mercur, has shipped another lot of quick-silver amounting to 441 flasks.

Eleven Utah mines declared dividends in July amounting in all to \$177,000; the Gemini paying \$50,000; Silver King, \$50,000; Mammoth, \$20,000; Beck Tunnel Consolidated, \$25,000; Grand Central, \$15,000; Victoria, \$10,000; Bullion-Beck, \$10,000; Carisa, \$5,000; Uncle Sam Consolidated, \$5,000; Utah (Fish Springs), \$2,000; Sacramento, \$5,000.

The management of the United States Smelting, Refining & Mining Co. has placed an order for two more converter-stands, a total of five for the Bingham June

tion smelter of that corporation. The concentrator situated near the smelter, which has been running on low-grade silver-lead ore from the Old Jordan and Galena mines at Bingham, will also treat custom ore in future.

Ore shipments are again being made from the Consolidated Flagstaff mine, at Alta.—Control of the Gipsy Blair property, near Alta, has passed to the officers of the Kennebec Mining Co. The Gipsy Blair will be utilized for a tunnel-site for the Kennebec.—Shareholders of the Steamboat Mining Co. have ratified the action of the directors in the sale of the property to Jesse Knight, of Provo. The property is in the Big Cottonwood mining district.

CRIPPLE CREEK, August 6.

A car of ore was shipped July 30 from the Trachyte claim of the United Gold Mines Co. on Bull hill, to the Eilers plant at Pueblo of the American Smelting & Refining Co. A rich streak 8 in. wide is being broken by two machines at a depth of 300 ft.; the working width is about two feet. The screening from this ore gives a return of about \$70 per ton in gold.

During the month of July the Gold Dollar mine on Beacon hill shipped, on an average, one car of \$30 ore per day. The ore is obtained by the company on the eighth level and is shipped with very little sorting. Beginning August 1 the Last Dollar mine, situated on Bull hill, will be worked under lease by John Price and Jesse Waters. The lease is for two years and it is understood that considerable development work will be done to prove up this property. The Bluebird mine, owing to the absence of the owners in Nevada, has been closed down, but will resume work shortly on their return, which is expected to be some time this week.—The last three months have been very favorable for the Vindicator Gold Mining Co. on Bull hill. The average monthly profit was a little over \$27,000, which was excellent considering the amount of expense incidental to getting the newly acquired Hull City placer into shape for profitable production. The regular quarterly dividend of \$45,000, on three cents per share, has just been paid, making a total disbursement to date of \$1,470,000.—The Gold Sovereign mine shipped approximately 1,000 tons of 1½-oz. ore during July, three-quarters of it being mined by lessees and the remainder by the company.

Although the tonnage shipped from the Cripple Creek district during July was a little lower than that of June, yet the grade was sufficiently higher to make the total value about \$50,000 greater than for the previous month.—The Western Investment Co., one of the largest leasing combinations operating in the district, R. A. Miller and the Sacramento Mining Co., are being sued by Becker, Travell and McDonald, in the sum of \$10,000 for ore wrongfully extracted by the former parties on the Sacramento claim of the Stratton Estate. A lease was granted to the plaintiffs on the Sacramento claim in August of last year to run for a period of 18 months, work being started immediately. In January last, with the consent of the Sacramento Co., a contract was entered into with R. A. Miller, giving him authority to work the lease for the plaintiffs at the same time conforming to the conditions of the said lease. In consideration of this Miller agreed to pay an additional 5% royalty on all ore shipped by him, over the 20% payable to the Sacramento Co. About three months ago Miller entered into some agreement with the Western Investment Co., whereby the latter company was let into possession of said premises and has since been extracting ore of very fair grade, paying to the Sacramento Co. 20% royalty and to the plaintiffs 5%. This contract between Miller and the Western Investment Co. was made without the knowledge of the Sacramento Co. or of the plaintiffs. The lat-

ter refuse to accept the 5% royalty, or to recognize Miller's right to assign his contract to the Western Investment Co. which has no authority to mine any ore from the Sacramento property. The ore is being mined at a depth of 325 ft. and is being shipped at the rate of a car every other day; it is supposed to be a continuation of the rich orebody which is being worked in the Specimen claim, to the north.

The suit of the Creede & Cripple Creek Mining Co. against the Uinta Mining, Tunnel & Transportation Co. and the Portland Gold Mining Co., which has been in the courts for several years, has been finally settled by mutual agreement. A tunnel right of way through the Portland property was sought by the plaintiff company, which was granted by the district court of El Paso county, but this decision was reversed by the United States Court at Denver, where the case was taken by the defendants. The case was then carried to the Court of Appeals, where the right to tunnel through the Portland property was again denied the plaintiff company. The final settlement was made out of court between the three companies and the papers were filed in the district court of El Paso county on August 4. In the articles of agreement, while the tunnel is not allowed, certain concessions are made by the three companies.

It is stated on good authority that papers are shortly to be filed with the Secretary of State incorporating the Cripple Creek Drainage & Tunnel Company for the purpose of driving the deep drainage adit for unwatering the district. One million shares, of a par value of \$1 will be the capitalization, and each company interested will purchase a block of stock. The following constitute the board of directors: Frank S. Castello of the Mary McKinney, Frank G. Peck of the Portland, Sherwood Aldrich of the Elkton, S. S. Bernard of the El Paso, F. J. Campbell of the Vindicator, A. E. Carlton of the Findley, C. C. Hamlin of the Granite, and William J. Chinn and J. A. Ritter, attorneys of Colorado Springs. The two last named gentlemen will resign as soon as representatives from two other mining companies are elected.

DENVER, August 1.

The Portland Gold Mining Co. has filed suits against Stratton's Independence Co. and numerous lessees, for various amounts aggregating \$360,000. W. S. Stratton and the Portland Gold Mining Co. agreed upon a vertical boundary-line years ago, so there will be none of the expense and complexity about this suit that usually attends apex cases. It is pretty hard for anyone, and particularly for a lessee, to quit good ore because he is getting close to his neighbor's line. He probably does not know exactly where the line is, and gives himself the benefit of the doubt, to the extent of a foot or two. There seems to have been nine different cases of this kind for which the Portland Co. seeks redress. The amounts sued for are very likely greatly in excess of the gross value of the ore removed, to say nothing of its net value. The suits are brought in the U. S. district court.

Camp Harrington is the name given the new camp on the Tennessee fork of the Arkansas, above Leadville. I have previously mentioned the discovery of good bodies of ore in this range a little farther south. The Jennie June, at Camp Harrington, which has attracted considerable attention lately, has just changed hands. James Shinn, of Leadville, has been appointed superintendent and will install a hoisting plant.

The Clear Creek basin continues to lead the State in the number of new strikes. I cannot say, however, whether the discoveries are of as great importance as those of other districts. For instance, the discovery of a new orebody at Leadville, such as was made in the

Mammoth, is apt to mean more to the State than the discovery of several Clear Creek basin ore-shoots. One of the latest strikes was in the Sleepy drift of the Marshall tunnel in Equator ground at Georgetown, where 8 to 12 ft. of 400 oz. silver ore is reported. Another strike was made at Empire in the Denver City property, and another in the American Sisters mine at Georgetown. The Two American Sisters Mining, Milling, Power & Electric Co. is the official name of the company, and it is putting in considerable machinery, including a 550-h.p. hydro-electric plant. If its pocket-book is as long as its name it ought to have a fine plant, and it is generally believed that it has a good mine.—L. G. Nesmith, of Central City, has gone East to arrange for re-opening the old Kirk mine on Quartz hill. The mine has lots of uranium ore as well as some gold-milling material, but it needs a new hoist to get it out.

One of the most important developments going on this summer is the continuation of the Yak tunnel at Leadville under Big Evans gulch. Leadville is naturally a wet camp, and the discoveries in that district warrant active prospecting. The draining of the ground will greatly facilitate prospecting, and some big discoveries ought to be made.

DENVER, August 6.

Very little has been heard of Rico since the consolidation of the big mines there, a few years ago. At that time great predictions were made of the brilliant future of the camp. The work of development was placed in the hands of a clever young engineer. An attack of pneumonia carried off the engineer, development work stopped, and everything came to a standstill. Apparently the company could find no one else in whom they had confidence, so nothing was done. This year, however, the mines have started up again on the leasing system and heavy shipments of ore are being made. Underneath the very town of Rico, and extending under Newman hill, is an enormous body of zinc-lead ore. It is called the Atlantic Cable deposit and is considered one of the largest known orebodies in the State of Colorado. Needless to say, there are difficulties attending its exploration or it would be more energetically worked. The ground is wet and the average grade is low. The rise in the price of zinc makes possible the mining and shipment of the richer parts of this vast lode, and this summer the production is so heavy that the railroad finds itself short of cars on the Rico division. Most of the tonnage is hoisted through the Atlantic Cable shaft. Rico also yields a considerable tonnage of the typical high-grade silver ore, such as made the Enterprise and Rico Aspen famous in the early days. The camp undoubtedly needs a concentrating mill. With the modern improved methods of treating zinc ore there would be no trouble in making a clean separation of the zinc and lead, and that is all that is needed to make profitable the mining of thousands of tons of ore in Rico which are already developed. It is understood that A. B. Roeder, the promoter and manager of the United Rico Mines Co., is now working on plans for a mill of large capacity.

The old Neigold property, above Silverton, has long been one of the famous mines of the San Juan. Old man Neigold firmly believed that he had millions of tons of high-grade ore actually developed. It was a bad case of self-deception. That he had a most remarkable property every one who saw it agreed, but the old man's conception of its value was far beyond conservative consideration. How the Old Hundred Mining Co. managed to get hold of the property I do not know, but it did, and this summer its new 40-stamp mill is contributing to the stream of white and yellow metal which western energy and brains coax and crush out of the heart of the Rocky

Mountains. Robert W. Davis, Jr., the manager, is an experienced millman, and he has undoubtedly put up a fine mill.

The Clear Creek basin demands notice again this week. It is remarkable what a lot of good strikes they are making up there this summer and what a lot is going on in a quiet unpretentious way. It is true that the chambers of commerce at each of the three towns, Idaho Springs, Georgetown and Central City, are making a special effort to advertise the country this summer, but this is rather the outcome of the prosperity that has come to them, than the cause of it. At Georgetown the Lima Con. Mining Co. finds itself in need of a new mill and a couple of new tramways. They are operating on Republican mountain. The mill, I understand, is to be erected below the portal of what is called the Moline cross-cut. The officers of this company are all local people of recognized standing, and the chances are that when such people find something that is good enough to equip with a mill and too good to sell to an outside company, it is very good indeed. William C. Hood is the manager and Frank Maxwell, the well-known surveyor and mining engineer, is president. The best ore ever found in the Newhouse tunnel was struck in the Saratoga lateral last Monday. This strike is fully as important as the famous Gem discovery of 18 months ago, but people have become so used to hearing that the extensions of famous ore-shoots have been cut in deep cross-cut tunnels that little interest is aroused when another is stated to have been found. In this case it is the extension in depth of the famous Saratoga shoot that has been cut. The vein is a foot wide and assays \$171.60 per ton.

The Big Five has succeeded in getting the \$100,000 that it was planned to raise before beginning work again on its long adit. This money assures the pushing of the 'tunnel' into the country of big producers, at the head of Virginia gulch, before the work ceases. It reminds me that Ben Owens and associates have taken up the famous old Crown Point and Virginia mines at the head of Virginia gulch, and are going to operate them actively. The Newhouse tunnel has partially drained the ground, so that operating expenses will be much less than at the time when they were shut down.

The Argentine Central was formally opened last week. This little railroad runs from Silver Plume past the Wilcox mining properties to the summit of McClelland mountain, 14,000 ft. above sea-level. I believe it is the highest railroad in the world except the Peruvian Central which crosses the Andes at over 15,000 feet.

TORONTO, August 3.

Thomas W. Gibson, Deputy Minister of Mines, has received further reports from Prof. W. G. Miller, in charge of the exploration party prospecting the Gillies timber limit near Cobalt, from which it appears that recent discoveries of ore are richer than at first imagined. So far 65 ft. of the vein has been uncovered. Prof. Miller's samples were sent to the Provincial assay-office. One carried 1,936 oz.; the other 2,957 oz. silver per ton.

Among American capitalists visiting Cobalt recently was a party from Pittsburg and other Pennsylvania cities, including A. P. Macauley, Richard McCormack, P. J. McCormack, Mayor Black of McKeesport, Bernard Volk and Squire Richards. After a careful inspection of conditions they secured 44% of the stock of the Eureka Silver Mining Co., which owns a producing mine with the moderate capitalization of \$100,000. They intend to operate it on a more extensive scale. They wished to secure a controlling interest, but the Toronto stockholders declined to sell it. The party looked into other propositions and secured samples of ore for assay, so that other investments are expected to result.

Reports concerning the finding of diamonds in New Ontario continue to be extensively circulated. The officials of the Provincial Department of Mines do not attach any significance to these stories, which crop up periodically every few months. Geological experts do not regard it as at all probable that diamonds will be found in place in this Province, though it is possible that occasional gems may be picked up in the glacial drift, as has been the case in the adjoining northwestern States.

J. Lauzon has returned to Sudbury, Ont., from a prospecting trip to the new Lake Opastica goldfields. He was very favorably impressed with the region, stating that gold is plentiful and the deposits easily worked. He secured a location, samples from which assayed \$21 per ton, and will proceed to develop it. The principal drawback is the Quebec mining law, which retards enterprise by permitting individuals to monopolize large areas. Some holdings extend over 150 square miles, from which all other prospectors can be excluded.

The facts respecting the deal under which the Right of Way Mining Co., of Ottawa, secured the mining concessions on the Temiskaming & Northern Ontario Railway, have created so much adverse comment that the Provincial Government will probably cancel the agreement and call for fresh tenders. It appears that the terms on which the concession was granted by the Temiskaming & Northern Ontario Railway Commission were considerably varied from those specified in the call for tenders. The latter provided for a royalty on the output, at a rate varying from 10 to 50% of the value according to the grade of the ore. This the company refused to accede to, so the terms were varied, making the royalty a flat rate of 25% of the value of all ore mined. This disclosure, coupled with the fact that the principal promoter of the company is the son of Dennis Murphy, a member of the Commission, aroused public opinion so strongly that the transaction will probably go no further. As all official acts of the Commission must be ratified by the Government, the final step has not yet been taken. The press is calling for the dismissal of Mr. Murphy.

Iron ore has been discovered by W. A. Cockburn, of Sturgeon Falls, Ont., in Kirkpatrick township, two miles south of Verner station, on the Canadian Pacific. The vein is about 25 ft. wide.

The Canadian Pacific Railway is making tests on an extensive scale at Medicine Hat, Alberta, to determine the presence of oil underlying the natural gas. Nine carloads of modern machinery have arrived, comprising a cable-rigged drilling outfit and drill-pipes sufficient to reach a depth of 3,500 ft. Coal has been discovered within a few miles of Battleford, between the Saskatchewan and Battleford rivers. The prospector refuses to divulge the exact whereabouts of the deposit, until he succeeds in getting capital interested with a view to its development.

TORONTO, August 5.

The Provincial Government of Ontario yesterday definitely refused to sanction the mining concession made by the Temiskaming & Northern Ontario Railroad Commission to the Right of Way Mining Co. New tenders will be called for. The company, which claims to have acted in good faith, will claim reimbursement of expenses incurred and threaten a lawsuit unless compensated. This matter has aroused much interest.

A party of Toledo, Ohio, capitalists is investigating the silver mines in the Port Arthur district with a view to re-opening them, should investigation prove satisfactory. These mines include the East End Silver Mountain, West End Silver Mountain, Badger, Porcupine, and Keystone properties, which in the early days were good producing mines, but closed down when the depression in

the price of silver rendered it impossible to work them profitably. There is no doubt that they still contain rich veins of ore.

BISBEE, August 5.

At the Copper Queen smelter there was a little falling off in the output last month, on account of the two days' shut-down at the beginning of the month, and owing to the caving of the Holbrook shaft, which decreased ore shipments considerably. The output for the month of July was about 7,750,000 lb. copper. The precipitating plant at Bisbee has proved a success, saving about 80% of the copper contained in the water. The new compressor at the Czar shaft has been completed and is now in use. The management of the Copper Queen Co. is working on a plan to inaugurate a new system of hauling ore from the lower levels. The plan is not yet completed, but the general idea is to hoist all the ore through the Gardiner and Spray shafts by means of electric power. A large plant will be built on Sacramento hill to furnish the necessary power. The Holbrook shaft, that is the new one, will be used only for hoisting men and timbers; it is to be put down at a distance of about 150 ft. from the old one.

At the Calumet & Arizona smelter, the July production was 3,854,000 lb. copper. Everything is about the same as usual at the smelter and at the mines.—At the Lake Superior & Pittsburg shaft the foundation for the new hoist has been completed. The work of constructing the new engine-house has been started, and the boilers will be put in position this week. As soon as the engine-house is completed, the new hoist will be erected. On Wednesday a body of rich sulphide ore was opened up on the 1,000-ft. level of the Calumet & Pittsburg. The work is still in ore. Sinking continues at the Junction. At the Hoatson, the pumping plant being installed on the 1150-ft. level will be completed this week, and then sinking will be resumed.

At the Shattuck & Arizona preparations for the shipment of ore are being pushed forward. On the 600-ft. level the work is in a body of oxide and carbonate ore which is showing up satisfactorily. On the 700 two high-grade sulphide orebodies are being opened up. On the 800 the drift is in low-grade sulphide. The two raises from the 800 to the 700-ft. level are progressing rapidly. The ore-bins have been completed. They have a capacity of 1,000 tons. The cables for the tramway are being strung, and will be in position this week. The new steel head-frame was erected this week and will be put into commission on Thursday. There are two new boilers on the ground, and as soon as the preparations for shipping have been completed, they will be set up. The railroad spur will be ready for use August 12. A new building will be erected to contain offices for the superintendent, the chief engineer, the chief clerk, and the assay department. The water-supply has been falling off, but on Friday a flow of 150 gal. per min. was struck on the 800-ft. level. Striking water has been an invariable forerunner of an orebody in the Shattuck.

At the Denn-Arizona, they are still sinking the shaft, and are down about 1,060 ft. A body of iron ore was encountered in the shaft about ten days ago, and has not been penetrated yet. The character of it changed a little on Friday, when some vein-matter and soft material were opened up. On the 1,000-ft. level, the iron orebody encountered about three weeks ago was penetrated, and a body of manganese exposed. It will be but a very short time before an orebody is opened up, according to the best advice.

The main interest here this week has been centered in the transfer of the Cananea-Duluth, American, and Bryan properties at Cananea, by the Cole-Greene interests. The

deal has not been entirely closed as yet, the apportionment of stock remaining to be fixed. The new company will be called the Cananea-Central, with a capitalization of \$10,000,000, or 1,000,000 shares of \$10 each. The stock market here has been very active this week.

CANANEA, Mexico, August 6.

A company which has been mining a rich silver mine in the Ajos mountains for the past three years and which has escaped notice, owing to the policy of the management, is the Alsace Mining Co. This company is composed of a number of Frenchmen who are putting their own money into the property and are working it on shares. The result has been that they are all getting rich, for the mine has turned out to be a property of great value. No stock has been issued. The ore is said to assay about 450 oz. silver, 2.5 oz. gold and from 4 to 15% copper; it is packed to the railroad and shipped to El Paso.

The development of the Llanos de Oro placers, by the company of which Epes Randolph and associates are the owners, has proved several facts not hitherto suspected concerning these deposits. It has been demonstrated that there are two beds, one above the other, with a false bedrock between, at a depth of from 15 to 50 ft. In the Llanos de Oro mine at 105 ft. the lower bed has been found; the gold occurs in the form of fine shot and nuggets, mixed with large pieces of country rock. The conglomerate mass shows that it has been subjected to the action of water only slightly. This lower bed of ore has been opened up extensively, and it is said that there is about \$8,000,000 worth of it in sight. The 100-stamp mill on the property is only using 50 heads at present, but it is expected that the full battery will be dropping before September.—The Boston Copper Co. has let a contract for the sinking of five diamond-drill holes on its property in the Ajos mountains. These holes are to be sunk 300 ft. and it is expected that the orebodies will be tested in this manner at a much less cost than by using ordinary prospecting methods.—The Brooks Con. Copper Co. will reach ore in 25 ft. in their main shaft on their property in the Cerro Tordillo district, about 30 miles east of Cananea. At present small stringers of high-grade ore have been found and the water in the shaft is tainted strongly with copper.—J. P. Chase, in the same district, has run into ore which assays 15% copper, 40 to 60 oz. silver and \$3 gold. The vein is seven feet wide and gives every indication of increasing in size and value.—B. F. Pinson has denounced 160 acres in the Ajos mountains, 70 miles east of Cananea. Assays from the surface give from 3 to 20% copper, 20 to 35 oz. silver and about \$4 gold.

The developments for the past week in the mines of the Cananea Con. Copper Co. are as follows: At Cobre Grande mine No. 2 a cage, hoist, and 80-h.p. boiler have been installed. At the Henrietta mine an air-shaft has been started to connect with the main adit at a depth of 87 ft. A gravity tram was put into operation at the Puertocito mine and is being used to quarry the face of the hill, which consists of low-grade ore. This ore is being shipped to the smelter as fast as it is taken out, as it is the best smelting ore in all the mines. A No. 7 Cameron sinking pump has been placed in the main shaft of this mine, and the new air-compressor is working and giving great satisfaction. It is of 13-drill power. The shaft at Veta 8 is being sunk rapidly, and has reached the 110-ft. level. At 260 ft. a drift will be run to meet the shaft at Veta 5. Thirty feet of ore has been cut in Veta 8 and indications are that more will be found before starting the drift.

The Cananea Eastern Mining Co. has 70 ft. more to run on the adit which is being driven to cut the lode, at a depth of 200 feet.

Mining Summary.

ALASKA.

Alaska gold shipments for 1906 now reach \$10,562,870—nearly as much as they did at the close of last season. A total of 22 shipments has been made from the country. Of these half came from the vessels sailing to Nome and St. Michael direct, and gold aggregating \$4,618,000 was brought down by them. From the southeastern section, 11 shipments were received, totaling \$5,944,870. A total of 18 vessels has made the round trip to either Nome or St. Michael; only 664 have returned up to this time direct from those ports.

Reports from Rock creek, near Glacier creek, say that the work done there last winter is beginning to bear fruit. The Nome Quartz Mining Co. has been working on the Gold Reef quartz claim there since October. Work was begun on a shaft, which was put down 70 ft., and a cross-cut run to the vein. The ore contains pyrite, mispickel, and gold.—The Wild Goose Co. has been operating on Dry creek for some time, and has succeeded in finding the old beach line. There is said to be good pay on the bedrock. The company is moving a hoist and outfit on to the new strike from the Honey claim.—Nels Christenson and Adams & Ashley are sinking holes in the vicinity of the new strike.—L. L. Bales says the story of recent remarkable gold discoveries on the Alaska peninsula is exaggerated. He was recently at Sand point and states that the deposits found there, and at St. John, are of the kind that can be found anywhere on the peninsula.

ARIZONA.

COCHISE COUNTY.

The shaft on the Tombstone Consolidated Mines Co.'s Silver Thread property, being drained by the pumps at the Grand Central shaft, was sunk to water level 600 ft. below the surface, where a new high-grade orebody was encountered. A drift was started at water level which passed through the upper portion of a new shoot of ore. The shaft where the ore was encountered was sunk from water level through solid ore to a depth of 100 ft., where a drift has been run for 80 ft., and is still in ore.

GRAHAM COUNTY.

(Special Correspondence).—On Friday evening, July 21, John Chisholm, Jose Alarcon and Leandro Vasquez lost their lives by a cave in the Coronado mine, of the Arizona Copper Co. at Metcalf. After the accident the entombed miners communicated with the other miners, but before they could be reached they were dead.—The Stephens claims, on American mountain, are reported to be showing up favorably. George Stephens, who is operating the Stephens mine under a lease, reports that the vein of rich ore recently discovered is four feet wide and will average 26% copper. He is also developing a body of sulphides in another part of the mine which assays 8% copper. The management of the Gold Belt Development & Reduction Co. reports the discovery of manganese ore which assays 25% copper. A shipment will be made to the Detroit Copper Co.'s smelter at this place.—The June production of the Shannon Copper Co. was 738,000 lb., as compared to the May production of 1,230,000 lb., due to the fire at the top of the incline, which necessitated shutting down the works for more than two weeks. Normal production was resumed June 27.

The development at the Shannon mines is entirely in new orebodies, and the ore reserves are now larger than ever before.—Nathan F. Leopold, of Chicago, who is interested with the Phelps-Dodge people in the Burro Mountain Copper Co., spent a few days in camp as a guest of C. E. Mills, superintendent of the Detroit Copper Co.—The electric power-line has been completed to the three claims of the Detroit Copper Co., six miles from town, in the Copper Mountain district, and the installing of machinery is finished. This company is putting in a 75-h.p. motor at the Santa Rosa, which will operate blowers and other machinery. The adit at this claim is in over 400 ft. At the Espe-

ranza mine, which has heretofore been operated by a horse-whim, a 40-h.p. motor is being installed. The shaft here is down 215 ft. At the North Dakota property a 40-h.p. hoist is also being put in, the shaft being down 400 ft. The line has already been surveyed, and the company will soon extend its tunnel now running through Copper mountain to the above claims, and it is reported that in a short time this line will be extended to Metcalf, when the Detroit Copper Co. can make a bid for custom ores of that district.—Charles T. Roberts, superintendent of the Omega mine, controlled by the Zackendorff interests, reports that on the 800-ft. level the biggest strike in the history of the mine has been made.—Concentrator No. 6, recently completed by the Arizona Copper Co., is now running two eight-hour shifts, the mill being shut down the other eight hours so that carpenters can finish the wood work. Large settling-tanks for restraining and drying the tailing will be completed in four weeks. It is the intention to use the tailing to fill underground workings, thus settling the debris problem.

The Longfellow gravity-incline, owned by the Arizona Copper Co., has been extended 200 ft. at the upper end to the level of the Humboldt and Clay mines and the new adit workings, connecting with the electric road now running to all these points.—T. H. Scott, superintendent of the Scott-Allen gold claims two miles below Morenci, will resume work at the mine and will ship ore to the El Paso smelters. Morenci, August 4.

MARICOPA COUNTY.

(Special Correspondence).—The Arizona Development Co. is arranging to begin work on its property situated in Frog Tank district, 20 miles from here. Mr. Hamilton, who is the principal promoter and president of the venture, is negotiating for the purchase of a Keystone drilling machine which will be taken to the company's claims near the junction of Agua Fria river and Castle creek where several holes will be sunk to determine the character of the ore and what machinery is necessary and what development work must be done.—James C. Dobbins has placed on file location notices of 52 placer claims for the Arizona Development Co. The locators number about 40 people, the greater number of whom are residents of this city and county. The claims lie along the banks of the Agua Fria and Castle creek.—The Arizona Placer Mining Co. will probably also buy a Keystone driller. J. C. Hall is now in Los Angeles for this purpose.—The Arizona Placer Mining Co.'s property is situated above Wickenburg, on the Hassayampa. Below Wickenburg on the same river, the Hassayampa Placer Mining Co. had a Keystone machine in operation some time ago. The results were stated to be satisfactory.

Phoenix, July 28.

(Special Correspondence).—J. R. Chaption has had men during the past four months developing the Copper Monarch group, owned by W. J. Bryant, at Los Angeles. It is situated in the Eagle Tail mountains, 80 miles west of Phoenix, and was formerly known as the Volcanic. Some 12 years ago \$150,000 was spent on the property, when several shafts were sunk, but none of them on a vein. Last spring Mr. Chaption began an adit which is now in 175 ft. At 130 ft. a 20-ft. vein was crossed, carrying low-grade copper ore with some silver and gold. On the hanging wall of the vein, in the adit, there was a small rich streak on which a drift was run 30 ft. and it has widened to two feet. Several tons of shipping ore have been taken from this drift. The continuation of the main adit will cut three more veins of good width. One vein discovered on July 7 is from 4½ to 6 ft. wide. The ore, at a depth of five feet, shows gray-copper rich in silver. Two shipments of ore have been made since May with good results.—Another gold and copper property, owned by a Mr. Eaton, four miles north of the Chaption property, looks promising. Mr. Eaton will soon begin shipping ore by way of Salome, 25 miles distant.—There is also the Venture Mining Co.'s property situated seven miles southeast of the Monarch. This mine contains gold and copper, and a mill is to be erected. Water has been developed by this company and also by others who have good claims in the district.

Phoenix, August 4.

CALIFORNIA.

ALAMEDA COUNTY.

The American Magnesite Co., at Red Mountain, is operating large mines of magnesite which is being delivered at Livermore. Four traction trains are on the road regularly, and make the round trip from Livermore to Red Mountain every 20 days. It is the intention to mine 200 tons per day. These engines handle 140 tons of ore on each trip. Work is now being prosecuted on the Alameda claim, where there is a body of ore 85 ft. wide. The ore is quarried not far from the summit of Red Mountain, carried through a chute to adit No. 1, trammed in cars to the upper bunker, and carried by aerial tramway to the lower bunkers, where it is kept to await the arrival of the traction-trains. C. H. Spinks is superintendent.

AMADOR COUNTY.

The Mitchell mine near Pine Grove is again running, 14 men being employed. Ten stamps of the mill are in operation. The climax mine is also running on a small scale. Only four or five men are employed. T. B. Aitken is superintendent.—The Lucas mine, situated on the Calaveras side of the Mokelumne river, is being operated by a company, which also runs the Tripp mill of 10 stamps on the Amador side. An eight-foot vein has been exposed, carrying free gold and a good percentage of sulphurets.

ELDORADO COUNTY.

Crane & Mooney are working the old Mulkey claim at Cedar Grove, where they have opened up some good gravel.—Maylone & Papinau are ready to turn the water on their claim at Cedar Creek. They have put in a big derrick for moving the rock.—The Phelps mine is running full blast night and day. The adit is in 500 ft. and will tap the channel in three months. Some of the mines around Indian Diggings are working. The company that is opening up the old Hickey claim is installing a big hydraulic plant, and will put in a long string of flume.

INYO COUNTY.

A new excitement is reported in the vicinity of Summit. Four miles from the camp the mineral belt is a mile wide, broad parallel lodes outcropping in many places. The ore is principally sugar quartz, considered worthless until two weeks ago, when samples assayed gave such returns that locating began at a lively rate. It is said that the surface horns at almost any spot. Nichols, the discoverer, began work on a 2½ ft. vein, showing \$3 ore on top; at 10 ft. deep he is getting \$20 assays. Nicholasville is a townsite laid out by Nichols, Unthank and Granger. It is on the railroad at the foot of the mountain, two miles from Shanghai and five from Buena Vista. The owners are sinking a well. Steady work is going on in the older mines around Buena Vista. Twelve men are employed on the Brownie, and the Buena Vista, Tip Top and others are keeping many more busy.

MONO COUNTY.

The new machinery for the Southern Belle mine, at Bodie, is expected daily.—The Bullion shaft is now down 255 feet.

NEVADA COUNTY.

(Special Correspondence).—At the Eclipse mine, Gold Flat, owned by Simmons Bros. and bonded to Tonopah people, they have struck ore showing gold freely, in the drift on the 220-ft. level. This is a continuation of the rich ore-shoot which produced \$6,200 from 50 tons of ore. They are crushing the ore in the 10-stamp Phoenix mill of the adjoining property.

Gold Flat, July 30.

Joseph Weissbein, manager of the Gold Flat mine, near Grass Valley, reports that it took one week to lower the water in the 350-ft. incline and drain the drifts and stopes. Everything was found to be in good condition and sinking will be commenced immediately, as it is intended to drive ahead 1,000 ft. and thoroughly develop the Gold Flat.

Five claims in Deadman's Flat have been sold to the Gold Mound Mining Co. of Spokane, Wash. The claims were owned by W. George, J. M. Othet, A. B. Adams, Arthur Cook, George Trotter, H. Reber, and others. They include

the Boyle & Roach, Gold Cup, '1903,' West Virginia and Lucky Boy, and are situated near the Baltic.

SHASTA COUNTY.

Ore is being hauled from the George Stanton mine, near French Gulch, to the railroad, for shipment to the Selby smelter.

SISKIYOU COUNTY.

W. H. Young, general manager of the Gold Ball mine, owned by the California Consolidated Mining Co., says that the vein for which they have been running in the lower level of the mine was recently struck, and sinking is in progress. It is five feet wide and will mill \$20 per ton. The company will make arrangements to handle the mine on an extensive scale, and will install an electric-power plant near Sawyer's Bar and will add a lot of new machinery, including an air compressor, machine-drills and hoisting works.—N. E. Graves, superintendent of the Sheba mine near Fort Jones, says he has recently struck the rich shoot of ore in the lower level of the mine.

TUOLUMNE COUNTY.

(Special Correspondence).—An adit that will cut the vein at a depth of 450 ft. is being driven at the Bourbon mine, in the Jupiter district.—At the Saratoga Mining & Development Co.'s mine, at Mountain Brow, near Columbia, an incline shaft that will connect with the long adit has been commenced. A night shift has been added to the force.—The Dondero gravel mine, near Yankee Hill, and the adjoining property owned by Antone Podesto, have been bonded to Hildreth & Dennison.—The water has been lowered below the 400-ft. level in the Davidson shaft of the Soulsby mine, and a 10-in. pump is being installed at that level. Sinking continues in the Pennsylvania shaft, now 700 ft. deep.

Tuolumne, August 6.

William Sharwood and wife have entered into an agreement with the Bagdad-Chase Gold Mining Co. to sell the Soulsby mine and adjacent mining property, with all improvements thereon, for \$200,000, to be paid in installments as follows: \$50,000 in 12 months, \$50,000 in 18 months, and \$100,000 in 24 months, from January 10, 1906.—It is understood that work is to be resumed in several of the old mining claims in this county—not in the well-known mines, but prospects that were dug and abandoned in the early '50s, when quartz mining was in its infancy.

COLORADO.

CUSTER COUNTY.

At 68 ft. depth in the Bismuth, the lessees, Stroehlke & Preston, have ore in the drift after driving 30 ft. from the shaft. The entire drift is in ore running 16 oz. silver. Through the centre of the vein runs a three-inch streak of ore resembling gray copper and showing horn-silver. An average sample from this streak assayed 1,818 oz. silver, or about \$1,000 per ton.

GILPIN COUNTY.

W. F. Hogan, the new manager of the Gunnell property west of Nevadaville, says that a temporary hoist will be installed on the pump-shaft to clean it out and to re-timber that shaft, which has been idle since the fire destroyed the surface plant in March, 1904. When the work is completed the company will arrange for a plant capable of hoisting from a depth of 2,000 ft. If possible the pumps may be fixed up and used, but if they are found to be in bad condition the new company will install a new equipment. The company will not interfere with the present leasing system on the Grand Army and West Whiting mines, which are doing well, but will encourage leasing. Improvements will be made in the mills at Black Hawk.—In order to demonstrate the comparative results in marketing the medium-grade ores from the Old Town mine, George K. Kimball, the manager, made two tests. One lot of 120 tons was sampled at the ore buyers, for which, under the smelting schedule, he would have received \$23 per ton net. The lot of ore was then treated at the Jackson mill, making 35 tons of concentrate for which he received, deducting mill charges on the ore, freight, hauling and smelter treatment, \$89 per ton. The mill saved 92% of the gold, 72% of the silver and 58.2%

of the copper content, and Mr. Kimball received close to \$2.50 per ton more by treating his ore by concentration than he would have received by selling direct to the sampling works.—Another lot of 105 tons was treated at the Alpine mill where a saving of 90% of the gold, 90.7% of the silver and 50% of the copper was made. The sampling works offered \$2,144 for the shipment, but by concentration to 29.4 tons, deducting all expenses Mr. Kimball received \$2,338, or a profit of \$194 by milling the ore instead of selling direct to the smelters.

OURAY COUNTY.

L. A. Thompson, general manager, and V. W. Mather, foreman, of the Mickey Breen mine of the Tempest Apex Co., who disappeared several days ago, were found dead August 3 under a mass of debris in a small tunnel half a mile from the Breen mine. They evidently sought refuge in the tunnel from a cloudburst, and were overwhelmed by the rocks and dirt that washed into the opening from the mountainside.

SUMMIT COUNTY.

(Special Correspondence).—Owners of the Washington mine have decided to put in additional concentrating and separating machinery to handle the zinc content of their ore.—The Little Sallie Barber mine is now working on ore at the 100-ft. level and the product, which assays \$2 gold, \$13 in silver and a little lead, is shipped.—The Senator mine on the Upper Blue is opening up well. A number of stockholders recently visited the mine and adjoining properties and are well pleased with the progress made.—The Bullion King on Gibson hill is being developed by Foote & Hight under lease and has made a record production of high-grade zinc ore. King & Hammel, sub-lessees, have opened an 18-in. vein of lead carbonate on the surface.—In the Old Union mine it is expected that connection will soon be made between the main adit and old surface workings, which will afford cheaper working activities and better ventilation.—The mill on the lucky mine is working on the low-grade ore, making good grade of concentrate. A new strike of high-grade shipping ore has just been made.—At Kokomo, activity is apparent everywhere, and the results of milling tests on the complex zinc ores having been favorable, the old zinc properties are fast being revived.—At the Wildfey mine a furnace is being erected to prepare the more complete zinc, lead, and iron ore for treatment by electro-magnetic separators.—On the Felicia Grace an important strike has been made. This property is being operated by Leadville men. The present owners took possession early the past spring and sunk a 180-ft. shaft. At 110 ft. a drift was run to the old workings and in doing this a new orebody was cut, samples of which assay \$5 gold, 80 oz. silver, and 30 to 40% lead. The upper contact also contains considerable pay-ore and this mine will soon be among the shippers.

Breckenridge, August 4.

TELLER COUNTY.

Experiments are now being made in the treatment of the low-grade ore, both sulphide and oxidized, on Gold hill. The Lexington Co. has sent a trial shipment of \$10 and \$12 ore to the Craig cyanide mill at Anaconda, the milling company having fitted up special machinery for this purpose. There is a great deal of low-grade ore in the Clara D., and on Ironclad and Globe hills there is much low-grade ore of similar kind.—Bull hill also has much oxidized ore, and the mill being built by the Isabella Co. will have several bodies to work on. There is a shoot running through the Isabella to the Victor, which runs \$10 per ton. In the past, attention has been given principally to the high-grade ore, but conditions now justify the treating of that of lower grade.

The Lonaconing mine on Beacon hill, now under lease to A. E. & L. G. Carlton, is one of the best shippers in that part of the camp. Its output has steadily increased from the time the operations of the present lessees began. The ore is obtained at a depth of 300 ft. It is likely that the Lonaconing will be able to maintain its present rate of production for several months.

Some unfavorable assays are reported by Cripple Creek men who went to the Spaulding district and staked claims

at Ilse several weeks ago. The rock looks like ore, but in most cases is too low grade to make even cyaniding ore. W. O. Burnside and W. L. Smith have the best showing to date, and have assays averaging \$5.60 across a 14-ft. vein in a 50-ft. shaft on the Custer claim. On four other claims of these prospectors, the following figures were obtained: Hoza \$8, Franklin \$1.20, B. S. \$0.80, and the School Section \$1.20. The four last assays were obtained at surface.

There has been so much rain in the Cripple Creek district during the last 30 days that practically every shallow shaft in the camp has been affected. The water is deluging many leases and prospect work has been nearly at a standstill. There are several mines where the shafts are down to 200 and 300 ft. that have been troubled with water.—The War Eagles, on Bull hill, last week got out all the water in the shaft. Three shifts of men have been continually employed in hoisting water.

IDAHO.

BLAINE COUNTY.

In Wood River mining district, the Flynn Con. Mines Co., organized by Butte men, has an orebody outcropping 318 ft. thick at the base and 92 ft. high. In another place 18 ft. of ore has been developed on both sides of a gulch. The property is 18 miles northwest of Ketchum, and consists of 14 claims adjoining the Dollarhide mine.

LEMHI COUNTY.

G. G. Shallabarger and G. C. Wegele, of Horton, Kas., have been inspecting the works of the Gold Ridge Mining Co., at Leesburg. The adit has been run in ore 200 ft. and will be driven 2,500 ft. It is the intention to install a mill in a short time.

SHOSHONE COUNTY.

At last reports the orebody recently cut in the New Hope mine, on Two Mile Creek, three miles from Osburn, has widened to 15 ft. Most of the ore is galena, and there is said to be considerable shipping rock in sight.—The Bunker Hill & Sullivan Mining Co. has given an eight-hour day to its employees. No change is made in the wages paid in any department.—A report from Mullan states that on August 3, 16 shaftmen employed at the Morning mine, owned by the Federal Co., struck for a six-hour day, or for \$5 per day for an eight-hour shift. The men have been working eight hours for \$4, but claim that as other miners have been given a reduction of two hours per day they should receive the same. The miners in the upper workings of the Stanley Consolidated Mining & Milling Co., which is developing a group of claims on Gorge gulch above Burke, quit and demanded their pay. The company refused the eight-hour day and paid them off. In the lower workings of the property the eight-hour shift has been in vogue for some time.

The management of the Eureka Mining Co., developing a group of claims up Nine Mile creek, near Wallace, is preparing to construct a flume and a compressor plant in the near future. Grading is under way. The flume is to be 2 by 3 ft. and 2,000 ft. long. Angus Marshall is manager.

MONTANA.

GRANITE COUNTY.

The Goodhope Mining Co. at Phillipsburg, on August 3, shipped four bars of silver bullion from the Hope mill. They were valued at \$5,300.—Although the Granite Mountain Bi-metallic property is idle, lessees and prospectors are active about Phillipsburg. Ore shipments average 50 to 75 tons per week. This tonnage is distributed among a large number of lessees, each of whom is making more than wages. When the Granite Bi-metallic company was operating nearly all the men in the district were employed by it, but since the suspension these men have scattered in the hills, secured leases on properties that were idle before, and are now opening them up in good shape.

MEAGHER COUNTY.

Material for the new cyanide plant at the Gold Reef mines, on South Boulder, has arrived at Flint, and is being moved to the mine. The plant will have a capacity of 20 tons daily and is to treat tailing as well as ore. The gold in this ore is not entirely free and could not be treated in the mill designed to handle free ore only. Experiments showed that it was amenable to the cyanide process. J. H. Price

is superintendent.—The Terry cyanide plant, built this summer to treat tailing from the Royal, in the same district, is working successfully.

NEVADA.

NYE COUNTY.

The recent labor disputes at Tonopah and Goldfield resulted in the following arrangement: An eight-hour day for every workman and a general day wage scale of \$4 and \$4.50, with \$5 and \$5.50 for the more expert classes of labor.

(Special Correspondence).—It is reported that the Sedan claim, in which high-grade ore was found last week, has been sold for \$45,000 and a large block of shares of stock in a company to be incorporated. W. P. Jenney consummated the deal with B. L. Smith, one of the owners of the claim. Mr. Garrett, another of the owners, has been retained as superintendent. A double-compartment shaft has been started, in which the rich vein was again encountered. The 12-ft. vein cut last week in the adit of the Manhattan-Nevada Gold Mines Co., at Central, is being developed. The adit is now in 125 ft., the face being gold-bearing lime-spar (calcite).—In the drift from the shaft on Lease No. 3 of the Manhattan Cowboy Mining Co., a four-foot vein has been encountered, assaying \$25 per ton gold across the vein. This orebody is believed to be a continuation of the Union No. 9 vein, of the Manhattan Dexter Mining Co.—Free gold is being found in the adit on the Manhattan Mammoth Mining Co. at East Manhattan. The entire face is in ore that pans in free gold. A new vein has been discovered below the adit on the Mammoth and many specimens have been found.—The Consolidated Manhattan Mining Co. is watching developments on this vein, as it is close to its line. A survey indicates that the vein will be cut in the Consolidated adit within 25 ft. It is 150 ft. long and the face is in milling ore.—Good ore has been encountered on the Manhattan Jumbo mine, northeast of East Manhattan. Elwood Maden, one of the owners, while prospecting, sank a shaft through the cap, and in a few feet found a good-sized vein which pans gold.—Several pieces of rich gold rock were brought into town yesterday by a prospector, who claimed to have found them on his property near Millett, 40 miles north of Manhattan. Several parties left for the scene of the alleged strike this morning. The camp of Millett came into existence last spring, and is near the site of several old silver mines which have been idle for years. Water and fuel are abundant.

Manhattan, August 4.

LYON COUNTY.

(Special Correspondence).—Ramsey, a new town, with a population of 200, is at the head of Morgan canyon on the north slope of Alamo mountain at an elevation of 5,350 ft. The camp is reached by stage from Churchill, on the Nevada & California railway, 15 miles by good road.—Stage fare one way is \$5. An automobile is run irregularly from Dayton, a distance of 25 miles. The camp dates from February, 1906, when the Ramsey brothers staked 150 claims. During April, 300 men covered the district with locations, though even up to the present there appears to have been no rich rock found. The site of the camp was shifted to its present place a mile north of the first Ramsey, owing to the discoveries made on May 24 by Mr. Clark, on the Gem claim. Clark made the best find to date on ground left vacant. This is called the Lucky Boy and is not over 750 ft. long. Although there are mountains of considerable height within two miles of the camp, the topography in the immediate vicinity is one of low relief. Several east-west gulches, from 200 to 300 yd. apart and separated by ridges not more than 75 ft. high, cut a north-south range of hills, the slope being toward the east. Paralleling these gulches is a system of veins with northerly dip. The richest vein has a northeast-southwest strike with numerous crossing veins. The country rock is eruptive and normally hard, but soft and highly colored near the lodes; it is rhyolite or andesite. Water is hauled into camp from some shallow wells and a spring, a mile from camp. The deepest development is a 40-ft. shaft on the Lucky Boy claim. Trenching to find the walls has been done on this claim. On no other claim did I see more than the perfunctory open-cut or shallow

shaft. There are now 80 tents and 3 wooden buildings in town; the mercantile community comprising 3 stores, 2 restaurants, 8 saloons, 1 blacksmith shop, 1 assay office, 1 feed-yard, 1 recorder's office, 1 town-site office, and 2 lodging-houses in contemplation. Every man in camp is an optimist, and many are showing their faith by replacing tents with frame structures as fast as lumber arrives. With plenty of active prospectors on the ground, numerous veins, sufficient water, good roads, and some good ore, I believe that the elements of a permanent camp are in sight.

Ramsey, August 4.

STOREY COUNTY.

A 15-stamp mill is being built on the Comstock Lode at Gold Hill, by Utah people.

NEW MEXICO.

LINCOLN COUNTY.

Vandervoort & Wingfield have a lease on the Little Nell.—Low & Jackson, lessees on the South Homestake, are taking out ore which is being crushed in the South mill.—McIvers & Crary are getting a fair grade of copper-gold ore on their White Oaks group on the west side of the mountain. A deep shaft will be sunk on this property.—Sinking has been resumed on the Old Abe. Water was encountered at the 1,300-ft. level, a pump installed and sinking resumed. Arthur Greene is superintendent.—At the Hopeful mine at Parsons, owned by the Eagle Mining & Improvement Co. the 200-ton mill is in operation. The capacity of the mill will be increased to 1,000 tons of ore per day. J. M. Rice is president.

SOUTH DAKOTA.

PENNINGTON COUNTY.

The Montezuma Mining Co., one mile north of Rochford, is working 20 men, and has recently uncovered several new orebodies. A five-stamp mill has been erected for sampling and testing ore from the different workings. The object of the company at present is to open up the mine and to determine the best method of treating the ore.—At the Golden West, on Castle creek, 10 men are employed and 50 tons of ore are treated daily. So far, all of the ore handled has been taken from the open cuts.—New battery blocks are being set in at the Stand-by mill, which is undergoing renovation. Twelve men are blocking out ore, of which there is a large reserve. The mill has 40 stamps and will be running within 30 days. V. T. Price, of Rapid City, and J. B. Baker, of Lead, are interested.—The Egyptian-Holy Terror mine at Keystone is working two shifts and the shaft is being sunk at a good rate. A contract has been let to Charles Hall for freighting 50 tons of ore per day from the Egyptian mine to the custom mill. At the Holy Terror no work has yet been done.—Work has been temporarily suspended at the Dakota-Calumet, pending the completion of improvements. Grading is under way at the hoist for two new boilers, and a pump of large capacity has been ordered.

LAWRENCE COUNTY.

Negotiations which began in June for the reopening of the Clover Leaf mine, on Elk creek, have been temporarily suspended. It is expected that something will be done toward financing this property, and it is probable that work will soon be resumed.

UTAH.

SALT LAKE COUNTY.

The Montezuma Co., of Bingham, is shipping silver-lead ore to the United States Smelting, Refining & Mining Co.'s smelter. P. Porter says that the Montezuma will ship from now on at the rate of 150 tons per month.—Adjoining the Montezuma is the Centennial property, in which a drift is being driven to cut the orebody found on the upper portion of the property.

WASHINGTON.

OKANOGAN COUNTY.

A 25-h.p. gasoline engine, an air compressor and two Rand drills have been installed at the lower adit of the Mountain Sheep mine, which is now in 450 ft. At 225 ft. from the portal a vein of low-grade silver-lead ore was encountered, and the face of the adit is now in another vein

of high-grade ore which is known to be seven feet thick.—The shaft of the Copper World mine is down 70 ft. in ore that carries 20% copper and about \$2 per ton gold. The Dominion Copper Co. has bid to smelt this ore free of charge and allow \$1.40 per ton as a bonus. It carries a large excess of iron and also sulphur.—Work has been resumed on the Butcher Boy mine since the bond on it expired. Five men are employed sinking and taking out rich ore.—The Bluffton Gold & Copper Mining & Smelting Co., owning several claims, including a part of the Bolster townsite, near Chesaw, is planning extensive operations. The principal work is on the Bluffton shaft and adits. A body of ore was encountered in the shaft, which was afterward developed in an adit 218 ft. long, at a depth of 150 ft. The face of the drift is in ore that runs \$18 per ton in gold and copper.—The Mad River, Bluffton, Copper Mountain, Olentangy and several other companies are combining to install an electric plant to supply the towns of Bolster and Chesaw, and the mines near by, with light and power.—The Bluffton people have started a new adit to run 1,800 ft., which is calculated to strike the Bluffton vein at a depth of 1,200 ft., and a compressor is to be installed.—The Q. S. tunnel was driven 1,000 ft. when work on it was suspended until the appointment of a new superintendent. Several new claims have been added to the Q. S. group.—F. Moritz has bonded five claims on the north of the Q. S. group. He has also bonded the Germania group of six claims on the south of the Q. S.—The face of the adit, at the Triune mine, on Palmer mountain, is again in ore.—At the Horn Silver mine, on Palmer mountain, several tons of ore have been sacked that is rich in native silver.

Republic, July 25.

STEVENS COUNTY.

(Special Correspondence).—Rich ore is being taken from the Dominion Hill Mining Co.'s property, near Addy, Wash., 73 miles north of Spokane. The vein carries high-grade gold, copper and silver ore. It is announced that ore will be sent to the Granby smelter the last week in July.

Spokane, July 23.

(Special Correspondence).—A 500-ton concentrating mill will be built in Metalline district by Louis Larsen, who has had ground adjacent to the Mammoth mine surveyed for that purpose. He expects to begin the construction of the plant in September.—The Mammoth Mining Co. is working two shifts in its main adit 22 ft. from the portal, on a vein of high-grade silver-lead ore. On the opposite side of the hill another vein has been discovered which is being stripped.—The Morning Mining Co. has purchased 20 more claims adjacent to its own property.—At the First Thought mine the output will be doubled as soon as the aerial tramway is completed. A hoisting plant has been ordered.—Ore has been discovered in the shaft at a depth of 65 ft., which is being shipped to the smelter.—The Stirling mine, in Metalline district, employs 10 men and is getting out ore.—The Dominion Hill Co. is shipping to the Granby smelter, at Grand Forks, B. C. On the adit-level ore is coming in at the face of the drift on the vein, the best of which assays 24 oz. gold and 140 oz. silver per ton. Some of the ore taken from the mine lately assays as high as \$1,200 per ton.—A shaft has been sunk 40 ft. in low-grade ore on the Iron Horse mine, and a company is about to purchase this Cedar Canyon property on account of the large excess of iron in the ore, in addition to the gold and copper content.—The Providence mine, in Cedar Canyon district, under lease, has shipped two carloads of silver-lead ore that averaged \$100 per ton. The ore also contains some copper. There are three veins on the property, two adits having been driven on one of them, one of which is in 552 ft. and heading for No. 3 vein. The Providence Co. expects to install a mill as soon as railway transportation for the concentrate is available.—A large body of gold-copper ore has been encountered in the Butte and Chief mine, near Orient. The Tacoma & Kansas City Mining Co. is about starting work on the Tiger claim where there is a large vein of low-grade silver-lead ore, which carries a little gold. J. A. Frost of Tacoma, Wash., is president of this company.—A pumping plant has been installed at the Bonanza and the mine is being unwatered.

Myers Falls, July 28.

WYOMING.

ALBANY COUNTY.

A. A. Golder, of Boston, agent for the Strong Copper Mining Co., of Laramie, and C. P. Russ, of Haverhill, Mass., who have been at the Strong mine, have decided to build a reduction plant for that property. The Strong shaft has reached the 300-ft. level, developing a body of copper ore. The mine is 14 miles east of Laramie and is owned largely by local men.

LARAMIE COUNTY.

M. G. Grovenor, of Salt Lake, has transferred to the Wyoming Gold & Copper Mining Co., for \$125,000, the Last Chance, Ready Cash and Grovenor copper claims in the northern part of this county.

CANADA.

BRITISH COLUMBIA.

During July the Dominion Copper Co. smelted 18,000 tons of ore producing 404 tons of matte carrying 44.6% copper, which, with gold and silver gave a gross output for the month of \$56,000.—The Great Northern engineers have completed surveying the line to the Pathfinder, and are now at Phoenix to complete some Great Northern surveys in that district.—It is reported that the B. C. Copper is making good headway in developing the Oro Denoro in Summit camp.

At the Ymir mine, during June, 25 stamps crushed 1,500 tons of ore, producing 286 oz. bullion valued at \$3,400 and 150 tons of concentrate valued at \$3,600, making a total of \$7,000 for the month. This was the first month of production since the shutdown. All the ore was extracted in the course of development from all parts of the mine.—The ore shipments for the week ending August 4 from Rossland were: Centre Star, 1,860 tons; Le Roi, 2,970 tons; Le Roi No. 2, 420 tons; Le Roi No. 2 (milled), 1,200 tons; White Bear, 60 tons; total for the week, 6,510 tons; and for the year, 190,229 tons.—At the Trail smelter for the week 6,244 tons of ore were received. Besides ore from Rossland, shipments were received as follows: Iron Mask, Kamloops, 237 tons; North Star, East Kootenay, 139 tons; Providence, Greenwood, 50 tons; St. Eugene, Moyie, 21 tons.—For the first time in two years and a half the Snowshoe is on the shipping list. Following are the tonnage figures for the week ending August 4: To Granby smelter from Granby mines, 15,649 tons; from Emma, 230 tons; to Dominion Copper Co.'s smelter from Brooklyn-Stemwinder, 2,508 tons; from Rawhide, 528 tons; from Sunset, 825 tons; from Mountain Rose, 40 tons; to Nelson smelter from Emma, 100 tons; to Trail smelter from Snowshoe, 125 tons; from Providence, 30 tons; total shipments for the week, 20,035 tons; total shipments for the year, 723,755 tons. The Boundary smelters treated: Granby smelter, 16,400 tons; Dominion Copper Co.'s smelter, 3,901 tons; total for the week, 20,301 tons; total treatment for year to date, 728,350 tons.

NOVA SCOTIA.

The Allan shafts of the Acadia Coal Co., near Stettlarton, are all being lined with concrete, which not only assures safety from caving, but prevents leakage of surface water into the shafts. H. E. Coll has charge of the work. The two shafts are 1,400 ft. deep.

ONTARIO.

The discovery of sphærocobaltite, the protocarbonate of cobalt, at Cobalt, is announced. It has only mineralogical significance.

MEXICO.

For some time miners employed in the Esperanza gold mines in El Oro district have been stealing ore, some of which is worth \$15 to \$25 per lb. Recently the authorities decided to make an example of the thieves. Ten men of the night shift were found with ore in their possession when leaving the mine in the morning, and were placed under arrest. The men were lined up near the mine entrance, a detachment of soldiers was called out and the men were shot within 15 minutes after being taken into custody. The bodies were then allowed to remain where they fell during the entire day, as a warning to other ore thieves.

Personal.

L. S. AUSTIN is at Berkeley.

WILLIAM H. HOWARD is at Denver.

H. G. SCOTT is visiting London from Siam.

THEO. F. VAN WAGENEN is at Zacatecas, Mexico.

G. P. ASHMORE was married at London on August 16.

CLAUDE V. HAINES is on a visit to England from India.

LLEWELLYN HUMPHREYS has an office in Salt Lake City.

ROBERT C. SYSON is on his way to California from London.

EDWARD HOOPER has been examining copper mines in Sweden.

A. J. BENSUSAN is manager of the Ouro Preto gold mines, in Brazil.

THOMAS J. JONES has returned to San Francisco from Salt Lake City.

ALEX. MACKEY is manager of the Eagle Co.'s mines at Parsons, New Mexico.

JAMES COLQUHOUN, president of the Arizona Copper Co., is at Monterey, California.

ANGUS MARSHALL is manager of the Eureka Mining Co.'s plant near Wallace, Idaho.

A. SYDNEY ADDITON is at Dawson; he is expected in San Francisco next month.

W. M. SPAULDING, of Buffalo, has been a visitor in the San Juan country, Colorado.

ARTHUR GREENE is superintendent of the Old Abe mine, at White Oaks, New Mexico.

C. COLCOCK JONES is examining mines in eastern San Bernardino county, California.

EDWIN H. MESSITER, engineer with the Robins Conveying Belt Co., is in San Francisco.

S. HERBERT WILLIAMS, of Boston, is visiting the mines of Ely and Tonopah, in Nevada.

REEVES DAVIS has returned to Oakland, Cal., from a trip through mines in western Nevada.

E. H. HAMILTON is general superintendent of the Arizona Smelting Co. at Humboldt, Arizona.

C. H. SPINKS is superintendent of the American Magnesite Co., at Livermore, California.

EDWIN E. CHASE has returned to Denver from a professional trip to Wyoming and Montana.

HOWARD D. SMITH has returned to San Francisco from examining mines in Sierra county, California.

F. M. SIMONDS and E. Z. BURNS have returned to New York from examining mines in Guerrero, Mexico.

CHAS. A. SHORT is manager of the property of the Jenny Gold Mining Co., at Goldsprings, in western Utah.

H. DEC. RICHARDS has returned to San Francisco from New York; he will proceed shortly to Alaska.

E. H. JOHNSON has been elected president of the South African Chemical, Metallurgical & Mining Society.

D. E. BIGELOW is now at Melbourne; he is chief of the engineering department of Bewick, Moreing & Co. in Australia.

EDGAR NEWHOUSE, of New York, is making an official visit to the smelters of the American Smelting & Refining Company.

T. H. SCOTT has returned to Morenci, Ariz., after an extended trip through the mining regions of Sonora, Mexico and southern Arizona.

N. F. LEOPOLD, of Chicago, has been inspecting copper mines in the Burro mountains of New Mexico, near Silver City, in which he is interested.

J. H. G. WOLF has been appointed chief engineer for the Tonopah Exploration Co. in the installation of water, power, and mills at Manhattan, Nevada.

HENRY M. HOWE and BRADLEY STOUGHTON have formed a partnership for consulting practice in metallurgy, with offices at 27 West 73rd St., New York

Obituary.

R. W. GRISWOLD, a mining operator, died July 30 at Colorado Springs of acute pneumonia. He was 32 years of age.

ERNEST W. HENKLEMAN died at his home at Columbia, Cal., last week. He had been a miner in that district for 50 years, was a native of Germany and 80 years of age.

JAMES MCKINTY, who two years ago was appointed superintendent of the Consolidated Virginia and California mines, at Virginia City, Nev., died July 26 at his home in Virginia City, aged 58 years.

ERNEST H. WEBSTER died a few days since of typhoid fever at the City of Mexico. He had been employed at the mines of the Perico Mining & Exploration Co., at Jilotlan de los Dolores, State of Jalisco.

Trade Treatises.

THE FALKENAU ASSAYING Co. is permanently established in its large, new laboratories at 918 Washington St., Oakland, Cal. Its present quarters are superior to those formerly occupied at 538 Sacramento St., San Francisco.

The Procter & Gamble Co. has just purchased of the ATLAS ENGINE WORKS, Indianapolis, Ind., 4,000 h.p. of Atlas Water Tube Boilers, which are to form the boiler equipment of this company's new plant at Staten Island, N. Y. It is intended to make this one of the model factories of the world.

Dividends.

THE BUNKER HILL & SULLIVAN MINING & CONCENTRATING Co., on August 6, paid dividend No. 107, of \$180,000, making the total paid since January 1, 1906, \$1,440,000, and total to date \$6,966,000.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

THE great inequalities of the earth's surface are the result of unequal radial descent of the surface due to contraction brought about by cooling. Mountains represent portions of the exterior where it has been thickened by abundant sediment and then exposed to lateral crushing with proportionate upswelling.

THE noted copper ore deposits of Copper Basin, Ariz., are 11 miles southwest of Prescott. These deposits are the result of the oxidation of cupriferous pyrite occurring in granite and porphyry, and the impregnation of the local gravel deposits overlying the granite with copper carbonate, deposited from solution.

IN PLACES far from railroads, where materials have to be transported over difficult and dangerous trails, tanks may be made by constructing cemented basins in the ground. This may necessitate pumping, but, as pumps are necessary in any event around cyanide plants, the cemented tank affords one way out of a difficulty.

QUICKSILVER has never been found in large quantity in Siberia, although traces of it exist in many parts, as, for instance, near Minousinsk, also in the Nerchinsk district and along the shores of the Okhotsk sea. No deposits are worked, the Russian quicksilver coming from the Auerbach mines, of the Ekaterinoslav government in southern Russia.

THE contributions that are supplied to moraines by glaciers themselves, from the abrasion of the rocks over which their ice passes, are minute compared to the accumulations which are furnished from other sources. These great rubbish heaps are formed almost entirely from debris which falls or is washed down the flanks of mountains, or from cliffs bordering the glaciers.

AN AUTHORITY on cyaniding gold and silver ore says that the acidity of ore may be neutralized by the simple washing with water to remove soluble salts, or washing with lime-water or caustic soda, with preliminary and subsequent water washes, in more obstinate cases. The most simple method is by intimately mixing the necessary amount of lime with the ore and soaking with a sufficient amount of water.

ORE containing antimony is usually difficult to cyanide. Such ore will probably give better results after roasting, but this must be carefully done, for with the volatilization of the antimony (or arsenic) there is always some loss of gold. Antimony, however, passes off at a relatively low heat, and after that mineral, or its compounds, has been volatilized, the heat may be raised to bring the other sulphides to a 'dead roast,' in order that no soluble sulphates may be formed, which would result in a strongly acid solution, that would have to be neutralized.

ORDINARILY we give no attention to communications requesting information when the writer fails to give his name and post-office address; but the careless miner, at Searchlight, Nev., who signs his letter 'A Subscriber,' is evidently careless about other things as well, and apparently contemplates self-destruction in attempting to make an electrical device for firing blasts. Machines are made for the express purpose of firing blasts by electricity, and manufacturers make primers that are perfectly safe to handle, only requiring to be attached to the wires connecting with the firing machine. These de-

vices are advertised in the columns of the MINING AND SCIENTIFIC PRESS, as Mr. Subscriber could readily ascertain. It would be extremely dangerous for anyone to attempt to rig up an impromptu blasting-machine by means of dry batteries and 'home-made' primers. Never, under any circumstances, insert a wire, pin, or other instrument, into a cap intended for exploding dynamite, and commonly known among miners as 'giant-caps.' The material contained in these caps is mercury fulminate, an explosive of high power and extremely sensitive to shock, abrasion, electric spark or fire. While the dynamite, even No. 1, is comparatively safe, the detonators are very dangerous, and their misuse is probably responsible for the greater number of accidental explosions of nitro-powder.

THE placer mining query submitted by the Waldo, Ore., correspondent is interesting and unusual. The proposition to drive a drift through bedrock from a point on the canyon side and somewhat lower than the apparent bottom of the channel exposed on the face of the cliff, is all right, but the grade suggested—four per cent—may prove too light and four and one-half to five per cent is better where available, as it undoubtedly is, in this instance. The character of the gravel to be washed is probably unknown and can only be judged by what is seen upon the surface, and this may be misleading. The bedrock adit must therefore be started sufficiently low to admit of at least four and one-half per cent grade, and to be sure to strike as low as the lowest stratum of gravel when it reaches the channel, or better still, be a little below it. Apparently the grade of the channel, on bedrock, is not over 200 ft. per mile, as bedrock 400 ft. deep at the dam runs out at the surface in a distance of two miles, which is a little less than four per cent. If the proposed adit, to be driven through bedrock to the channel above the land-slide, is properly planned, the rest seems easy. It might be as well to sink as to raise through the gravel owing to danger from runs, which may be expected to occur should the gravel be saturated with water, as it probably is. When the raise is completed and the sluice has been properly placed in the adit, mining may be commenced by sluicing into the shaft, the surface gravel around its mouth to be carried over the riffles in the sluice discharging into the canyon at the mouth of the adit. Care must be constantly taken to prevent caving of the bank, as such occurrence might prove disastrous. In time a funnel-shaped pit will have been formed reaching from the surface to the level of the adit. Still proceeding carefully, to avoid the caving of greater masses of gravel than the entrance to the adit in the pit, or the sluice itself, can accommodate, the magnitude of operations can gradually be increased when a sufficient area has been denuded to bedrock about the upper end of the adit. When there is no further danger of choking the sluice, or entrance to the adit, mining may be carried on by hydraulic method, to the maximum permissible under the conditions then existing. The only real mining problem involved is in making connection between the upper end of the adit and the surface through 400 ft. of gravel of which nothing is known. If it is light, small, wet, and easily washed there would be trouble in raising and there might be also in sinking, but the latter method affords better means of control. The connection should, in our opinion, be made by sinking and substantially cribbing the shaft from top to bottom, as a collapse of the shaft at any time before the funnel-shaped pit has been formed might necessitate the extension of the adit and the sinking of a new shaft. While the surface pit is forming, the upper timbers of the shaft may be removed as fast as they are reached in the course of mining operations.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Unrest in Mexico.

The Editor:

Sir—The recent trouble with the Mexicans at Cananea has attracted a great deal of attention from the American press to the general trend of border affairs. Since then much has been written of strikes and menacing revolutions, with threats to drive Americans from the country. To the Americans in Mexico, and those along the border, this is all too familiar. The press reports have been strangely accurate, and have caused much anxiety for the personal safety of Americans in Mexico and the financial security of their interests.

To those of us in the midst of it, these recent outbreaks are merely croppings of a long existing and steadily growing feeling of unrest and dissatisfaction among the Mexicans. And it is largely natural. When has there been a time of more than a few years when Mexicans were satisfied? A people of volatile temperament, their kinetoscopic government a playground for nearly a century for liberators, emperors and presidents, it ought to be easy to read the signs of the present alarm. Mexico is going to have another revolution; the date of it depends on how soon they can find a strong man ambitious and foolish enough to tackle it. The fact that they have revolutionary headquarters at St. Louis, Mo., and are spreading circulars inciting trouble, and unearthing old grievances and old war cries of "Mexico for Mexicans," and that the Western Federation of Miners is reported to have helped in this stirring up, are merely natural side-shows of a popular-price melodrama.

Of course, all this is serious enough to Americans in Mexico, and to the safety of their interests, but I don't think it is an anti-American outbreak any more than it is against Diaz and his government; against Terrazas and his ill-gotten wealth, and anti-everything that the *peon* class in Mexico hasn't a hand in and never can have.

Porfirio Diaz has governed Mexico well—considering Mexico. His government has been satisfactory to most of the better class of Mexicans, because it is partial to them; to the American, because it is stable and protects his interests; and to himself and friends, because it pays well. Besides, he has bettered the condition of the *peon* class. He has encouraged education among them, and fostered their interests as much as possible. Certainly, no Mexican has appeared who could improve on his work as a whole, and the life and death problem just now, on this side of the Rio Grande is to find someone who can carry it on as well.

There is a certain amount of jealousy among the better class of Mexicans toward the American business man and miner in this country. They resent the competition with Yankee enterprise. The necessity to rustle to beat it, goads them. It isn't Mexican. While we have taught them to make money, we have taught them to spend it. We have been good teachers and they adept scholars. Since they have tasted the luxuries their money can buy, it has gone rapidly, and the newly poor are apt to be disgruntled. They are jealous and envious of our success, and resent the passing of the mineral wealth of their country into the hands of foreigners—hence "Mexico for Mexicans."

The Mexican *peon* is better off now than he ever has been, and were he left alone and properly managed, he would be contented. But he has been told that he ought to get as much wages as the American, that the company

commissary is robbing him. Mexican labor must be handled by skilled hands, and entirely differently from the labor of the States. His wages depend upon his earning power up to the cost of his living, and above that on his popularity as a host, the size of his family, and the number of his friends—in short, the eating and drinking capacity of his house. His aim in life is a living, and his efficiency as a laborer depends upon his getting little more than that. If a district demands high wages, it also calls for high prices in the commissary. The *peon* can't stand prosperity. The possession of *cinco pesos* so demoralizes him that he is physically and mentally unable to work.

The *peon* may be incited into revolt and stirred against the American until he strikes the blow, and so fight out his patriotism. He will gain little. Even the chance of the immediate success of the present movement is very remote. Diaz is firmly intrenched behind an army that is loyal and strong, and from the popularity of bull-fights, apparently well-enough fed. Ultimately the *peon* is worse off for his revolution, because his failure will most certainly be punished, and his property, if perchance he has any, confiscated to the loyal friends of the Government.

To us there is another consideration more vital than the *peon's* welfare—our own. Success or failure to him means the same immediate danger to the American while it is going on. In most camps the American has little chance. Outnumbered hundreds to one, he cannot protect himself, and, so far from relief, he cannot escape. He cannot call for aid from the United States. Distances are too great, camps too isolated, and railroads too few. Brooding over grievances, real or imaginary, against the Gringo, safe from apprehension, the Mexican's temptation to shoot is great and the running good.

But the Mexican won't bring down the wrath of Uncle Sam too hastily. History has taught him a lesson. Of the American he is unafraid, but he lives in mortal fear, and highest admiration for the Texan. Most Mexicans believe that if Texas were out of the way, they could invade and capture the United States easily.

I believe that the United States will eventually have to use force to protect its citizens, capital, and interests in Mexico, but the task is an enormous one—another 'negro problem,' more Philippines, another addition to the white man's burden—and as long as we have a Diaz to shoulder the work for us, let us watch and learn how. Our troubles will come soon enough.

A GRINGO.

El Paso, July 26, 1906.

Too Perfect for Use.

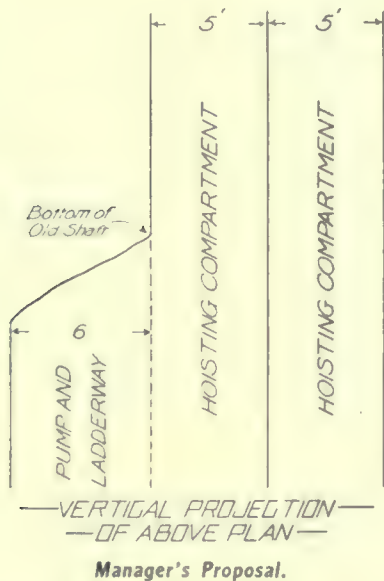

The Editor:

Sir—There have been several articles in the MINING AND SCIENTIFIC PRESS recently, dwelling upon the merits and requirements of a good foreman, and the last one, an extract from a pamphlet entitled 'The Business of Contracting,' reminds me of a parrot story.

During the eventful days of last April, a lady was seen carrying, among a numerous array of bundles, a poll-parrot. She was making her way toward the ferry building, and the parrot, who had evidently passed through a strenuous period, was occasionally giving vent to his feelings in expletives most profane, to the great mortification of his mistress, who would reprimand polly with "Hush up polly; shut up, etc.," until polly, thinking, perhaps, of more dangers to come, was overheard to remark: "Oh, damn it, this is the limit."

Now, Mr. Editor, some of the previous articles on the foreman have been very good, in fact enough was said on what he should be, but this last one must be a perfect

paragon, a blending of angel and tyrant, a philosopher and diplomat, he must take his whisky alone. Of course, he must have begun at the bottom to know a day's work; he must have passed the chairs, so to speak. It is a foregone conclusion that such a man would not remain a foreman. He would rise. Why? Because there is more pay higher up, with generally, less knowledge of the business required than the foreman possesses. Ten to one

that the foreman is only receiving a salary of fifty cents or, in rare cases, one dollar per day more than the men he bosses, yet, according to the pamphlet quoted, he is the man who makes the money for the firm. Then why should not he be paid a salary adequate to his services? No wonder such foreman are scarce as hens' teeth.

The best foreman of a mine I ever knew was illiterate, not much of a worker himself, yet he knew how; he would hob-nob and drink with anyone, and get drunk too; but he could handle men, and distribute labor to advantage, he was very successful as a foreman, and held his job under the late Alvinza Hayward for many years.

I have worked under many foremen good and bad, which convinces me that a man for his proper calling is born and not made. But the one that is required in the article quoted above, and to call him Mr. too, bah! let me shake hands with polly.

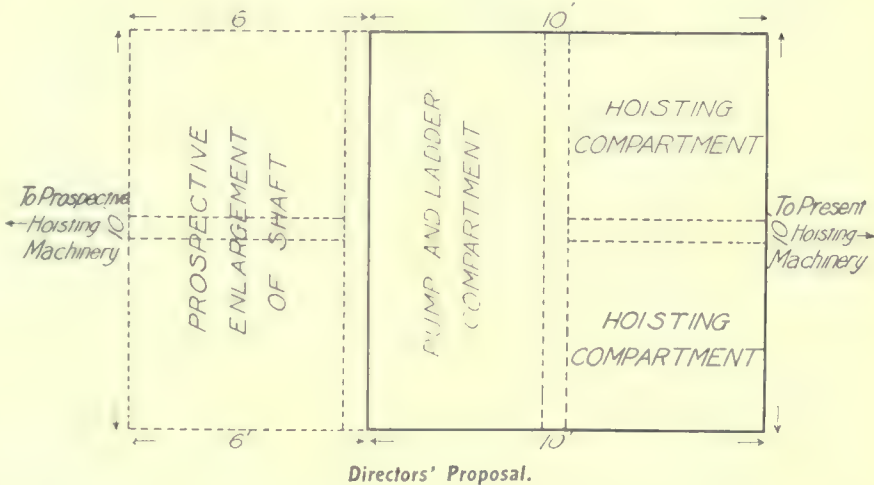

Oakland, July 30, 1906.

CALCIUM-SULPHIDE is known to occur in nature only in meteorites, in the form of pale brown globular inclusions.

The Best Shape for a Shaft.---I.

The Editor:

Sir—Within the past half year there has been carried on through these columns an interesting discussion on the 'Best Shape for a Shaft.' The discussion arose over the problem presented by R. H. Burrows, of Guanajuato, in the issue of Feb. 24, and which may be briefly stated as follows: It having been proposed at a mine near Guanajuato to sink a shaft to a depth of 2,300 ft., the question arose as to the availability of an old Mexican shaft 10 by 10 ft. which had been sunk to a depth of 320 ft. years previously. It was anticipated that it would, in time, become necessary to hoist through the proposed shaft, at least 1,000 tons of ore daily, and the possibility of encountering a large volume of water in the deep shaft was also to be considered. This suggested a shaft of liberal dimensions, but as the manager and directors of the company did not wholly agree upon the 'Best Shape for the Shaft,' the question was submitted to the readers of the MINING AND SCIENTIFIC PRESS, with a request for their opinions. This appeal resulted in numerous suggestions being offered by practical and experienced mining engineers. A resume of the opinions of these contributors is of value. The manager of the Mexican mine in question was of the opinion that for the stated requirements a three-compartment shaft 5 by 16 ft. would be sufficiently large, admitting of two hoisting compartments, each 4 by 5 ft. with a pump and ladder-way 5 by 5 ft. The walls being hard and firm would permit dispensing with wall-plates, thus economizing timbers which are expensive in that district. This scheme also contemplated saving the excavation of two feet of rock otherwise necessary to make room for the wall-plates. The manager proposed to make use of the old 10 by 10 ft. Mexican shaft by dividing it into two compartments, allowing a space 6 by 10 ft. for two hoisting compartments, leaving a space 4 by 10 ft. for pump and ladder-way. At the bottom of the old shaft, however, it was proposed to change the form from 10 by 10 ft. to 5 by 16 ft., cutting a jog at the

bottom of the old shaft, and curving the pipes, etc., to pass from one of the compartments in the 10-ft. square portion to the enlargement, below 320 ft. in the new portion. When submitted to the directors, the plan of the manager was opposed by them with vigor, but they were not without a substitute, and suggested that the better scheme would be to carry down the shaft as originally cut by the Mexicans, or perhaps it might be improved by making it 10 by 11 ft. They claimed: (1.) It would cost little more to sink a shaft 10 by 10 ft. than it would one 5 by 16 ft.; (2.) A deeper cut might be made in the 10 by 10 ft.-shaft than in one 5 by 16 ft.; (3.) The shattering of the sides of the shaft would be much greater, or the

MINER.

number of short holes required to square up after each round would be more in a shaft 5 by 16 ft. than in one 10 by 10 ft.; (4.) A shaft 10 by 10 ft. would give the same number of hoisting compartments and a larger compartment for pump and ladder-way, and general pipe and electric wire purposes; (5.) In view of the possibility and probability of a later necessity for a large hoisting capacity—larger than possible or advisable for two hoisting compartments—the enlargement of the 10 by 10 shaft to a 10 by 16 ft. shaft, which is shown in the accompanying sketch, would give four hoisting compartments, and one pump compartment in the centre, and could be accomplished more quickly and cheaply than by sinking another hoisting compartment 5 by 6 feet.

The proposition at once attracted the attention of engineers and the problem was discussed at length in all its phases during several succeeding weeks.

It was shown by W. H. Storms that a shaft 5 by 16 ft. was sufficiently large to permit the hoisting of the maximum amount of rock that would probably be required—1,000 tons per day. The same writer called attention to the fact that in the proposition to make the shaft 10 by 16 ft. no provision for guides, pump column, etc., had been made, without which the operation of the mine on the scale contemplated would be impossible. He also showed that the 10 by 10 ft. shaft could be divided by steel I-beams into four compartments of equal size, three of them being fitted with guides for either cages or automatic dumping skips. The proposal to make an offset in the shaft at 320 ft. was opposed by Mr. Storms and by nearly every other contributor to the discussion, as impracticable.

D'Arcy Weatherbe showed that when the old Mexican shaft had been divided into two hoisting compartments and a long, narrow pump compartment, and these had been properly timbered, there would not be left sufficient room to handle the large tonnage desired. He suggested first cutting the shaft 18 ft. 4 in. by 6 ft., providing three hoisting compartments, each 5 by 6 ft. and leaving a compartment 3 ft. 2 in. by 10 ft., representing that part of the Mexican shaft outside of the straight line of three hoisting compartments. Mr. Weatherbe submitted an alternative proposition to enlarge the shaft to 21 by 6 ft., making three hoisting compartments 5 by 6 ft. in a straight line, with a pump and ladder-way compartment at one end 2 ft. 8 in. by 6 ft. clear. Both of these schemes contemplated the use of 10-in. dividers throughout, but, owing to the high cost of timber and the desire on the part of the management of the mine to economize, provided for no wall-plates, which omission seems to weaken an otherwise practical idea. He says, however, that "It is hard to conceive of a shaft of such a depth and producing such a daily amount of ore to be constructed without properly framed sets."

H. R. Plate, in discussing the proposition, dealt more with the mining features, assuming that the shaft was to be sunk with machine drills. He contended that it would be more convenient and expeditious to work on horizontal shaft bars in a shaft 5 by 16 ft. than in one 10 ft. square. He also called attention to the necessity for a substantial timber frame, and argued that it would prove false economy to omit timbers. The difference in cross-section between a shaft 10 by 10 ft. and one 5 by 16 ft. is considerable—20 sq. ft.—and this in 2,000 ft. of sinking would make a total difference of 40,000 cu. ft., or over 3,000 tons more of rock which must be shoveled and hoisted in the 10 by 10 ft. than in the 5 by 16 ft. shaft. To this Mr. Plate also calls forcible attention.

Thos. H. Leggett considered that a shaft 5 by 16 ft. was best suited to the requirements of this particular case, and characterizes the suggestion made by Mr. Storms that the shaft might be continued as started 10 by 10 ft.

as "a very practical but perhaps costly method of utilizing the old shaft." Mr. Storms favored the 5 by 16 ft. shaft, and only suggested that the shaft might be sunk 10 by 10 ft. employing steel I-beams instead of timbers. This scheme, however, was not recommended. Mr. Leggett is also of the opinion that the 10 by 16 ft. shaft was out of the question, as unnecessarily large and expensive. He also said that through two properly equipped hoisting compartments much more than 1,000 tons may be hoisted daily from a depth of 2,300 ft. Mr. Leggett also properly says, the difference in the amount of ground that may be broken in a square or rectangular shaft of large dimensions is unimportant. He also considers that steel I-beams four inches broad on the flanges would be an amply strong frame as a substitute for timbers. He concludes by saying, "I much prefer a compartment 5 by 6 ft. to that of 4 by 5 ft. for deep shafts, though I have no doubt the latter can be made to answer all requirements."

John A. Church says that timbering in a large, deep shaft is indispensable, and that "the shape of the shaft cannot affect the size of timbers used, which will be determined by the weights and speed of hoisting." He also says: "The effort to reduce costs by cutting out some of the timbers—the wall-plates—does not seem practicable. * * * * Especially must the timbers that carry the guides be well braced, and also supported by posts. Otherwise they are likely to be torn out by the swiftly passing cage. * * * * I doubt if any system of timbering which omits wall-plates can be considered trustworthy in a shaft of the depth and output given in this case. * * * * It is evident that the question of timbering is the most important of those brought up except, perhaps, the limitations of a shaft for such heavy work to three compartments."

August 2, 1906.

W. H. STORMS.

URANIUM IN AUSTRALIA.—A find of carnotite is reported from Olary, on the Broken Hill railway line, 257 miles from Adelaide, South Australia. The ore is said to occur as yellow incrustations and disseminated powder on faces and cavities in the lode, which consists chiefly of magnetic iron oxide, with black mica and quartz. The main lode is traceable for about 200 yd., either continuously or in isolated exposures, and as scattered float. A smaller similar parallel lode accompanies it on the eastern side at a distance varying from 5 to 15 yd. Traces of ore occur at intervals along both lodes, but are more freely developed along some 50 ft. of the more solid and continuous portion, which varies in thickness from two to three and one-half feet. The specimens brought to Adelaide were obtained by breaking portions of the lode which outcrops above the surface.

It is beginning to be recognized that industrial warfare is no better a regulator of business than private warfare is of social intercourse, and it is this feeling that has led to the organization of labor on the one hand and to the organization of capital on the other, labor seeking to reduce its hours and increase its earnings, and capital, which is crystallized labor, striving to prevent the dissipation of that which it has so laboriously gathered. Each is wrong in its aims when it seeks exclusive domination; both will be right when they learn that they are forces which must work in harmony to carry out the ancient command to subdue and replenish the earth. Strikes and trusts are the clumsy attempts of the giants, Labor and Capital, to carve out each a world on which he shall be sole lord. Co-operation will be the form in which they will work together when they realize, as they are coming to do, that as enemies they can only harm each other while as allies they are masters of the world.

Copper at Butte, Montana.

Written for the MINING AND SCIENTIFIC PRESS
By ARTHUR H. HALLORAN.

During 1905 nearly one-quarter of the world's total copper production came from Butte. The cessation of its output would seriously cripple industry, but such stoppage is fortunately not among the probabilities; on the contrary, copper in this district is now being found in ever-widening zones, where its existence heretofore was questionable. In depth it has been proved to 2,400 ft. in the Anaconda. To the north, North Butte's recent phenomenal production but points the way for further research. And toward the east, numerous new companies are now inviting public attention and capital. The three dimensions of length, breadth and depth are thus defined.—And even skyward, the copper is traceable in smelter smoke.

This smoke is the bane of the real estate dealer. As a gray pall it hovers over the hills and gulches of the town, effectually shutting out the sunshine. Mountain and flat are barren and desolate; but little vegetation remains to suggest the picturesque appearance of the first settlement, seven miles from the present site of Butte City, at Silver Bow "upon a bend of the stream which forms a perfect figure of a gracefully curved Indian bow, and from the mountain peaks which surround the valley, the glistening waters of the 'silver bow' etched in a shimmering sheen upon a background of fuzzy grass form a striking feature of the landscape." Even the grass has disappeared; a prospector's burro would starve on the rough, barren hillsides; the trees originally there, are now rotting in the mines; all future growth is prohibited by this blasting breath of sulphurous fume. Yet even the smoke can scarcely be said to be a blemish upon this inspiring scene, for it bears continuous testimony to useful metallurgical activity. Close to the divide from which the waters run to the Pacific and Atlantic, the elevation of 5,500 ft. affords the pleasant climate and beautiful scenery characteristic of a mountainous region. For the enterprising American it holds that most seductive attraction, money, in the form of the metal copper. The probable increase of this commodity is caused by a series of events, commencing with the success of North Butte and apparently culminating in the formation of the Butte Coalition. The two extremes in this series are themselves directly opposed in effect. For the success of North Butte has encouraged the formation of numerous new mining companies fringing the united claims of Butte Coalition. It is by these alone that Butte is insured from becoming a 'one-company camp,' terrifying to the miner in its prospect of reduced wage and privilege. Now that Mr. Heinze has buried the hatchet, these new companies are in the market, either competitors of Amalgamated or ready to be bought up. But today the Amalgamated is Butte and Butte is the Amalgamated. Tomorrow, as ever, is problematical. A letter from Mr. John Gillie, general superintendent of the Anaconda Copper Mining Company, gives an entrance to all the Heinze properties. The Montana Ore Purchasing Company is moribund. The Heinze-Amalgamated copper war is finished, bruises are rapidly being healed and expert witnesses are seeking new fields of unrest.

This, then, leaves two factions, broadly distinguished, not only personally, but also geographically. For the new companies, with but few exceptions, are now prospecting in what was formerly declared worthless ground, lying to the north and east of the big copper producers. The ground in which they are working has received but little attention from the geologist. Naturally every attempt is made to connect veins cropping across the 'flat' with those on the 'hill.' In order to have an in-

telligent comprehension of this possible connection a brief outline of Butte's geology, as worked out so far, is necessary.

The Butte granite, intrusive in Cretaceous sedimentaries, is itself successively intruded by aplite, quartz-porphry, and rhyolite, the whole complexed by different series of faults. It is these that have had the most important bearing on the deposition and distribution of ore. The fractures in the original igneous rock have been filled, some by dikes, some by veins; some of them displace both dikes and veins. The veins are sharply differentiated as silver and copper, but many of the former become cupriferous in depth. There has been much speculation as to the relation between these silver and copper veins, but as this article deals with Butte copper, the silver question must be temporarily shelved.

Perhaps the best idea of the structural changes affecting this great granitic mass can be gained by looking south from the mine office of the Butte & Bacorn Mining Co., three hundred yards north of the horseshoe bend of the Great Northern railway. To the left and east towers the main range of the Rocky mountains, stretching twenty miles south to the snow-capped peaks of the Highland mountains. To the right and west rises Anaconda hill, with its north and south prolongations. Between these lies a long narrow depression known as the 'flat.' Evidently it was here that the first faulting took place when the continental divide was formed. Its scarp rises precipitously and represents a vertical displacement of at least a thousand feet, the lateral throw being at present indeterminate. This would have made Anaconda hill higher than the main range of the Rockies before the block settling occurred. Naturally the country near the displacement would be much broken and readily attacked by erosion, thus forming the 'flat.' Subsequently a lake occupied this basin, its sediment and a torrential wash now extending to a depth of as much as 600 feet.

Perpendicular to this main line of displacement a parallel series of east and west fractures might well have been formed. These possibly determined the earliest system of veins in the district, the great east-west series, embracing many of the large copper producers. As stated in the preliminary report of W. H. Weed*, these earliest lodes were displaced first by a set of fractures having a northwest course, and later both were displaced by a still more recent system having a northeast course. These are spoken of as 'systems' because they comprise numerous faults, all having the same general strike.

The structural conditions, thus briefly outlined, were the chief factors influencing the subsequent mineralization. Weed distinctly differentiates a primary and a secondary mineralization, the former being the normal vein-filling and the latter giving the workable ore. The former are probably formed by metasomatic replacement of the granite through hot ascending solutions which extracted their mineral from other adjacent granitic masses. The intrusive quartz-porphry is closely associated with many of the big copper veins, as in like manner the rhyolite is identified with the silver veins. That it is a necessary adjunct has not been proved. The mineralizing solutions have entered the fissured granite and changed its hornblende and mica to pyrite. Usually, the ore fades into country rock, the well-defined clay selvages and 'slicensides' being due to subsequent movement.

Copper minerals were associated with this pyrite, but the large bodies of chalcocite which have been the chief source of Butte's wealth are undoubtedly due to secondary enrichment. Meteoric waters have dissolved the copper from the lean ores of the oxidized zone and deposited it

* *Bulletin* 203, United States Geological Survey, 'Ore Deposits at Butte, Montana.'

by reaction with pyrite in the zone of secondary enrichment. The upper portion of the big veins consists of iron-stained quartz, carrying silver ore, with but little copper, except in the gouge. With depth, partly oxidized and decomposed copper ores appear and soon change to

or massive on pyrite, quartz, zinc-blende, altered granite and enargite, filling crevices and fractures both in the veins and in the country rock. His theory, as proved by synthesis, is that copper glance, cuprous sulphide, is precipitated from solutions of copper sulphate by SO_2 formed by the

the sulphides, chalcocite, bornite, enargite and cupriferous pyrite.

The experiments of H. V. Winchell have made clear the genesis of the Butte chalcocite ore, which constitutes more than 75% of that extracted. It occurs crystallized

oxidation of pyrite, according to the following reactions:

Chalcocite thus synthetically deposited on pyrite crystals, defies distinction from that found in nature. An important principle governing this re-precipitation must not be overlooked, namely, the relation between erosion and oxidation. If erosion be faster than oxidation, the soluble metal will be carried away from the vein, but if the rate of oxidation is greater than that of erosion, the metal when liberated will be carried down by the descending solutions.

Weed's recent work on the vein-system cannot be better summarized than in an abstract of his own description:

"The evidence is conclusive that the east-west veins have been faulted. The identity of the Original-Parrot and Anaconda lodes is established, the displacement being due to

the Blue vein. Further east the Anaconda ledge is again thrown to the north by the Mountain View fault. The same faulting has displaced the other veins of this part

of the district. The veins of the great producers belong to this east-west system, in which the trend is remarkably uniform. The Silver Bow vein is an exception. There is some evidence to show that certain southeast fractures were mineralized in the earliest vein-forming period, and some of them were re-opened when the latter faulting occurred. These earlier east-west veins differ in structural and mineral

character from the later lodes, and, except where faulted and enriched, lack their high silver content. The northwest fractures faulted the east-west veins,

and of these the three largest—the Blue vein, Mountain View vein, and Grey Rock—are mineralized, but not so generally as the older veins; the ore occurs in shoots; it is high grade and shows enrichment. The Blue vein has been developed for a mile, and to a depth of 1,000 ft., proving a heavy producer in several mines. The veins of both the east-west and the northwest systems are cut and displaced by those of the northeast system. The best example of this is the Rarus fault, for the ownership of immensely valuable orebodies has hinged upon the geological conditions in the Rarus and adjoining claims. A careful examination of all the accessible workings has proved that the Rarus faults have displaced all the veins. The cut-off is as sharp as if made by a knife, and high-grade ore abuts against the fault-breccia. The veins displaced are so close together that in many places the cut-off ends of different veins are opposite. The fault is compound, consisting of two fissures, the easterly with a dip of 45 degrees, the westerly with a dip of 30 degrees, and these fissures differ in strike. The block of ground between them is crushed, the included vein-segments are broken and their orientation is disturbed by a tilting of the block. The actual fault-fissures are marked by attrition-clay containing rock and mineral fragments. When hardened by infiltrating solutions this mixture resembles the quartz-porphyry. As the material between the faults contains workable orebodies, stoping is sometimes continuous from one vein, across the fault, to another. Whatever the legal decision may be, there is no geological continuity. There has been some ore deposited in the fault-fissures, but not sufficient to form a new north-south vein along the fault, being confined to the proximity of older ore, upon and about which it was precipitated."

It is to be noted with regret that the vein systems thus defined include only those on Anaconda hill. The great deposits of alluvium separating this hill from the main range cover all the outcrops, and what little work has been done in this area but complicates a tangled problem.

There seems to be only one reason why the big copper deposits should be confined to the hill. Winchell's work on the theory of secondary enrichment implies an absolutely free circulation of solutions. Anything hindering such free circulation will allow the copper minerals to remain in the upper part of the vein, but is not likely to allow any re-precipitation in depth. In other words, the vein will contain the original copper minerals, but will not be enriched by a secondary precipitation. The existence of great masses of rock that look as though they have slid off the main mountain range since the time of the first block-faulting, would suggest that in slipping they may have choked the channels and prevented a free circulation. There is apparently no present means of determining whether this sliding took place before or since the most active period of secondary enrichment. There are a number of newly formed companies working in this vicinity, but no great depth has been reached as yet. As might be expected with a poor circulation of meteoric waters, the croppings are excellent, running high in copper. It is to be hoped, and even expected, that such indications will lead to ore in depth. In a number of cases the strike and dip of the veins correspond with those on the hill.

THE practice of hardening steel dates back to the remotest antiquity. Homer, Pliny, and Lucretius refer to the hardness imparted to iron taken from the forge and plunged in water. The ancient Egyptians heated meteoric iron in the forge at a temperature somewhat below the melting point until it had absorbed enough carbon from the fuel to give it the requisite hardening properties, and then fashioned their weapons and tools from the metal thus obtained.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

The fragment of water-worn cobble, marked No. 1, Rampart, is Olivine-basalt.

Of the two rocks from Barron, Wash., No. 1 is Feldspar-porphyry and No. 2 is Quartz-porphyry.

The rocks from Scott River, Cal., marked H., are Sericite-schist and Mica-schist, the latter containing much quartz, and stained by iron and manganese oxides.

The ore from Independence, Cal., marked F. C., is evidently igneous rock heavily impregnated with iron oxide. Iron ore of this description is frequently gold and silver-bearing, and occasionally forms the outcrop of copper sulphide ore.

The three samples from Inyo county, Cal., marked H G., may be described as follows: No 1. is a cellular quartz stained with iron oxide, and containing a little yellow ochre. Gold is also visible in numerous places. No. 2 is a fragment of a diabase dike, in which occurs a veinlet of calcite. Ordinarily we would not expect to find gold in rock of this character but its occurrence in dike rocks is not unknown, and it is not at all improbable that the gold occurs chiefly in the calcite seam. No. 3 is apparently from a seam of calcite in a quartz vein. It shows no sign of containing either gold or silver, but this can be determined by assay.

METALLIC TELLURIUM is extracted from the slime which is the waste product of the electrolytic process employed at the Baltimore copper works in the treatment of copper-mattes from the West. This residue, after the removal of silver and copper, consists principally of the sodium salts of silicic, selenous, and tellurous acids, the last named being in large excess. The method consists in the precipitation of the metal and its conversion into basic tellurium nitrate, $\text{Te}_2\text{O}_3(\text{OH})\text{NO}_3$. This finely crystallized salt serves as an excellent means of obtaining pure tellurium. The basic nitrate is decomposed by heat; the oxide thus obtained is dissolved in hydrochloric acid; and from this solution the metal is re-precipitated by means of sulphur dioxide. Crystallization of the basic nitrate from a nitric acid solution removes selenium completely from the tellurium, and also furnishes a convenient method for the separation of other metals.

EDWARD WHYMPER, CLARENCE KING and other mountaineers with powers of scientific observation have noted that it is at night that the great falls of rock take place. It is due to the freezing of the water which has trickled during the day into the clefts, fissures, and cran- nies. As the sun goes down the action of the frost serves as a lever to shatter and loosen the rock. Whymp- er says that in each of the seven nights which he spent upon the southwest ridge of the Matterhorn, at altitudes of 11,844 to 12,992 ft., the rocks fell incessantly in showers and avalanches.

THOSE who would, but cannot, stand upon the highest peaks may console themselves with the knowledge that they do not usually yield the views that make the strongest and most permanent impression. Marvelous some of the panoramas seen from the greatest peaks undoubtedly are, but they are necessarily without those isolated and central points which are so valuable pictorially.

Ketchikan, Alaska.

Written for the MINING AND SCIENTIFIC PRESS
By H. W. TURNER.

Ketchikan is situated on Revillagigedo island in extreme southern Alaska. It is the first port of entry reached by the Alaska steamers and is the distributing point for Prince of Wales, Gravina, Annette, and other adjoining islands.

The climate is warm and excessively moist, rain falling during the greater part of the year. Snow seldom lies long at the sea-level, but at an altitude of more than 2,000 ft. there is usually a heavy covering during six months. The slopes of the ridges are steep and rugged, but well covered with coniferous trees up to about 2,000 ft. The summits are often quite bare of vegetation or soil; this denudation probably being the result of the scouring of glaciers that appear to have covered these islands at one time. Rocks near the shore, which have

smelters treating copper ores, one at Hadley on the eastern side of Prince of Wales island, and one at Copper Mount on the western side. Much of the ore, however, is shipped south to the Vancouver smelters and to Tacoma, the freight rate in large lots being as low as \$1.50 per ton and the distance carried about 600 miles. Free-milling gold ores, as in the Cracker Jack at Hollis, are known, but apparently they are not abundant. On the eastern side of Prince of Wales island extending from the head of Kasaan bay and Tolstoi Pt. to Cholmondeley sound, is an area of rocks called by the United States geologists Kasaan greenstone. These are probably old andesites metamorphosed and rendered schistose by pressure. Nearly all the greenish minerals they now contain, such as hornblende, chlorite and epidote, are of secondary origin. These rocks are much intersected by dikes of diabase, apparently intruded after the greenstone had been rendered schistose, as the diabase itself is usually massive, and does not exhibit the effects of pressure.

Ketchikan, Alaska.

been protected from weathering by gravel and sand, show glacial grooving and striations plainly and the lake-beds of Prince of Wales island appear likewise to be ravines dammed up by glacial detritus.

The bottom of the numerous inlets of the sea and interior sounds is a marvel of marine life, star-fish of various colors, sea anemones, and even corals are to be noted. These deep, narrow inlets or fiords are an important feature of the region, permitting as they do, steamers of 20-ft. draught to reach nearly all the camps on the islands. Water transportation allows of cheap freight and encourages the mining of low-grade ores, such as occur in most of the mines.

The entire group of islands of the Ketchikan district is fairly seamed with mineralized lodes, the ores being rich in sulphides and adapted to smelting operations. Copper is the most abundant valuable metal; it usually occurs in the form of the yellow sulphide (chalcopyrite), though oxidized ores are found to a limited extent, especially on the west side of Prince of Wales island at Copper Mount and elsewhere. At present there are two

Copper ores have been found in this greenstone at numerous points, notably at Stevenstown, northwest of Hadley; at Mt. Andrews and Karta bay, on Kasaan bay; and near Kiam on McKenzie Inlet, a south branch of Skowl Arm. In all cases the chalcopyrite occurs in grains and seams disseminated through magnetite, ordinary iron pyrite, or marcasite. Locally, in all the mines, rich boulders of chalcopyrite may be found, but they constitute a small portion of the ore. The average content of copper estimated on the basis of a large tonnage is from 2 to 4%. As but little detailed information was obtained of the mines in general, those of the Omar Mining Co., which were carefully inspected, will be more fully described.

The Khayyam mines, operated by the Omar Mining Co., are situated at an altitude of about 2,400 ft. above sea-level, on the summit and north slope of a ridge 2.8 miles in an air-line from Kiam, a post-office on McKenzie inlet. A section of the Powell adit and main workings is shown in Fig. 1. The ore is sent down on an aerial tram one mile long to bunkers and thence trans-

ported 2½ miles over a surface tram in cars to bunkers on the beach, where it is loaded onto boats and shipped to the smelter. The cars are run in trains of six cars each, one train taking about 15 tons of the pyritic ore, which takes about 11 cu. ft. per ton. The trams can transport 300 tons per day of 24 hours.

The Khayyam ore is chiefly a white iron pyrite (presumably marcasite) with disseminated chalcopyrite, and with more or less pyrrhotite or magnetic iron pyrite. It occurs in the form of lenses in the greenstone, much of

ing this warm period, we may imagine that the surface was disintegrated to a considerable depth, and under such circumstances the upper portions of the lodes may be presumed to have been in an oxidized condition, and the copper lodes may easily have had zones of secondary enrichment not far from the surface. This warm period was succeeded by the glacial epoch, when vast masses of ice from the continental region of British America moved southward, covering the islands at least as far south as Vancouver island and Puget sound. The loose and dis-

integrated surface of the late Tertiary may be presumed to have been scoured off by this moving ice-sheet, removing the upper portions of the lodes and any ores of secondary enrichment that existed. It is true that at Copper Mount oxidized ores are said to be found for some distance below the surface, but as these are (in part at least) in limestone, the open spaces along the lode formed by the leaching out of the lime and the consequent introduction of surface influences readily account for oxidation in depth.

As it has been stated that the chief sulphide of the Khayyam ores is pyrrho-

Fig. 1. Cross-Section of Khayyam Mine.

which is a finely fibrous hornblende schist. These schists are nearly vertical and strike about S 75 deg. E, the ore lenses lying about parallel with the schistosity; they are of varying size, several of them crop out at the surface, where they usually show as gossan with some bunches of rich chalcopyrite and considerable pyrrhotite. The gossan is composed chiefly of scoria-like limonite, but not in any large amount. It contains but little gold and silver, and hence is not valuable as ore. The wall-rocks and sulphides immediately under the cropping are irregularly richer in chalcopyrite, which may be due to secondary enrichment. There are, however, no considerable bodies of such ore and the mainstay of the mines is the ordinary marcasite with disseminated chalcopyrite, showing a copper content of not over three per cent. No chalcocite was noted, nor is it to be expected in depth. The ores close to the surface appear to have the character they may be expected to retain in depth. They are essentially pyritic and admirably adapted to pyritic smelting. The zones of secondary enrichment so common in copper deposits are wanting or they are too limited in extent to be of importance.

There is abundant evidence that during late Tertiary time a mild climate obtained throughout the western temperate zone of North America. In late Tertiary deposits we find remains of palms, and of animals the nearest relatives of which now live in warm climates. Dur-

ing this warm period, we may imagine that the surface was disintegrated to a considerable depth, and under such circumstances the upper portions of the lodes may be presumed to have been in an oxidized condition, and the copper lodes may easily have had zones of secondary enrichment not far from the surface. This warm period was succeeded by the glacial epoch, when vast masses of ice from the continental region of British America moved southward, covering the islands at least as far south as Vancouver island and Puget sound. The loose and dis-

Dock at Sea-Level Mine, Revillagigedo Island.

tion of these was made for assay to determine if the precious metal accompanies any particular sulphide. The result, as determined by Lochiel M. King, of Oakland, California, was as follows:

	Gold, oz.	Silver, oz.	Copper, %.
Chalcopyrite.....	0.16	3.60	29.97
Pyrrhotite.....	0.03	0.62	2.67
Impure marcasite.....	0.03	0.40	2.32

The copper content of the pyrrhotite and marcasite is

to be attributed to finely disseminated chalcopyrite, but the much higher content of the precious metals in the chalcopyrite strongly suggests that the gold and silver favor the chalcopyrite. A qualitative test of the pyrrhotite for nickel was made and none found. In addition to the above sulphides, there is a little zinc sulphide present in the ore. The future of copper mining on Prince of Wales island depends largely on the discovery of large orebodies.

Substitutes for Tin.

In the *Mining Journal*, London, there appeared recently an interesting article on the above subject by Mr. L. Parry. He said that in view of the tremendous rise in the price of tin, it becomes a matter of importance to consider the question of substitutes for the metal. The diminution in the price of aluminum, the practically limitless supply of raw material and the physical properties of the metal are facts which must at once appeal to the technical imagination, and point to this—the most abundant of the metallic elements—as a possible substitute for tin. At the same time, it is not the only metal which has to be considered in this connection.

The world's annual production of tin is now about 91,000 tons, and the principal uses to which the metal is applied are in the manufacture of:

A.—Tinplates; tinplate holds from 2 to 3% tin. Two samples recently assayed by the writer contained 2.65% (thin piece) and 3% (thick piece) respectively. The tinplate production of South Wales is probably about 12 to 13 million boxes, and that of the United States about the same. Germany is probably the next largest producer with about 1,000,000 boxes, or, say, 1,350,000 tons for the world's production; the tin in tinplate is stated on good authority to run about 2%, which means that 27,000 tons of metal are consumed for this purpose.

B.—Machine bronzes and brasses; these account for the greater proportion of the world's consumption.

C.—White alloys, such as solder, type-metal, pewter, britannia metal, white bearing-metals. Of these it is important to note the increasing consumption of white bearing or anti-friction metals, which contain tin up to 90%. They also contain 5 to 20% antimony as an essential constituent—a point which may have some bearing on the increased price of antimony. Of other white alloys, we have capsule metal, tea lead, tinfoil, electric fuse metal, accumulator metal, metallic packing, fusible alloys and the various white alloys holding tin which are used for making ornaments and toys.

D.—Ornamental bronzes and gold and silver-plated white metals.

E.—Tin crystals, tin oxide, etc. A considerable amount of stannous chloride is consumed in various branches of textile industry; tin oxide is the principal constituent of many polishing powders.

A.—With regard to tinplate, there is little doubt that many of the uses to which it is applied could be fulfilled by aluminum or galvanized iron, or, assuming the manufacture of such a material to be a practicable proposition, by aluminum plate—that is, iron coated with aluminum. The price of aluminum is now about that of tin, and about fourteen times that of tinplate; and as the specific gravity of aluminum is, roughly, one-third that of tinplate, the cost of aluminum sheet would be about four and one-half times that of tinplate of the same thickness. Aluminum is sufficiently tenacious and malleable to replace tinplate, it resists atmospheric influences well, and, whether as plate or sheet, could be employed in the manufacture of many domestic utensils and vessels used for containing food-stuffs, tobacco, etc. There cannot be much objection (apart, of course, from cost) to its use in

the case of tea, coffee, cocoa, biscuits, tobacco; but in the case of preserved fruits, meat, and vegetables, the objection has been made that aluminum is attacked by organic acids. This is a very important point, and one upon which there is much conflict of opinion; it would seem that the liability of aluminum to attack by fruit acids depends largely on its purity. In any case, we must remember that the aluminum industry is in its infancy, that the power of resistance of the metal to organic acids is a matter which requires investigating, and that we can scarcely condemn its use in such connection on the strength of scanty knowledge available.

B.—Machine bronzes and brasses may contain up to 15% tin, according to the purposes for which they are required. If we put the average percentage at five, we shall probably not be far wrong; and if we remember that the world's annual output of copper is now about 800,000 tons, and that a large proportion of this is employed in the manufacture of machine bronzes and brasses, we see at once that this must mean a correspondingly large consumption of tin. Many of the essential physical properties of tin-copper or tin-copper-zinc alloys may be obtained by the partial or complete substitution of tin by aluminum, manganese, nickel, or iron, though it would, perhaps, be incorrect to say that such an effect could always be produced, or that such alloys would be invariably cheaper. The object of successful brassfounding is the production of a suitable alloy at a profit. If, for instance, the price of tin, aluminum, and nickel happened to be about the same, and it was found possible to obtain the properties required in a gun-metal holding 90 of copper and 10 of tin by adding 1 or 2% each of aluminum, nickel, and tin, to a copper-zinc base, it would certainly pay to do so. A rise in the price of tin should stimulate research in the direction of such combinations.

C.—Of the important white metals, we may say at once that solder and type are required on account of such special and definite combinations of physical properties, that their replacement by other metals to any appreciable extent is quite improbable. With regard to white bearing-metals, again, the tin which is used in their manufacture confers physical properties upon them which can scarcely be otherwise obtained, so that the consumption of tin in their manufacture is likely to increase rather than to diminish.

D.—With regard to ornamental bronzes, it is difficult to speak with any degree of certainty; the use of tin is, however, not an absolute necessity, and its consumption for the purpose has been diminishing for some time. On the other hand, an increased amount of tin is probably now used in the manufacture of white metal ornaments, for example, in the case of white bronzes. Many white metal combinations are employed in making ornaments, and it is probable that the demand with the regard to quality readily accommodates itself to the supply. The quality of such goods probably varies far more than the price; if tin keeps up in price for a year or two, it will probably be found that the percentage of tin in white metal ornaments will diminish considerably. With regard to white metals used as bases for electro-plating with gold and silver, it has already been found possible to use aluminum; the processes are still in their infancy, but no doubt the use of aluminum for this purpose will become more and more common.

THE CRACKS in reverberatory furnaces and in boiler foundations may be chargeable to any one of a number of causes, or to a combination of them. Among these are: Insecure foundation which settles unequally; expansion from heat; poor materials used in construction thrust, due to improper construction.

Secondary Enrichment Upward.

Written for the MINING AND SCIENTIFIC PRESS
By COURTENAY DE KALB.

Cases of re-arrangement of the metalliferous contents of lodes by rejuvenation of the circulation of solutions as a result of later faulting of the enclosing rocks are not uncommon, but the phenomenon which is the subject of this contribution is an instance of true secondary enrichment from normal causes occurring after all movement in the rocks had ceased, and after the solutions had effected metasomatic replacement to the point of complete cementation of the fractured zone.

The writer was engaged in the development of a number of copper claims scattered along the north shore of Lake Huron, and was surprised to find that in many of them a promising orebody near the surface rapidly decreased in copper content until at a depth of from 51 to 25 ft. the copper minerals had practically disappeared. On comparing notes with Major Robert G. Leckie, who had also been exploring the same region for the Orford Copper Co., I discovered that he had met with similar disappointment in a considerable number of cases. Prof. Willett G. Miller likewise reported numerous instances of a similar character in the district east of Lake Nipissing, both in copper and lead veins. The region where these phenomena occurred was extensively glaciated, and, so far as my own experience went, these superficially rich copper veins were all found where the glaciation had produced *roches moutonnees*, entirely bare of vegetation except in the intervening depressions.

Since many of these veins were of large dimensions, and some of them so extremely rich near the surface as to produce quantities of ore running as high as 10% copper, or more, I determined to make a more exhaustive test of one deposit, and ascertain its condition at some depth below the surface. The property selected for the purpose was that known as the Grattan mine, about three miles east of Massey station on the Soo Line of the Canadian Pacific railway, and one mile north of Spanish River. The rocks of the district consisted of quartz-diorite, rising out of the swampy river bottoms in a rolling mass of egg-shaped glaciated domes, the general elevation of which was about 250 ft. above the swamps. Beginning at the swamp, and extending over the summit of one of these domes, and thence traversing the *roches moutonnees* for nearly a mile, was a shear-zone 20 ft. wide, within the boundaries of which were innumerable outcrops of quartz stringers from the thickness of a knife-blade to a foot wide. Elsewhere within the shear-zone, the surface rock appeared to be nothing more than weathered diorite, upon which the lines of flowage induced by the shearing movement were quite generally traceable. On chipping the surface of this flow-diorite, however, an abundance of chalcopyrite was everywhere revealed, quite concentrated at a distance of only one-eighth of an inch below the outer weathered crust, although no sign of the existence of copper minerals was observable until such chipping had been done. A number of test-pits were sunk at frequent intervals along the outcrop of the shear-zone, across the domes and down the steep incline of the southern front of the hill to the edge of the swamp. In every case chalcopyrite, with some bornite, was found in abundance close to the surface, gradually decreasing within 10 ft. to less than two per cent copper. From one-eighth of an inch to two inches below the surface, the copper would generally average from 10 to 15%. This condition was uniform at all altitudes above the swamp, so that the copper-bearing portion of the vein was evidently a mere shell or cap.

A shaft was sunk, starting just above the water-level of the swamp, which was carried down 40 ft., and a drift

was then extended from the bottom 20 ft. under the swamp, at which point water came in so freely that it was deemed unwise to proceed farther. To a depth of 15 ft. the average copper content was three and one-half per cent. Below this the copper and iron sulphides rapidly decreased in quantity, and at 25 ft. the vein was entirely barren of metalliferous minerals, but the quartz in places showed seams which were pitted as if pyrite had been dissolved out of them, and the diorite in the shear-zone was also porous. At a depth of 30 ft. some pyrite began to appear in the diorite, which condition continued without change to the bottom. The most obvious explanation of the phenomenon, of which the Grattan lode furnished a characteristic type, was that the shear-zone may have originally contained a slight concentration of copper from the surrounding diorite; that owing to glaciation, and lack of soil and vegetation to hold water, the precipitation instead of penetrating the rock promptly ran off into the surrounding depressions; that during the relatively short but intensely hot summer the evaporation was so rapid as to induce a movement of an abnormally active capillary circulation upward, the solutions thus ascending carrying copper and iron sulphates which would re-act upon the sulphides of iron and copper in the usual way, forming secondary enrichments near the surface; and finally that, owing to the intensely heated surface of the rock, which often exceeded 120 deg. F., the moisture would be completely vaporized at a short distance below the superficial crust, which crust therefore would contain no copper, whereas the copper would be most highly concentrated at the point of such volatilization a fraction of an inch below the surface, as actually found. The inability of the surface waters to seep into the hard, glaciated rock would preclude any action contrary to this upward concentration of the copper.

The Massey mine is eight miles northwest of the Grattan and is a producing property, presenting similar phenomena. There was no superficial evidence of copper, and, in fact, the mine was discovered through the accident of a belated hunter building a camp-fire upon the bare glaciated outcrop of the vein. The heat split off a shell of the upper rock, revealing a mass of chalcopyrite near the surface. The upper portion of the vein was highly enriched, but the quantity of copper decreased until a fairly uniform average of from three to four per cent was reached at a depth of 90 feet.

AT HASOKURA, in Mongolia, the natives smelted galena in a small furnace or hearth 15 in. diam. with the addition of iron in the form of old coins. The charge was 83½ lb. of ore and the third (last) cake of slag of the preceding operation; 23½ lb. of iron coin, or 19½ lb. of new iron; 58½ lb. of charcoal. The smelting lasted two hours, there being three operations in the morning; in the afternoon the hearth was repaired. The product was about 50 lb. of lead to each operation. The lead (except the poorer part) was cupelled by two women on a hearth of wood-ashes, and the litharge afterward reduced again to lead; with a loss of 25 to 30% lead in the whole process. The monthly product of silver (1¼ lb. avoirdupois) amounted to 0.05% of all the lead.

MOST of the pumice used in the United States is imported from the island of Lipari, in the Mediterranean, where it occurs in enormous quantity. It is mined and shipped so cheaply that little is produced elsewhere. Some pumice has been brought to the Pacific coast in recent years from Hawaii. Any deposit of pumice in the Western States, to be commercially valuable must be of excellent quality and situated where cheap transportation is available. In 1905 the production of pumice in the United States was about 1,800 tons, valued at \$5,500.

An Improved Method of Framing Square Sets.

Written for the MINING AND SCIENTIFIC PRESS
By A. A. STEEL.

Mr. M. K. Orr, one of the mining students of the University of Arkansas, has suggested the plan of framing square set timbers, here illustrated. This plan is the result of a desire to use on all the members nothing but square tenons and shoulders so that each timber can be completely framed with but one setting of the simplest type of machine, such as the Joshua Hendy framing-machine recently illustrated in this journal. For squared timbers this has but five saws at each end and a device for rotating the timber exactly 90 deg. As far as known to the writer all square sets now used have centrally placed tenons. This requires oblong tenons on at least one series of the timbers. These may be framed on a complicated machine, but in practice they are usually framed square and altered later.

Fig. 1, 2 and 3 illustrate Mr. Orr's system applied to round timbers with the usual bevel and top slabbing. Since everything is square and all the shoulders are of the same size, the bevel requires but two additional saws at each end of the machine, and these diagonal saws need never be shifted.

The figures represent the timbers framed for the usual case of greatest pressure downward, so the tenons of the

unusually large, there will be less temptation for the timbermen to saw the bottom of it off rather than clean the socket. It will be expected commonly to fill the socket with a 2 in. plank 10 in. square to keep out the dirt until time to put in the new post. This will afford an excellent foundation for blocking the set against the roof. The tops of the horizontal timbers must be slabbed at a fixed distance from the tenon for convenience in laying a smooth floor.

Besides the assistance of the bevel, the joint shown gives a minimum perpendicular bearing surface two inches wide or of 16 sq. in. to resist displacement of the timbers by blows from flying rocks or by distortion of the sets under heavy pressure. It thus quite simply avoids the greatest objection to round timber sets. It uses the full strength of the tree, which even if figured in simple compression is over one and a half times as strong as the largest square timber that can be cut from it. Owing to the bevel joint there is also less pressure against the side of the thin tenons and they are less liable to be sheared off. Since this framing permits the use at the same joint of all sizes of timber above the minimum, it is easy to increase the strength of the

Fig. 1. Isometric View.

new sets as pressure in any stope becomes greater.

An incidental advantage of Mr. Orr's framing is that the caps and girts are identical, so that less frequent setting of the framing machine will be necessary, and the

Fig. 3. Side Elevation. Round Timbers.

posts touch. The horizontal pieces have 8 by 8-in. tenons 2 ft. long, on the corner of a 10 by 10-in. shoulder. By reference to Fig. 2 and 3 it will be seen that the saws of the machine can be arranged to cut one deep notch on the top of the timber and merely square the tenon on the bottom. When the timber is rotated 90 deg., the same cuts are made upon the former sides and the framing is complete.

The tops of the posts have a central 6 by 6-in. tenon 8 in. long and the bottoms a 10 by 10-in. tenon, 2 ft. long. The socket for the bottom of the post is thus wide and shallow, and the fine ore which falls into it, can be cleaned out with little annoyance. Since the bottom tenon is also

Fig. 4. Plan. Square Timbers.

timbermen will have less bother selecting the required timbers. For the same reason, with round timbers, the smallest caps may be placed always in the direction of least pressure. If the timbers are slabbed on but one side only, adjoining caps must be turned end for end as shown in Fig. 3. Timbers that are accurately sized and squared can be framed the same way. If we imagine the round timbers shown in the figures slabbed on all sides until the bevels disappear, the drawings will represent the framing for 10 by 10-in. pieces. The bottom of the posts will then just fit into the socket with no framing except cutting off square.

In order to make a snug joint without a bevel, and in

spite of any warping of the timbers and irregularity in size or angles, the outside of the tenon may be gained as much as necessary. This will require the same sort of machine as that used for framing squared posts. Fig. 4 is the plan of 10 by 10-in. timbers gained half an inch. They are drawn in position, to show that there will be a clearance of a quarter of an inch next the only uncut side of the timber. This gaining throws the abutting caps slightly out of line. A little study will show how easily larger timbers can be fitted to the joint of small ones.

This new plan of framing has the advantage of greater

Fig. 2. Plan of Framing. Round Timbers.

simplicity of the framing machine, greater flexibility in the size of the timbers and interchangeability of caps and ties. From the last, it follows that the horizontal timbers are equally secure against displacement, fewer settings of the framing machine will be needed and there will be less confusion underground. It is hoped therefore that some mine superintendent may be sufficiently interested to give it a trial.

IN the Colorado desert of California and Arizona, travelers notice large areas covered with a mosaic-like pavement of rounded, polished pebbles, there being few large stones and scarcely any sand among them. These areas glisten in the sunlight and at a little distance may be mistaken for water. W. P. Blake offers the following solution to account for the occurrence of these mosaic mesas: "It appears certain that the surface-sheet of pebbles, and in many localities of small fragment of rock and bits of fossil silicified wood, is the result of an accumulation by the gradual removal, by the wind, of sand, silt or finer materials from around and below the pebbles, undermining them, removing their support, and permitting them to fall to a lower level, where they accumulate by concentration until the whole surface is closely covered by fragments too large and heavy to be moved away by the wind. Such a deposit of pebbles or fragments may thus represent all that were originally distributed through several feet of thickness of sand and lighter alluvions. In this way there may be a removal of a large amount of fine materials from the general surface of a region, lowering its level, until, by the complete covering and protection of the surface by the concentration of the heavier fragments, eolian denudation is arrested, and the further lowering of the surface is stopped."

Repairing a Gold Dredge With Thermit.

The strenuous work required of a gold dredge naturally necessitates many repairs of working parts. These are not always easily made by ordinary means, but recently in California an interesting illustration was given, according to the *Electro-chemical and Metallurgical Industry* of the facility with which thermit may be applied to repairs of machinery in mining fields remote from foundries and machine shops. Thermit is a mixture of finely divided iron oxide and aluminum, and the reaction (which is started

by igniting a special ignition powder with a match, consists simply in the combination of the aluminum with the oxygen of the iron oxide. Since this gives out an enormous amount of heat, the iron set free is obtained in form of a superheated liquid soft steel at 5,400 deg. F. within 30 seconds after starting the reaction.

It is self-evident that it is possible to do many things with such superheated liquid steel for the repair of iron or steel machinery and for other purposes in iron and steel metallurgy. Other practical advantages of the method are the simplicity of the necessary outfit and

the ease of transporting it. The repair referred to was made at Wallace, Calaveras county, to a dredge owned by the Mokelumne Mining Co., of which William C. Colley is general manager. The trouble was principally with the upper tumbler. The driving-wheel to which the bucket-line is hung drives it by sprockets. This bucket-line consisted of 64 buckets, each weighing 1,100 lb. and having 5 cu. ft. capacity. The tumbler shaft was 12 to 13-in. diam., and had a hub keyed to it by two heavy quartering keys. The hub was tapering and 20 in. diam. on the large end. The shell, with the heavy sprockets, slipped over this hub and was drawn over the taper by three bolts, 1½-in. diameter.

Through this fault, probably alignment, the whole tumbler, hub and shell, crept along the shaft, notwithstanding heavy bands designed to prevent this, and through a faulty and slightly large bore of the hub, the keys could not be kept in place and were gradually disintegrated by the working of the hub.

The Pacific representative of the Goldschmidt Thermit Co., L. Heynemann, 2721 Clay St., San Francisco, after examining the shaft and tumbler, concluded that it was possible to fuse the tumbler immovably to the shaft; that is to say, to cast a thermit steel band on each side of the hub, which would fuse both to the shaft and face of the hub. The repair was made in the beginning of April, the tumbler, shaft and hub being placed in a field near the dredge. The heavier end of the hub was treated first. On April 10, after rain in the forenoon, both cores were fitted. On April 11, late in the afternoon, after the shaft had been heated to 'black red,' the reaction took place. The crucible containing the thermit mixture was placed over the mold. On April 12 the cores were fitted for the other end, and by 10 o'clock that night they were ready for action.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

ORE-SCREENING MACHINE.—No. 825,081; Alfred Schwarz, New York, New York.

A screen comprising a plurality of sections secured together by pairs of plates, one pair being of less length than the other and the said sections secured thereto in substantially parallel relation in planes inclined to a horizontal plane, grooved rollers supported by said plates, cam-surfaces upon which said rollers rest and upon which they are adapted to be moved, and means for imparting a longitudinal reciprocating movement to the screen sections.

SEPARATOR FOR USE IN THE CONCENTRATION OF ORES.—No. 825,080; Alfred Schwarz, New York, New York.

In a separator for use in the concentration of ores the combination of a kettle adapted to contain water, shelves supported within said kettle, scrapers co-operating with said shelves to impart a continuous movement to the contents of the kettle, an overflow-discharge outlet at the top for the concentrate and adhesive agent, and a discharge-outlet at the bottom of the kettle for the tailing.

MAGNETIC ORE SEPARATOR.—No. 824,893; Joseph Weatherby, Jr., New Cumberland, Pennsylvania.

In a magnetic ore separator, the combination of a magnet having a pole-piece presenting an inclined surface and an extension of said pole-piece also presenting an inclined surface and forming a shoulder, a cylindrical revolving magnetic carrier element presenting a surface above and moving past said pole-piece and extension and forming an air-gap between them, means to feed material in a thin layer to the air-gap, and means to subject such material, while its move-

ment through the air-gap is magnetically retarded, to force exerted in a direction at an angle to the lines of magnetic force in the air-gap and also at an angle to the plane of movement of such material with the carrier.

ORE SEPARATING AND CONCENTRATING MACHINE.—No. 824,927; Joseph L. Hellyer, Ieonium, Iowa.

In an ore-separating machine, the combination with means for drying and sizing the ore, and a primary ore-treating trunk adapted to receive the ore from the drying and sizing mechanism and containing a shaker-riddle; of a secondary ore-treating trunk mounted beneath said primary trunk, a connecting-pipe mounted between said primary trunk and the receiving portion of said secondary trunk, depending valve-boards mounted in the receiving portions of said trunks, suction-fans mounted in the discharge portions of said trunks, and means for operating said shaker-riddle and said drying and sizing mechanism.

METHOD OF TREATING NICKEL-COPPER MATTE.—No. 825,056; Woolsey M. Johnson, Iola, Kansas.

The herein-described method of recovering nickel and copper from matte, which consists in treating the matte with hydrochloric acid, thereby obtaining a solution rich in nickel and a residue rich in copper, electrolytically separating the nickel from said solution, and electrolytically separating the copper from said residue.

Hydraulic Classification.

Written for the MINING AND SCIENTIFIC PRESS
By S. R. SWAIN.

A hydraulic classifier must fulfil certain requirements, such as sorting column, hydraulic upward currents, settling arrangement, and method of eliminating rejected fine. The sorting column should be given close attention. Upon its diameter depends the maximum capacity, but this capacity will be influenced by the hydraulic pressure and the size of the spigot-product desired. It is obvious that only a certain amount of material can pass a certain opening, and that the hydraulic pressure will lessen the amount according to its force. Also it is necessary that the classified particles should not be crowded too closely while falling in the upward current, for such would cause an accumulation, and the current would lose its control. The length of sorting column will be a matter of even closer study. Upon it depends the nicety of spigot-product. Its length should be such that the upward current will have lost any influence from eddies or counter-currents, and long enough so that the ore particles which are desired as a spigot-product will have sufficient falling space to be thoroughly influenced by the upward current. The quantity of irregular particles in the ore will greatly influence the length of the column, for such particles require longer action for a better sorting.

The hydraulic upward current should be absolutely uniform and under instant control, and its mode of introduction one that will cause the least number of eddies and

Fig. 2.

Fig. 1.

counter-currents. Experiments have shown that an evenly rising current is better than a vortex when the length of sorting column is correctly proportioned.

The method of eliminating rejects is a feature that is best combined with the settling arrangement. The action should be positive and so adjustable as to accommodate any difference in conditions, such as change of feed or amount of water.

It may seem to the reader that the numerous requirements are too vague, but by close attention to the following description and sketch, I believe the simplicity of the device will be appreciated and the ease of adjustment understood.

Fig. 1 shows sketch of the box or trough. The feed is introduced at A and flows as the arrow points. The inclination of the trough is such as to cause an easy flow that will carry the largest particles along the bottom; a is a fixed baffle-board, whose lower end extends at least four inches into the pocket B; b is a screen, the openings of which are at least five times the size of the largest particles; c is a movable board which is adjustable by the toggles d d by means of connecting rod e. The sorting column D is bolted to the bottom of the pocket so that it is directly under the opening C. The sorting column is shown in Fig. 2, a is a flange for bolting to bottom of the pocket; b is an iron pipe, which with the glass tube d forms the sorting column; c and e are stuffing boxes to tighten the joints at these points. The glass part d of the sorting column is of proper diameter to slip into the pipe portion of it; f is the water chamber; g is the outer tube which through the perforations i distribute the hydraulic water in the annular

opening between itself and the inner tube h; j is the discharge pipe and k is the spigot. The weight is carried by rod p which screws into the flange a, while the nuts q, q on the long thread of the rod are adjustable to varying length. The main hydraulic water is admitted through a gate valve in n and a short hose m to chamber f, and another supply through a Lunkenheimer 'Handy' gate-valve o to the same chamber.

Let us follow the pulp through one compartment, which would be one classification: The ore being fed at A is carried by the water and the inclination of the trough to the first pocket; there it easily passes the screen b, the meshes of which are of large dimension. The tendency of the screen at this point is slightly to retard the finer particles in the eddies formed directly beneath the wires, thus the coarser particles settle, while the fine is kept in agitation and suspension. The pulp passes under the fixed baffle-board a, and directly over the sorting column D. The hydraulic pressure has been regulated for the desired spigot-product. The spigot has a constant opening. The elimination of eddies and counter-currents in the column is accomplished by the peculiar arrangement of water-chamber and the outer tube with perforations and the inner tube which properly distributes the hydraulic. This gives us a quiet upward current which allows properly weighted particles to fall, while those too light are held without the tube. Perhaps the length of tube is not correct for the product desired. A glance at the interior of the sorting columns through the walls of the glass portion of it will quickly tell and its length can be adjusted by means of the slip-joint shown at c in Fig. 2. Should the fine be accumulating over the column in the pocket to the extent that it falls in the upward current, the glass portion of the column will show it, and an adjustment

of the movable board c contracting the opening C will carry this fine to the next compartment.

When an ore of components of similar gravity is being treated, it might be well to have an additional current which would be pulsating in effect and would tend to disperse an accumulation in the top of the column. It can be easily arranged by the use of the 'Handy' gate-valve o, Fig. 2, which can be mechanically operated to open at stated intervals. Another feature would be the connecting of rods e, e, Fig. 1, so that by moving one all would be moved a proportionate amount. This would allow of the changing of carrying water, while by this adjustment the spaces C C could be instantly changed to the proper size for disposing of the rejects from the sorting columns.

It will be seen that the combinations introduced in this classifier allow of thorough adjustment, permitting of variations of feed and water without impairing efficiency. The length of sorting column is readily changed to accommodate conditions. The glass portion of the tube allows of interior inspection, which shows the action and immediately suggests any adjustments needed. The scheme may be carried through any number of pockets. The final overflow should be impounded in a settling-box, the discharge of which may be regulated for thickening.

No dimensions are given, and neither is the capacity mentioned, but these can easily be solved by anyone caring to try the device. This classifier is especially adapted to lead-zinc-iron classification, and experiment has shown its fitness for other classes of work.

Editorial.

AFTER AN INTERVAL of 13 years the Government is again buying silver bullion for coinage at the mints. On Wednesday of each week, beginning August 15, and henceforth until further notice, tenders will be received by the Director of the Mint at Washington for the delivery of silver to the mints at Philadelphia, Denver, or New Orleans. The several mints are also now buying bullion containing more than one-half its weight in silver. Heretofore only bullion was received containing more than 10 parts gold to one part silver.

REFERRING TO our comment on the Fresno Copper Company, last week, we learn that Mr. J. S. MacArthur has been chosen by the directors and shareholders to verify Mr. Siebert's report. Mr. MacArthur holds the confidence of people at Glasgow, and elsewhere. It remains but to add that the information given at a shareholders' meeting on July 27 confirms the criticisms and the moral we ventured to offer.

ON ANOTHER PAGE we publish a communication from the Russian consul at San Francisco in which he warns the public against certain doings of the North East Siberia Company. In another journal we made editorial reference to this matter, two years ago, and warned investors or speculators from engaging in these long-distance ventures in a country where it is easy to get mining rights, but most difficult to bring them to financial fruition. In other words, while the American company referred to may have promised more than it can perform, the Government of all the Russias has failed to 'make good' in several Siberian concessions, granted to Englishmen and to Americans.

WE PUBLISH an article describing the method of hydraulic air-compression at the Victoria copper mine, in the Ontonagon region of Michigan. As fuel was expensive, the abundant water was applied in an ingenious manner to the generation of power. How it is done, Mr. C. H. Taylor, the inventor, tells us in his interesting article. Water is taken from the river under a head of 71 feet, and air is admitted into the falling water through a number of small pipes; the water, with the air thus entrapped, is piped through three shafts to a depth of 330 feet, where it spreads into a large chamber cut in the rock. Here the air, now at a pressure of 117 pounds per square inch, rises from the water and occupies the dome of the chamber, whence it is piped to the surface. The tail-water meanwhile escapes through a lower tunnel that communicates with an incline shaft, leading to surface, 260 feet overhead. The air has the low temperature of the water and the loss due to rise of temperature in compression is minimized. The energy thus generated is applied to various kinds of machinery, including

hoists, drills, and stamps. To Mr. Taylor and to Capt. George Hooper, the late manager, is due the credit for this clever application of natural power.

Unrest in Mexico.

The Anglo-American papers published in Mexico are uniting with the local authorities in denying the reports current in our daily press concerning the threatened outbreak among the laboring people, with the cry of "Mexico for the Mexicans." Last week we published a letter from a mining engineer living in Mexico, who undoubtedly wrote in good faith. As far as we can ascertain there is some ground for the fear of an outbreak, especially near the border. The truth lies somewhere between the two accounts; it is not as threatening as the papers on this side of the Rio Grande make out; yet it is more serious than those in Mexico are willing to allow. The difference in wages paid to the native as compared to the foreigner, has provoked protest, and there are enough unruly people to stir up trouble, especially where the management of a mine is not harmonious. The next president is not likely to be another Diaz, who, despite the revolutionary training of his early adventurous years, has proved himself a strong and efficient ruler, thoroughly fitted for his time and country. Mexico is well policed; there is no chance for riot so long as the central Government remains coherent, and even in the separate States the Governors are men well fitted to suppress disorder. But should Diaz be succeeded by a weak man, whose authority could be speedily undermined by an ambitious military leader, the social equilibrium would be upset and under such conditions the laboring classes might rise to protest against the dominance of the foreigner. There is an enormous amount of English and American capital in Mexico, there is also a large foreign population composed mostly of active educated men; it would be no slight matter if either the lives or the money introduced into Mexico during recent years were jeopardized. We do not anticipate it, but a sense of false security is not preferable to one of needless timidity.

In commenting thus, we would be sorry to give color to any of the fabrications that have been printed on the basis of the facts we refer to. During the past week the San Francisco *Call*, and other daily papers, published a tissue of absurdities and falsehoods such as would disgrace even the yellow journals of W. R. Hearst. It was a story that Col. W. C. Greene and other speculators had hatched a conspiracy to create trouble along the border "with the hope that a serious complication would force the southern Republic to cede to the United States the rich mining district of Cananea in Sonora." And in this connection the names of the Venture Corporation, Mr. F. W. Baker and Mr. Ernest Wiltsee, were mentioned as representing English interests that were to draw Great Britain into the embroglio. We have no communication from, or with, these gentlemen, but we know enough to be able to stamp the yarn as an impudent falsehood, concocted to make a sensation among those who happen not to be informed on Mexican affairs.

Cheap Shares.

The Curb Market at New York has become prominent lately. There are about 2,500 brokers 'on the curb'; it is said that in their business is included trading in not less than \$5,000,000 worth of stock having a par value of \$1 per share; from 2,000 to 3,000 corporations have such stock and there are several companies the capital stock of which is at par worth but ten cents per share, some of them having stock of the par value of one cent per share. A court decision that the New York stock tax of two cents per share applies to the par value of stock, whether it be \$1 or \$1,000, has shaken the market on Broad street, so that some of its peripatetic members have gone to Jersey City and some to Boston. The decision affects the cheap shares, such as eleven Tonopah stocks, an equal number of Goldfield issues and nine that represent speculative mining at Bullfrog. There are 35 of these Nevada stocks that sell below \$1 per share, not necessarily because the mines are of small value, but by reason of the large capitalization, divided into an enormous number of shares of small denomination. This is in curious contrast to the practice of the early days on the Comstock when the shares in a mining enterprise were divided into as many feet as it possessed in length of lode, so that a share, equivalent to one foot of outcrop, might sell for several thousand dollars. It is no wonder that they lack water in the desert mining centres of Nevada, seeing how much of it they put into their stocks. The idea, of course, is to put the purchase of shares within the reach of the small dabblers in mining speculation, most of whom prefer a thousand shares at 50 cents apiece to one share at \$500. There is a notion that in buying small-priced shares, the purchaser cannot lose much; this is a fallacy; while a loss of 10 cents per share looks small in one case as compared to \$100 in the other just instanced, the result is the same. A share selling at 15 cents with a par value of \$1, appears to invite a rise of 85 cents, there being a supposition that the nominal rating represents the real worth of the mine when developed; so on the other hand \$99 for a \$100 share appears to suggest the probability of a rise of only one per cent, to par. If the capitalization were in direct ratio, or equivalent to, the value of a mine, such reasoning might do; with things as they are, it is only childish. It is true low prices make for a wider market, but they also mean a less substantial basis of investment, facilitating a panic just as much as they make it easy to create a boom. Not that we deprecate reasonable speculation; mining is essentially a speculation, it is the chance of a large gain that warrants the risk of a big loss. The chief objection to the low-priced share is that it permits of an inflated capitalization; a man is apt to think a ten-cent share cheap, without stopping to consider, for instance, that there are a million of them; the same man will look upon a \$100 share as expensive, even though there be only 5,000 of them. Usually the small denomination is a lure to catch the unwary. Therefore the check to such trading on the New York Curb is not likely to hurt legitimate mining, while it does emphasize once more the urgent need for a respectable mining exchange at the financial centre of the United States.

By the Way.

In a recent issue of the *Electrical Review* there is an excellent editorial on transmission of power by gas, as against electricity. Our contemporary in New York says:

Probably nine persons out of ten if asked what is the best way of transmitting power will say, "by means of electricity," and the tenth person will also give the same reply, unless he happens to be a gas engineer. Until very recently the problem of transmitting power in large quantities over great distances was considered almost purely electrical, and although text-books on power transmission and generation touched upon the possibilities of other means, such as compressed air and gas, these did not receive very much attention. Recently, however, power transmission by means of gas has been under discussion, particularly in England, where the local conditions at London may possibly have had something to do with the respectful consideration the proposal has received. It should be pointed out that these plans do not contemplate abolishing the electric motor. The gas is to be used for transmission only, and not for distribution, for in the latter use the motor is unrivalled. In fact, this fact is recognized by the gas engineers themselves, as is shown by the following quotation from Mr. C. A. Smith, when urging, in the *Electrical Times* (London) for June 21, power transmission by means of gas: "Of recent years a good deal has been said about generating electricity at the pit's mouth and transmitting it to various industrial centres, but it will be considerably cheaper to manufacture producer gas at the pit's mouth and transmit it through pipes to the industrial centres, there to use it in driving gas engines for generating electricity, and also for heating and furnace work. The question of distribution and transmission of power must not be confused. For the former it is agreed that there is no agent to compare with electricity; for the latter purpose it is suggested that it is more economical to employ producer gas and piping than electricity and cables." The emphasis is laid here upon the transmission of the cheapest form of gas, which is not only to bring cheap power to the city, but to do away with smoke.

Transmission by gas, it is true, will solve some of the problems not solved up to the present time by electrical transmission. While all admit that no small motive power can compare with the electric motor, and that electric lamps are the best illuminating agents yet devised, when it comes to heating, the electric system is at a disadvantage. Electrical heaters are perfectly efficient—that is to say, all the energy supplied to them is converted into heat, but the losses which have taken place before the energy reaches the heater are very great, while in the gas system all of the energy of the gas is converted into heat, though all may not be utilized. In other words, we start with our energy in the form of heat, which is obtained by burning the gas. In the electric system we must carry this through a number of transformations, one of which is not very efficient. This disadvantage applies only to electric energy generated from fuel. When obtained from other sources the transformation ratio is high, and the cost depends mainly on the cost of the apparatus.

Since the introduction of electrical power into industrial and commercial life there has been a marvelous development. Methods of communication have been vastly increased; the efficiency of the worker and the electric motor is revolutionizing our methods of applying mechanical power either for transportation or manufacture. It is becoming such an important agent that all water powers have taken on a new significance and are rapidly becoming one of the most coveted of a State's

resources. The utilization of these powers has been by electrical means, and while we have divided this process into parts—generation, transmission and distribution—we have considered these divisions rather from the standpoint of convenience. In this work we have had no rivals, but now the gas man would have us believe that when it comes to transmitting power obtained from fuel that all of our work has been vain and that we must fall back upon other methods. The proposal is interesting, and it will be carefully analyzed; but until further evidence is produced the nine out of ten will still retain their original opinion.

Siberian Concessions.

The Editor:

Sir—In the interests of all parties concerned, the Imperial Russian Consulate at San Francisco hereby begs to communicate to you the following intimation, issued by the Imperial Russian Department of Commerce and Industry.

It has come under the notice of the said department that the 'Northeastern Siberia Company, Ltd.', of St. Petersburg, Russia, whose director in Siberia and America is Mr. John Rosene, 234-235 Pioneer Bldg., Seattle, Washington, offers to all companies or persons desirous of sending prospectors to Cape Chukotski, Eastern Siberia, for mining purposes, to obtain for them the lease of one or more claims, same to be chosen and located by them and to remain in the possession of the lessee, his heirs and legal representatives, successors and assigns, until the mine is exhausted—if they comply with all the conditions of the contract signed with the company. Whereas:

1. According to the Russian mining laws, mining on the Chukotski peninsula and in the whole of the Primorsk province is prohibited to foreigners;

2. Under the contract signed with the Russian Government, the Northeastern Siberia Company, while having the sole right, until 1910, to prospect for minerals and work mines on the Chukotski peninsula east of the rivers Angeionna and Ennenkal, can transmit that right to other persons only by special permission and in its entirety, without parceling the concession into separate claims; and

3. It will be possible for the company, under the general mining laws and under the stipulations of the above-mentioned contract with the Russian Government, to transfer such claims only after the above-mentioned term of exclusive rights in the whole of the peninsula shall have expired and after the allotment to the company of such separate localities which the said company may wish to retain;

Therefore, the Department of Commerce and Industry warns all persons who have already entered or are desirous of entering into agreements with the Northeastern Siberia Company, with a view to leasing claims on the Chukotski peninsula, that the Imperial Russian Government will not admit or recognize the rights of such persons to these claims, although the same be based on agreements or contracts concluded with the above named company.

KOSAKENITCH,
Consul.

Imperial Russian Consulate, San Francisco.

25 July,

— 1906.

7 August.

IN Western Australia carefully conducted experiments proved that on the ore mined there, 2½ in. was the minimum of economy in size in crushing at the breaker, and that any increased efficiency gained in stamping rock of smaller size than 2½ in. was more than offset by the increased cost of smaller breaking at the crusher.

Special Correspondence.

LONDON, July 31.

The latest bid for money in connection with the "revival of a great home industry" is made by the Cornish Tin Properties, Ltd. The capital is £20,000 in shares of £1 each, of which it is said 15,000 have been subscribed for in cash. Nothing daunted by these meagre resources the company expects that its chief immediate profits will be derived from: (1) The advancing of capital on profitable terms for the sinking of trial pits and for exploration and development of properties which have favorable indications or which are considered likely to prove valuable. (2) The advancing of capital on the security of licenses and leases or on a profit-sharing basis for the erection of plant and machinery to those possessed of properties upon which promising lodes have been opened up. (3) The re-sale of licenses, leases and rights as options are acquired from owners, etc. (4) Providing preliminary expenses for the formation of companies to acquire tin mining properties. (5) The brokerage and commission earned by acting as intermediaries between sellers and buyers. (6) The income from investments made in shares, interests, and securities of undertakings (and the re-sale of these) which the directors consider desirable or concerning which the directors may have special information. "In order to secure the earliest possible information of new discoveries and operations and the benefit of local experience, knowledge and practical advice, the directors have constituted an Advisory Committee, consisting of" (more or less) "experienced engineers resident in the centre of the industry." It is easy enough to obtain "licenses, leases and rights as options," and "the sinking of trial pits" is well within the scope of the company, but peddling in shares, even with the advantage of "special information," is a risky business even for a board of directors. While calling in the aid of engineers on the spot for the front page of the prospectus, it is not surprising that this and kindred undertakings should fight shy of the latest report of the Government Inspector of Mines, already noticed briefly in my correspondence of July 4. Regarding the "larger mines" in Cornwall this gentleman refers to them as "for years battling against difficulties and disappointments," mainly owing to the inability in the past to "build up sound financial conditions," now happily possible owing to the high price of tin. With an old-world flavor, in keeping with the conditions of West Country mining, the report in question deprecates the "mere speculative element"—in looking for greater energy and wiser policy in the future development of the industry. Does the Inspector mean 'investors' (who apparently enjoy the smile of his approval) to signify cost-book adventurers, and 'speculators' the shareholders in limited liability companies? If so, he may depend on one thing as certain, that unlike the wise men of old the 'speculators' will be found to remain in the East and will refuse to join the noble but attenuated army of 'adventurers' in the West in continuing a system of mining finance and development, highly suitable no doubt in the time of the Phœnicians but not adapted to the requirements of the twentieth century of the Christian era.

The dividend of 1s. 6d. per share just declared by Dolcoath for the half year (15% per annum) is a latter-day fact which appeals to all who put their money in mines. It is reported that the bottom of the mine is maintaining its value, the average yield of tin per ton from this point being quite 100 lb. and that the increased dividend is not due solely nor chiefly to the improved prices for metal, but to a general improvement throughout the mine and additional capacity of output. At the Tywarnhaile mine

excellent progress is reported in unwatering. The whole of the plant is said to have worked continuously for the past four weeks, during which time the water in the Tywarnhaile section has been lowered to a vertical depth of 95 ft. below the adit. Both the 10 and the 20-fathom levels are now unwatered on the line of lode for a total distance of 2,800 ft. At South Wheal Towan, the water has been lowered 13 ft., and the water-level in Wheal Charles has gone down 18 ft. All of this is considered to show that a large area of country is now being drained and that electric-power pumping has, during the period since starting, been a great and continuous success. It is rumored that Captain William Teague has submitted a scheme to a London syndicate for the unwatering of all the abandoned mines extending from Wheal Busy, in the Chacewater district, to Violet Seton and adjacent mines at Roseworthy, near Camborne. The proposal is to unwater this great stretch of mineralized country by electrically driven pumps, and then commence the driving of a long cross-cut toward the Tehidy Estate. It is a large order, and the man on the spot is not averse to calling in the assistance of the aforesaid men of the East for its accomplishment. At this juncture Cornwall could do very well with a dower such as the late Mr. Beit's benefaction of £1,200,000 in aid of South African railways. Without some such windfall, it is safe to predict that the means available will be inadequate to show any very appreciable increase in the output of tin from Cornwall for the next two or three years.

The eloquence of the chairman at the general meeting of the Spassky Copper Mine Co., in March last, and the inspired press writings about that time have not availed to keep up the price of the shares—then at over £7, now about £2½ less. It may be seen from my correspondence of March 28, that this mine is situated in Siberia, 500 miles from a railway station, and that the smelting works are 72 miles distant by cart-road from the principal producing mine, also that the net profit for the first 15 months, on a share capital of £250,000 with £100,000 of debentures, amounted to £17,000. These facts appeared to justify my opinion that the price of the shares was not warranted by the position and progress of the Company. Subsequent events confirm this view. A circular has just been issued by the directors which states that, owing to the spring floods coming at the time when the new shaft at the colliery was being fitted up, and the old pumps were being replaced by new, it was impossible for a time to raise coal, and the new furnaces could only be supplied with refuse coal, which had been put aside on the surface in former years. In consequence, for two months, copper production was comparatively small. The directors report that they have received most satisfactory assurances of the desire of all leading men in Russia to assist in every way the mining and commercial development of Russia, and particularly Siberia, with the aid of foreign capital, also that "evidences are abundant that it is well known that the vast undeveloped riches of Siberia will soon be one of the most important factors in the future of the Empire." Apparently the directors might have added in all sincerity that "evidences" were also "abundant" that there are people in Europe who would be nothing loath to part with shares in Spassky Copper at a large premium, rather than wait for the development of the "vast riches of Siberia."

The Government's proposals with regard to the new Transvaal constitution made last night in Parliament, are declared to be favorably received by the Kaffir market. If, as seems to be feared in certain quarters, manhood suffrage swamps the British vote, a situation might be created to which mine-owners would not perhaps object. It may be conceded that the huge fortunes built up during

the old Kruger administration would not have been possible under a paramount British administration.

BUTTE, August 11.

The Butte & Superior Copper Co., Ltd., with a capitalization of \$6,000,000, has just been organized in Butte and incorporated under the laws of Arizona by Butte, North Dakota and Michigan men. The company is one of the strongest lately formed to operate in this district; it has purchased from W. A. Clark and associates the Blackrock, Niagara, Raymond and Four Johns mines, and from the Helena & Butte Mining Co. the Jersey Blue, all situated in the North Butte district, a short distance above the properties of the North Butte Co. The consideration for the four mines is nearly \$2,000,000, half of which was paid for the Blackrock, a mine at one time famous as a silver producer and which was involved in the first of the big mining suits tried in the local courts. For several years the Blackrock has been worked under lease by the Blackrock Mining Co., the principal shareholders of which are A. P. Peake, of Valley City, N. D., and John H. Simpson, of Butte, who for 18 months have been working on the organization of the new company, and in acquiring interests in the different properties. In addition to the four developed mines named, the company has also secured the Pardee, Prescott, Paris, Pueblo, Pekin, Paul, Peake and Parker, eight claims situated west of the properties of the Butte Hill and Butte & Bacorn companies north of the city. The Blackrock is opened to a depth of 500 ft., and has been thoroughly developed by Mr. Peake and his associates since they have had possession of it. The Niagara, Raymond and Four Johns have been worked for a long time by lessees and some rich ore is being mined. Some prominent men are interested in the new company, including L. W. Harriman, of Minnewaukan, N. D., and a syndicate of Duluth and Calumet men. W. A. Clark retains a large interest in the company. Among the directors of the Butte & Superior Co. are A. H. Wetthey, general mining manager for W. A. Clark, H. S. Clark of Butte, A. P. Peake, W. D. Clark, several Michigan men yet to be selected, and John H. Simpson, of Butte. Victor Rakowsky, of Duluth, superintendent of exploration of the Zeno Iron Co., spent several weeks in Butte examining the properties for the Michigan syndicate, and it was on his report that the new company was organized. The company owns 4,300 ft. on the strike of the vein, one of the biggest in the Butte district. The Blackrock has been opened by four levels, but there has been no stoping between the 300 and 500-ft. levels. There is also a large quantity of ore still above the 300-ft. level. Lately, driving on the 500 level eastward on the vein into the Four Johns has exposed a good-sized orebody. Assays show 30 to 40 oz. silver and 1 to 3% copper. The ore at one point is galena, assaying 86 oz. silver, an unusual ore in the Butte district. The Blackrock vein is from 50 to 105 ft. wide, and the formation is the same as that of the other mines on the hill. The vein is almost vertical to the 500-ft. level. The Butte & Superior Co. will equip the property with a new hoist and sink the Blackrock shaft to 1,500 ft., with a station every 100 ft. below the 800-ft. level. The old machinery is capable of working to a depth of 1,000 ft. and will be used until the new is installed, when it will be moved to the company's other claims northwest of the city. One of the officers states that with the new machinery it expects to mine from 500 to 1,000 tons per day. When the orebody is opened the upper levels will be turned over to lessees. The last shipment of ore made by the Blackrock Mining Co. averaged about 57 oz. silver, and returned \$30 per ton.

W. A. Clark has purchased all outstanding interests in the Poser, Pilot and Elm Orlu, adjoining the Blackrock

on the west, and will sink a shaft on the Blackrock vein.

—The Pittsburgh & Montana Co. has given a trust deed to all of its mining property in Montana to the Union Trust Co. of Pittsburg, to secure the issue of \$3,000,000 in 6% bonds. The bonds are being issued to raise money with which to pay off an unsecured indebtedness of \$2,600,000, and to provide a fund for exploration and development work. The mines of the company at present are producing about 100 tons of ore per day. It is the intention to sink deeper, and if sufficient ore is found to warrant the company in doing so, its smelters will be rebuilt and enlarged. A statement of the company's financial condition, filed with the Secretary of the State of Montana, shows a capitalization of \$30,000,000, nominal assets of \$30,281,233, and an indebtedness of \$2,600,000. It is stated in the report that the actual value of the assets is but \$7,500,000. The company will shortly put on a third shift at the mines. —The face of the cross-cut being run from the 1,300-ft. level of the Original mine for the Davis-Daly Co. is 125 ft. from the shaft. This company is preparing to sink three shafts and has started work on two of them, and has just received an engine for the third. The company expects to be able to hoist ore from the Silver King and Mt. Moriah shafts in a short time.

TORONTO, August 10.

Forest fires have been raging in the country about Cobalt, especially in the vicinity of Latchford, driving away many prospectors and settlers. The region in the vicinity of Sudbury has also suffered. Heavy rains in the early part of the week brought relief and stopped the devastation in some places. The sanitary conditions of Cobalt camp are still under discussion. The truth of the matter appears to be that while the town itself is fairly healthy, the same cannot be said of all the mining camps of the area, where some sickness prevails, due largely to the hot weather.

The Temiskaming & Northern Ontario Railway Commission has called for fresh tenders for the mining privileges on the right of way of the road through the Cobalt area. The terms provide for a cash bonus of not less than \$50,000, a rental of \$50 per annum, and a royalty on the output at a flat rate of 25% of the value—in place of the sliding scale according to value, objected to by former bidders. The northwest 40 acres of the Cobalt townsite is also offered, the royalty in this case being on a sliding scale of 15 to 50% and the cash bonus not less than \$22,000. —T. W. Gibson, Deputy Minister of Mines of Ontario, has gone on a tour of inspection, including Cobalt, the Gillies timber limit, Sudbury and Sault Ste. Marie.

An American syndicate has purchased several valuable silver properties in the Port Arthur area, including the Silver Mountain, Badger and Beaver mines, which have not been worked for some time. M. A. Meyers, of Mt. Clemens, and Mr. Hanson, of Buffalo, who are largely interested, are directing pumping operations at Silver Mountain, previous to re-opening the mines for active work. —The Eldorado copper mine, in Hastings county, operated by the Medina Gold Mining Co., is giving satisfactory results. The shaft has reached a depth of 220 ft. The first shipment of copper matte will be made shortly from the new smelter.

The gold area around Lake Opastica, Quebec, will shortly be opened up. Sir Thomas Shaughnessy, president of the Canadian Pacific Railway, announced this week that as the result of a conference with Premier Gouin, of Quebec Province, the Canadian Pacific would at once send out surveying parties with a view to constructing a line through the country on the Quebec side of Lake Temiskaming. —Valuable nickel-copper and corundum discoveries are reported near Pontiac, Quebec.

Assays of the former are stated to show 30% nickel and 15% copper, and the corundum percentage is placed at 90. — An order in Council has been passed by the Dominion Government regulating the granting of water-power rights in the Yukon. Such applications may be granted on report of the Government mining engineer to the effect that the water applied for is available and that no other vested interest is affected. A fee is payable as follows: For 50 miner's inches or less, \$10; 50 to 200 in., \$25; from 200 to 1,000 in., \$50; for every additional 1,000 in. or fraction thereof, \$50. Certain amounts must be expended on development within a year and the work is to be completed at a specified date.

A deposit of red hematite ore has been discovered near Dunham, in the southern part of Quebec province. The belt in which this mineral occurs freely is eight miles long and encircles the base of the Little Pinnacle mountain, on the boundary line between Canada and Vermont. Milton Hersey, Dominion analyst, to whom specimens of the ore have been submitted, pronounces it the purest form of hematite of any found in Canada. Options have been secured on all the land around the base of the Little Pinnacle, and blasting operations have been begun by a company headed by Dr. Yates, of Dunham. Drummond McCall & Co., of Montreal, are said to have acquired interests in the deposit.

SALT LAKE, August 12.

The ore and bullion settlements reported by Salt Lake banks for last week aggregated \$552,500, as against \$539,000 the preceding week. The sales of the Salt Lake Stock & Mining Exchange amounted to 162,225 shares for \$94,180.

At the annual election of the Black Diamond Mining Co., operating at Stockton, W. E. Beach, of Lafayette, Ind., was made president; J. R. Rand vice president; Charles W. Miller, Indianapolis, treasurer, and W. C. Alexander, of Salt Lake, secretary and general manager. An amendment to the articles of incorporation making the stock assessable was authorized. — The Honerine mill, at Stockton, is now operating with two shifts and the third will likely be put on about September 1.

Ore shipments from Tintic mining district last week amounted to 135 carloads, or about 6,000 tons, the contributing mines being: Beck Tunnel, 11; Centennial-Eureka, 39; Eureka Hill, 5; May Day, 4; Eagle & Blue Bell, 6; Carisa, 6; Mammoth, 12; Ajax, 4; Victor, 2; Victoria, 7; Grand Central, 8; Scranton, 3; Dragon Iron, 7; Swansea, 2; Bullion-Beck, 6; other mines, 3.

The Utah Development Co., of which Walter C. Orem, of Salt Lake, is manager, will soon be in the market for a mill. This company owns the Red Wing mine, at Bingham, in which some extensive bodies of milling ore have been recently developed. — The Boston Con. and Utah Copper companies, operating at Bingham, are making good headway in removing the overburden from the copper-bearing porphyry. — The management of the Standard Copper Co., of Bingham, has directed the cleaning out of the old adit on the Little Treasure claim. — The management of the Ohio copper mine, at Bingham, has demonstrated that the zone between the All's Well and Last Chance fissures contains commercial ore throughout almost its entire width. Work has been suspended in a cross-cut run through it for 183 ft. It is now planned to commence sinking the projected deep shaft, which is to go 500 ft. deeper than the present lowest level. — The Bingham Metal Mining Co. will make application for patents to 58 lode claims. The new compressor will be started this week and the main adit continued into the mountain. The plant will be operated by water-power and has capacity for five drills. The company has expended \$25,000 in development and equipment during the past year. The claims are partly on the Bingham

and partly on the Tooele county side of the Oquirrh range. Supplies are taken up to the mine from Tooele. The Utah agent of the company is H. A. Smith, McCormick block, Salt Lake.

The Utah & Eastern Copper Co., operating in Washington county, is working 150 men, and a traction engine and four four-horse teams handle the company's traffic between the mine and railroad. The smelter is running and 200,000 lb. of copper matte have accumulated pending the repair of roads recently destroyed by washouts. The three-compartment shaft which intersects the main working adit on the 600 level is down nearly 1,100 feet.

Ore shipments from Park City last week aggregated 2,012 tons, the Silver King contributing 620; Daly-West, 475; Daly-Judge, 653; Kearns-Keith, 53; Little Bell, 211. — The July output of the Little Bell mine, at Park City, was 915 dry tons, for which the company received a net profit of \$45,008. A compressor is being installed. — The Daly-Judge Mining Co., at Park City, has made a net profit of \$45,000 monthly since January 1 last. The mine is in excellent condition and there is nearly \$100,000 in the treasury.

A deal was consummated in Salt Lake this week which places David Keith and Thomas Kearns in control of the Ely Mining & Milling Co., which owns 13 claims at Ely, Nevada. At the same time the purchase of the Maceo group, an adjoining property, was effected. Altogether about 400 acres have been acquired. Keith & Kearns have also secured control of the Success property in the Duck Creek district, 13 miles east of Ely.

The management of the Majestic copper properties, in Beaver county, reports that a large body of silver-lead ore has been exposed in the Gomer shaft of the Harrington & Hickory, which is a lead-silver mine, though at water-level copper makes its appearance.

The Continental Mines & Smelters Corporation, of which Henry M. Crowther, of Salt Lake, is manager, has decided to provide additional equipment for its aerial tramway now operating between the Continental-Alta mine and mill, five miles below, which will enable the management to handle the present output of other mines in the camp. Alta operators have suffered greatly because of scarcity of teams. By using the tramway, the situation will be materially improved.

CRIPPLE CREEK, August 13.

It is rumored that the Vindicator Gold Mining Co., whose property is situated on Bull hill, will follow the example of the Isabella Co. and begin the erection of a mill to treat the low-grade ore in the mine and on the dumps. A site near the town of Independence is said to have been decided upon, and the erection of the mill is to take place without delay. — A clean-up was made last week by the Ironclad cyanide mill on Ironclad hill, resulting in a gold brick valued at \$2,700; this was obtained from the treatment, at a profit, of ore running about \$3 per ton, which is a very good showing indeed. — Work on the new cyanide mill of the Isabella Co. is progressing rapidly; the excavating has been completed and 27,000 ft. of lumber have been used for supports and flooring. The size of the tank-building will be 190 by 34 ft., the tank capacity being 750 tons. The ore is expected to be treated at a cost of \$1 per ton.

The Mary Alice claim on Battle mountain, situated between the Stratton's Independence and Portland properties, is being extensively worked by the Monument Gold Mining Co., of which Mr. Woodward is treasurer and general manager. A cross-cut is being driven at the 200-ft. level to intersect an orebody cut on the 400-ft. level below. At this depth the vein was not of sufficient grade to be worth extracting, but it is hoped that when it is cut at a less depth it may be of better grade.

Rich ore is being shipped by the Curry lease on the Lucky Gus of the Stratton Estate on Bull hill. On the 600-ft. level a rich mud streak, which is only two to three inches wide, is being followed. A car of ore was shipped from this place last week giving returns of between six and seven ounces in gold per ton. A small washer has been installed in the ore-house, which is used to wash the mud from the rock, making sorting more efficient. —The two big hauling companies of the district have been consolidated, the Cripple Creek Coal & Transportation Co. being taken over by the Colorado Trading & Transfer Co. A good deal of ore-hauling is being done from the smaller properties to the railroad, and this work will now be done almost entirely by the Trading Company.

The American Eagles mine of the Stratton Estate on Bull hill, until recently under lease to Cox & Durbin, has been started up again by the Western Investment Co. The mine is being prospected on the various levels by this leasing company, which intends to take it over shortly under lease from the Stratton Estate.

The production of the Golden Cycle mine for July was in the neighborhood of 5,500 tons, which places it among the largest producers of the camp.—A strike of rich ore has just been made on the Henry Adney mine on Beacon hill. A shipment was made on the 11th inst., which is expected to give returns of about ten ounces. This find was made on the 600-ft. level, and 200 ft. north of the shaft, where a cross-cut has been driven to intersect the orebody discovered some time back on the 500-ft. level. The actual altitude at which this ore has been discovered is the lowest known working in the district, and the find is said to be the richest that has been opened up for many months.

COBALT, August 12.

Northern 'New Ontario' and northern Quebec are known to possess important mineral deposits and the reported gold discoveries in the latter Province, near Lake Opastica, excited no surprise. When the two Frenchmen, Renaud and Ollier, came into Cobalt camp in June, bringing rich gold samples and telling their story, their statements were readily believed by even the most conservative. There was a rapid rush to the city of Quebec by men with money, and, as the mining laws of Quebec are liberal, many hundred square miles were applied for. The Government of that Province leases land at \$5 per square mile for three months for the purpose of prospecting, the lease being renewable as often as the lessee desires to pay the rental. Within a week after the two prospectors mentioned had reached Quebec, 200,000 acres had been applied for, the rental paid, and leases issued. Then began the rush to the promised land. The new discovery was supposed to exist near Lake Opastica, 140 miles north of Mattawa, which is on the main line of the Canadian Pacific railway, and 65 miles north of the town of Cobalt, on the Temiskaming & Northern Ontario line. Leaving the main line of the former railway, a branch, known as the Keepawa, runs north 40 miles to Lumssden's Mills, a lumber town at the foot of Lake Temiskaming. The railway skirts the Quebec side of the Ottawa river, which, for the entire distance, is interrupted by chutes, rapids, cascades, and waterfalls. At the Mills a steamboat company has two large boats running up and down the lake.

The Temiskaming & Northern Ontario railway, built and owned by the Province of Ontario, affords another means of access to this northland. It runs from North Bay to Lake Abitibi, where it will cross the transcontinental railway now under construction, its ultimate terminus being Hudson bay. It touches Lake Temiskaming at Haileybury, so that the traveler can take the boat at

Temiskaming and come up the lake to the French Canadian village of Ville Marie, or he can take a boat at Haileybury and go down the lake to this village, and proceeding by a good traveled road, reach the foot of Quinze lake and thence by canoe proceed through a chain of lakes to Opastica. If a steamboat trip is preferred for the entire length of Lake Temiskaming, it can be taken to North Temiskaming, and it was from the northern end of the lake that the writer's party made its start. After a 16-mile tramp over the most abominable road that even 'New Ontario' and 'New Quebec' can offer to the adventurous seeker of riches in these remote districts, we arrived at the landing known as Klock's, a well-tilled farm of 200 acres, with good buildings and stock. A thriving business has been done by these northern agricultural pioneers this summer in supplying the wants of the army of prospectors going into and beyond the 'height of land.' From Klock's the ordinary prospector goes by canoe and a three days' paddle follows; but finding an easier mode of travel, we took passage on a boat, which plies these northern lakes, and is of a species unknown to most boat-builders. A queer sort of craft it is. Were it possessed of life it might be termed batrachian. It is, however, by no means inanimate, and is termed an 'alligator' boat, because it travels by land as well as by water. It is simply a fair-sized scow with paddle-wheels and a haulage-engine, generally used in the lumber country in towing logs. It has a cable and anchor. The anchor is snubbed to a tree and the boat pulls itself along in this way and is capable of crawling over any portage. Quinze lake (called Cass lake by the natives) is 25 miles long, and our boat maintained a speed of seven miles per hour. At the end of the lake came the entrance to Lonely river, up which we ran to the first portage which brought us to a small lake called Obicobo, or Barrier; passing this we traversed another branch of Lonely river for a few miles, which brought us to Opastica lake, at the end of which we pass the 'height of land' (divide). Here we come to height-of-land portage and five miles north of this, on Fortune lake, and 40 miles north of the head of Lake Temiskaming, we found the spot where the great gold discoveries were supposed to have been made.

Once again we found searching for gold as disappointing in the realization, as it had been alluring in anticipation, on the journey up. We found nothing in this particular part of northern New Quebec but a belt of schist in which is a 'blow-out' of quartz, showing no vein-structure whatever, merely a segregation of silica in the schist. The formation consists of quartzite, slate, conglomerate, and schist, of the Middle Huronian, and they show no evidence of disturbance, or igneous intrusion such as would tend to concentrate orebodies. The samples brought down by the original prospectors were never found in this part of the country. Scattered through the adjacent district, and for a radius of 30 square miles, we left possibly 100 prospectors at work, and if any valuable minerals exist there, they will undoubtedly be found before fall.

Crossing into the Province of Ontario, we paddled down to the township of Boston, where we found several men at work. Several promising locations have been staked out. The mining laws here are very different from those of Quebec. The first discoverer plants his discovery post and blazes a trail to the northeast corner of his location, and then goes to the Mining Commissioner and files his application and affidavits of discovery. He then has to go to work on his property, and get it ready for Government inspection. Having passed inspection, he retains his property by doing the required development work. At Boston, two locations have been staked out, one known

as the Grigg, or Mosse-Horn, and the other as the Miller prospect. At the former they have an eight-foot vein of red and white quartz exposed for 300 ft. Gold and silver traces appear 'shot' in the wall-rock, but the result of assays has not yet been received. Several samples have been sent down to the nearest assay-office. Meanwhile the locators have several men at work. Further south, in the Wendigo lake country, it is known that there are several propositions being worked both for gold and silver. There are millions of acres in this northland awaiting the prospector. Here already are many adventurous prospectors, lost in the immensity of the country. There is no railroad as yet, but the entrance of the trans-continental road, and the Temiskaming & Northern Ontario, will afford easy access. With a line running in either direction affording bases of supplies, the natural water-ways will enable the seeker after mineral wealth to enter many regions hitherto unexplored, except by the Indian and an occasional trapper.

At Cobalt many new discoveries are being made, outside of what has hitherto been known as the camp proper. Both up the Montreal river (at Portage Bay), and down three miles from the Kerr and Cross Lake properties, rich finds have been made, which are enlarging the known area of the mineral-bearing zone. Down in Lorrain good finds are being made and the future of the camp is assured. Many expect the output for 1907 will exceed that of any silver camp on the continent. A display of the ores of the Cobalt district will be made at the annual exhibition which opens at Toronto August 27, lasting until September 8. This is the largest annual exhibition in the British Empire. The attendance last year was over 600,000, and the exhibit of ores will include nuggets from all the working and shipping mines.

JOHANNESBURG, July 16.

Why is it that with record outputs, the depression in the Transvaal continues? This is the question heard on all sides. It does seem extraordinary that with a gold production for June worth well over £2,000,000 there should be such a condition of affairs in the Transvaal. Men who have grown gray in the country declare they have never seen a worse state of affairs than exists at present. The suffering and distress in Johannesburg is probably as acute today as it has ever been. The charitable institutions have all they can do. Appeals are made to the public for donations of all sorts. And this in spite of a monthly output of over £2,000,000. The irony of it!

The cause? The feeling of uncertainty that exists all over the country. No one knows what the morrow will bring forth. The Liberal Government has generally brought a blight to South Africa, and the Liberals are in power today and rampant. Their latest move has caused more uncertainty than ever. As is well known, the Liberal Government some time ago caused a poster to be placed in the Chinese compounds, offering the dissatisfied coolies a passage to China. Out of 50,000 coolies about 50 asked to go back. This was a splendid refutation of the lies about slavery and discontent promulgated by the Liberals.

In a spirit of pique, they have signified their determination of putting up yet another poster. The inducements offered the coolies to break their three years' contracts will be most favorable. By contributing a fortnight's pay to his passage money, the coolie will be able to get a trip to China. How will the coolie receive this new poster? It is nearly impossible to prophesy what a Chinaman will do at any time. I am of the opinion, however, that the effect of the new poster will be nearly as contemptible as that of the first. It is now proved beyond the question of a doubt that the coolies

are contented with their treatment on the Rand, and are happy here. They begin to realize that the Party at Home are trying to oust them out of the country. When the new poster is stuck up, I predict that the vast majority of the coolies will read it, and then utter the Chinese oaths of disgust. Of course, there will be some of the discontented coolies (generally the 'wasters,') of whom there are 50 or 100 on every mine, who will take advantage of the offer to return to China.

What with the Liberal Party, and the coming political struggle in the Transvaal, the feeling of uncertainty is very acute. Could people know for certain that the country would have peace, that the present excellent results would steadily continue in the future, that ample labor would be forthcoming, then the present depression would vanish in a day. It is because people realize that a large number of the mines will be seriously crippled, if not closed down altogether, by the policies advocated by those in power, and those likely to be in power in the future, that the feeling of apprehension is so great. Once take all the coolies away and try to force white labor onto the mines and you close down the gold producers of the Rand, save the remarkably rich mines of the Central Rand, like the Robinson and Ferreira. The burden of taxation that the mining industry has to bear is very heavy. If half of the mines are closed down the burden on the producing mines will be increased.

The celebrated anti-Chinese Mr. Creswell has opened the campaign against Chinese labor anew. In a speech the other night he referred to the Chinese question as a huge political fraud. Another anti-Chinese advocate opened a campaign against the coolies in Pretoria. These gentlemen are at least earnest, and have not used the absurd slavery cry, which caught so many votes in the recent political struggle in England. Mr. Creswell, while manager of the leading mine, tried white labor extensively, and firmly believes he made it a success. An impartial committee appointed to investigate the matter differed entirely from Mr. Creswell. This gentleman still maintains that white labor would be as economical as coolie or Kaffir labor. But as he is the only mining man of importance in the Transvaal who believes in the doctrine of white labor, the man in the street places his faith in the verdict of the majority.

ROSSLAND, August 12.

Following is the tonnage shipped from and crushed at the mines of Rossland for the week ending August 11: Centre Star, 1,680 tons; Le Roi, 2,610; Le Roi Two, 480. Total, 4,770 tons. Total for the year, 194,399 tons.

At the Trail smelter the work of enlarging the equipment of the Consolidated Mining & Smelting Co. is proceeding steadily. For the week ending Friday, August 10, the following shipments of ore were received besides those sent from Rossland: Snowshoe, Boundary, 409 tons; Iron Mask, Kamloops, 195 tons; St. Eugene, Moyie, 119 tons; North Star, East Kootenay, 109 tons; Providence, Boundary, 65 tons; Snowstorm, Idaho, 26 tons; Lone Bachelor, Slocan, 21 tons.

Boundary ore shipments for the week were as follows: To Granby smelter, from Granby mines, 18,048 tons; Emma mine, 133 tons. To Dominion Copper Co. smelter from Brooklyn-Stemwinder, 2,704 tons; Rawhide, 367; Sunset, 644; Mountain Rose, 39. To Trail smelter, from Providence, 30 tons. To Nelson smelter, from Emma, 330 tons. Total shipments for week, 22,475 tons; total shipments for year to date, 753,150 tons. Boundary smelters this week treated as follows: Granby smelter, 18,250 tons; Dominion Copper Co.'s smelter, 3,754 tons; total treatment to date, 750,354 tons.

Mining Summary.

ARIZONA.

COCHISE COUNTY.

The vein on the Mayflower, John A. Duncan's property two miles southwest of Paradise, has been cut in the adit and is three feet wide. The breast of the adit is more than 400 ft. from the portal. The vein runs in an east-west direction. This strike, which is made on property adjoining the Chiricahua, is one of the best made in the history of the camp and is of much importance.—At the Uncle Sam, owned by Gallen & Warnekros, of Tombstone, operations continue in the adit which has been driven 60 ft. Copper sulphide has been encountered.—On the Bernoudy property, W. P. Wright, one of the owners, is working in the adit on the Elizabeth, the scene of the rich strike.

GRAHAM COUNTY.

(Special Correspondence).—The Arizona Copper Co., at the Longfellow mine, has just completed a 1,300-ft. adit which connects with a 600-ft. shaft, at the top of which is now in course of construction a shaft-house in which is to be installed a hoisting plant. The ore will be dumped into the receiving bins of No. 5 concentrator. In this way three miles of haulage, over steep grades, will be avoided. At the Longfellow surface incline, of this company, to which over 600 ft. has been added at the upper end, bringing it to the same level as the Humboldt, Joy and Clay mines and the No. 5 and 6 concentrators, a winding-drum, 11 ft. diam., has been installed, and engine-house erected, and a new 30-h.p. gasoline engine put in. The old machinery, including brake, engine and drum, have been transferred to the head of the Coronado incline, of this company. On the site of the old boarding-house, there will be erected a 400-h.p. ventilating plant for use in the surrounding mines of this company. Power will be furnished by two 200-h.p. Stirling boilers, the machinery being already on the ground. Since concentrator No. 6, of the Arizona Copper Co., at Longfellow, has commenced operation, it has been found that the storage-ore-bins are too small. Following any stoppage at the crushing plant, the mill is compelled to shut down, owing to lack of ore. It is expected that bins of quadruple capacity will replace those now in use. At the mill recently completed by the Detroit Copper Co., an entirely different plan was followed. The crushed-ore-bins have capacity to hold ore enough to run 12 hours, the crushing plant running only during the day, which arrangement has given satisfaction. At the top of the Joy shaft, on the Humboldt level, the Arizona Copper Co. has completed the foundations for two large ore-bins. The ore cars will run directly from the hoisting cages over the bins from which the ore will be loaded directly into the train.—The hoisting plant of the Shannon Copper Co., at the top of their incline, which was recently entirely destroyed by fire, has been repaired, and is now running full time.—The recent heavy rains caused a large boulder to fall on and break the pipe connecting the Detroit Copper Co. reduction works with their water supply (the Gila river), and caused a few hours shut down. Morenci, August 11.

CALIFORNIA.

ALPINE COUNTY.

The village of Loope is excited over a find made recently in the Hercules mine, owned by Reno people. In driving an adit to cross-cut the vein an eight-foot vein, previously unknown, and rich in gold and silver, was found at a depth of several hundred feet. The mine was formerly owned by Peter Curtz and was sold several months ago for \$100,000. In a few weeks the new company will begin crushing 150 tons daily. As soon as the machinery can be received an electric plant will be installed.

DEL NORTE COUNTY.

(Special Correspondence).—Two companies have lately been formed by local parties. The first, of which D. W. Rice is president, and G. W. Manley is secretary, is to be known as the California & Oregon Assaying & Mining Co. The first object of this company is to maintain a complete assay outfit under competent man-

agement, to be of assistance to miners and prospectors in determining the value of their property. Mr. Marlowe, of Haynes Flat and the Doctor Rock, has been active in interesting the business and professional men of Crescent City in this venture, and enough stock has been placed to insure a good start. The outfit has been ordered and arrangements are being made for commencing operations immediately upon its arrival.—W. H. H. McCutcheon, of Myrtle Creek, has induced local parties to form a corporate company for the purpose of carrying on hydraulic operations on Myrtle Creek, which has produced a large amount of gold. The gold in this creek is mostly heavy, nuggets weighing from \$2.50 to \$40 being not uncommon. One piece, taken out some years ago, weighed \$900. The company has engaged John D. Platts to assist in opening and operating the property. Mr. Platts is now making surveys for the hydraulicking plant and the company is preparing to commence work as soon as the surveys are completed.

Crescent City, August 11.

Baker Bros., of Spokane, are driving an adit on their cinnabar mine on Brushy ridge. It is in 250 ft. on ore. This is a low-grade but large property. It has long been known that on Diamond creek, in the northeastern portion of this county, were deposits of cinnabar, but no extensive work has ever been done. Mr. Laey, of Chicago, has engineers on his Cleopatra copper mines in the Diamond creek district surveying, preparatory to doing annual assessment work. Some rich specimens of copper ore have been taken from the Cleopatra.

INYO COUNTY.

(Special Correspondence).—The Terry Mining Co. is operating a group of promising claims six miles south of Ballarat, where development work has been in progress for more than a year. Good ore was struck at a depth of 50 ft. At the 100-ft. level a cross-cut was driven 130 ft. in quartzite, which assays 83 per ton gold. At the end of this a 50-ft. vein was cut which contains a much better grade of ore, some of it going \$10 per ton. This so-called vein is really a dike intersecting the quartzite which is the country rock here. At 400 ft. below the outcrop an adit has been run 600 ft. to again cut this dike. In this adit, 400 ft. in, a 30-ft. vein of good ore was cut. It is thought that the main vein will be reached at 700 ft. There are several smaller veins two to three feet wide intersected by this adit, some of which carry good ore. A mill test is being made on ore from these mines to determine the character of mill and treatment required. A tramway and mill are to be built.

Ballarat, August 9.

(Special Correspondence).—This camp looks good. That is, a great many are expected in here this fall. People have been coming in pretty lively for the last few weeks, but the scarcity of water keeps a good many out at present. Water is now hauled 28 miles from Furnace creek, and is sold by the gallon.

Greenwater, August 11.

The Cuso Reduction Co. is concentrating and shipping slag from the old Deliance dump near Darwin. The same company controls the Lucky Jim slag piles. The total amount available for re-working is estimated at 16,000 tons.—The Garvin Mining & Milling Co., which lately bought the '98 gold mine at Cuso, has suspended operations pending the erection of a reduction plant.—J. L. Giroux, after an examination of Chas. Richardson's claims at Darwin, bought them. The company, in which he is the principal stockholder, is known as the Rio Tinto Co. and is opening a claim by that name. On this mine an 82-ft. shaft had been sunk. With the idea of making it two compartments, another shaft was started beside it. Though the first showed little or no ore, the new part is in ore all the way down; the first miners having just missed it. Twelve men are employed.

MODOC COUNTY.

What will be the first quartz mill in Modoc county is on its way from the East. J. M. Layman, manager of the Mines Venture Syndicate, at Fort Bidwell, has made arrangements for the machinery. This company is interested in the newly discovered mining district near Fort Bidwell.

NEVADA COUNTY.

(Special Correspondence).—At the Republic mine, at Graniteville, grading for a 20-stamp mill is in progress and 10 stamps of the mill are on the ground and will be placed at once. The vein is from 10 to 20 ft. thick and is good milling ore. A main adit is being driven, which will make available 400 ft. of backs. Water under a 480-ft. head is the motive power.

Graniteville, August 11.

After more than a year of development work, the adit on the property of the Richard Gold Mining Co. has penetrated the rim of the Manzanita gravel channel, near Nevada City and it is expected gravel will be struck any day. The character of the bedrock has changed materially in the past few days, and the heavy flow of water indicates the proximity of the ancient river bed. This company owns over 7,000 ft. of the channel on Cement hill. Several stockholders from Mansfield, Ohio, recently visited Nevada City.

SHASTA COUNTY.

A 200-ton shipment of copper ore from the Hornet mine, near the Iron Mountain, has been made to Martinez, where the Mountain Copper Co. will work it in the smelter as a test. It is stated that if the test is satisfactory a branch railroad will be run from the company's railroad at Boulder creek to the Hornet mine. The ore was transported on eleven packhorses.

SIERRA COUNTY.

John Hayes, of Sierra City, has bought from J. W. Finney the 20-stamp mill at the Sierra mine on the East Fork, two miles above Downieville. It will be removed to the King Con. mine, near the Marguerite, a short distance below Loganville. This mine is owned by Hayes and others and considerable development has been done on the property, and the owners now feel justified in putting up the mill. The lower adit is in 500 ft. on the vein, and they have about 500 ft. of backs. The vein is five to six feet in width and prospects well.—A rich strike is reported at El Dorado quartz mine on Kanaka creek, near Alleghany. This mine, which has been worked for years, was formerly owned by B. B. Lewis and J. Fessler, and about \$75,000 extracted near the surface. Since then a lower adit was run. A few months ago H. L. Johnson, of the Tightner mine, took a bond on the property and put men at work extending this adit and soon struck the pay-shoot.

SISKIYOU COUNTY.

A. C. Brokaw and associates several months ago bonded the Golden Eagle mine to W. P. Hammon of Oroville for \$120,000. The bond expired by limitation, the parties failing to agree on the amount of the cash payment. Since then they have uncovered a pay-shoot, and the ore now in sight is said to be worth \$300,000.

During the month of July there were filed in the recorder's office mining location notices covering 9,000 acres. A large proportion of the locations made were on copper prospects.

TUOLUMNE COUNTY.

(Special Correspondence).—The new 5-stamp mill on the McDonnell Ranch mine, south of Jamestown, has been started and the results are said to be satisfactory.—Wm. Sharwood has deeded his half interest in the Keltz mine and millsite, Kelvin mine and millsite, north extension of the Keltz mine, and Keltz ditch, 10 miles north of Soulsbyville, to Dudley Baldwin, of Cleveland, Ohio. A half interest in the same properties, and in the Dagmar and Alexander quartz claims, was sold at the same time by Arthur L. Huston to H. L. Huston.—Work is being done on the copper claims owned by Herbert Shaw, J. B. Curtin and others, situated near the summit of the Sierra Nevada in this county, and it is reported that high-grade ore is being found. The discovery of copper in that region was made by Mr. Shaw a year ago, when a large number of claims were located.—It is reported that in the Jumper mine, near Stent, encouraging prospects are being found in the winze being sunk from the 1,400-ft. level.—The rich strike reported made in the Jumper mine some weeks ago was without foundation.

Tuolumne, August 13.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The present activity in mining in Georgetown district exceeds that of any time since 1893. Although the district has always held its own as a producer of high-grade ore, little, if any, outside capital has been invested here until this year. This can, to some extent, be accounted for by the good price now obtainable for zinc and lead ores, many of the old properties here containing large bodies of this class of mineral, which it did not previously pay to mine. The great improvement in the methods of concentration and separation of ore is also a large factor in the increased activity, as the material in the great dumps and the waste in many old stopes can now be treated at such profit that many old mines are again being made to pay handsomely.

There was an increase of 100% in June over May in the amount of ore shipped to the sampling works. The Independent sampling works and concentrating mill of the Santiago Co. are handling several hundred tons of ore monthly, and are far behind with the concentrating ore, the bins all being full and many tons piled outside the mill. This company is paying 11c. more per unit for lead than the smelter trust pays.

The Waldorf Co. shipped 600 tons of ore during July, some of which was concentrate, from its mill at Wilcox, East Argentine.—The X-Ray Co., which is working the Doric, Magnet, and Comet groups through the old Doric adit, closed down since 1900, has opened a fine body of concentrating ore on the Cram lode 2,400 ft. in from the portal. At 2,800 ft. in, stoping has been commenced on a streak of smelting ore; the adit is now in 3,009 ft., and will be driven ahead to cut the Comet vein, 2,000 ft. distant.—Resumption of work by the Democrat Mountain Mining & Milling Co., on the old Kelly Tunnel property, is of interest. The company has let a contract for a concentrating mill of 50 tons daily capacity. A tramway 2,000 ft. long is to be built from the mill to the Moline adit. A raise is being put up from the adit level, 220 ft., to the Boston level, where large bodies of lead and zinc ore are blocked out said to be worth \$16 per ton. Sufficient ore to keep the mill running two years is in sight.

The Griffith Mines Co., owner of the East Griffith mine, which was the first location in the district, has let a contract for a mill similar to that of the Democrat Mountain Co. There are large bodies of lead ore containing silver, zinc, and copper, opened up in the extensive old workings. This property has been idle for five years.

Georgetown, August 11.

DOLORES COUNTY.

The principal orebody underlying the town of Rico is being mined from under its streets and alleys through the Atlantic Cable shaft by the United Mines Co., from another portion of the company's property, the Black Hawk group; shipments are being made under contract to Colorado smelters, and also to the Missouri and Kansas zinc smelters. From another part of this property, the Grand View, high-grade zinc sulphide is being mined.

LAKE COUNTY.

In South Evans gulch, Leadville, with few exceptions, all the mines are shipping. The rich ore lately encountered in the Winnie holds out; it has now been opened for over 200 ft. and the ore assays the entire length from 50 to 56 oz. per ton. The Enterprise people are driving on the 200-ft. level, but have not yet found the ore. The Silver Nugget shaft has been unwatered, and is being sunk. On the Gnome ground, adjoining the Izzard, work has begun. At the Ella steady shipments of 50 tons daily are being sent to the smelter. The ore is sulphide carrying gold. The lessees on the St. Louis are also shipping steadily, the ore running \$30 per ton.—The refusal of the Pueblo smelters to buy more manganese ore before October 1, is working a hardship on some lessees who were sending out that class of ore.—The Morning and Evening Star, on Carbonate hill, continue to output about 400 tons daily of argentiferous iron and some lead carbonates. Not a shaft belonging to the consolidation is idle. John Lynch is sinking a new shaft near the

old Morning Star and is down 65 ft. He expects to go about 150 ft. before driving to the orebody. Nels Lind is employing eight men and is driving from the 400-ft. level and shipping 100 tons per week.—Sixteen men are at work on the upper Waterloo shaft and taking out a car of ore daily while prospecting.—Recent development in the Helena, on Iowa gulch, shows that the ore carries 2 oz. gold per ton, in addition to the silver and lead. It is unusual to find gold in such quantities in this part of the gulch. The work on the new orebody is being pushed and Mr. Brenneman, the manager, thinks he has caught the main ore-shoot.

SUMMIT COUNTY.

(Special Correspondence).—Frisco is unusually active just now; not only the new but also the old companies, which have for some time been indifferent in their operation, are hustling and making the camp lively.—The King Solomon is operating and steadily pushing the main adit into Mt. Royal with machine-drills. The management is securing more territory, including some well situated ground on Miner's creek. The surveyors have just completed their field work.—The Mint Mining & Milling Co., operating in Ophir mountain, is working two shifts. The adit recently passed through a good vein.—Heckman's Eureka, situated below the Victoria mine on Royal mountain, has produced some rich float, which has ranged as high as \$3,700 per ton gold. An adit 260 ft. long has been run through the surface debris by the owners, Heckman & Linquist, and they are now coming into solid schist, the characteristic formation of the mountain.—The property on the east of the Victoria, which latter was worked for a long time by Albert Newton, has been taken over by a Denver company, with Mr. Colburn at the head of affairs.—The Square Deal has established a model camp at the foot of Chief mountain, on the North Ten-Mile canyon. A good water supply is piped from a nearby gulch, all through the camp, for domestic and fire purposes. Work is confined to driving the main adit, which is now in 125 ft. The Mary Verna Co.'s main adit is in 1,105 ft. and the formation is changing for the better, a sprinkling of copper and iron pyrites showing in the rock.—The North American has its main adit in 1,300 ft. headed for a point beneath the apex of Peak 1. The work is now approaching the Michigan vein.—The Boltz property, on Peak 1, has been signed over, under bond and lease, to the Southwestern Brokerage & Investment Co., of Memphis, Tennessee.—Martin Hartman, an old-time prospector and miner of Summit county, has located some claims on Slate creek, 20 miles below Dillon. He claims to have an outcrop several feet wide, carrying from \$5 to \$12 per ton gold and 50 oz. silver, and the rock is heavy in iron sulphide.—The placer mining operations at Breckenridge are giving excellent returns. The water supply is still adequate, the unusual intermittent rains having aided greatly.—The Colorado Consolidated Mining & Exploration Co. has been sluicing in the vicinity of the Gold Pan pit, in the Blue river, and its first clean-up for this season exceeded expectations.—The Mecca Co.'s ground-sluice is fast approaching the old Oro Grande pit and the work is now on bedrock.—At the Summit Banner, in Iowa gulch, sluicing continues to uncover boulders of rich gold-bearing quartzite. This property, it is thought, may develop into a lode-mining property.—The Reliance Dredging Co., in cleaning up the Reliance dredge lately, found a large piece of zinc ore carrying free gold.—The old Union Co. has completed its connection by raise from the main adit to the old workings, and 85 ft. of it is on a 5-ft. vein of concentrating ore. The Gold Dust-Puzzle combination is now being worked. The electric pump and hoist have been installed and are driven by power from the Colorado Consolidated Mining & Milling Co.'s works, at Breckenridge. The Blue Flag, now operating the Laurium mine on Bald mountain, has completed the addition to its mill. J. F. Elisman, president of the company, was up from Denver last week looking over the property.—The Bay State Mining Co. is operating on North Star mountain under management of Arthur Howard. A strike of high-grade copper-gold ore was made last week. The ore assays \$150 per ton. A new lower adit is being started.—The Nebraska Co. is a new corporation formed by B. B. Green and others, of Nebraska, and is operating a group of claims on the east

side of the North Star mountain, not far from the Atlantic mine. At the Atlantic, regular shipments of high-grade gold ore are being made to the Denver smelters.

Breckenridge, August 11.

IDAHO.

LEMHI COUNTY.

It is reported from Prairie basin that a Placer miner, Eli Minert, has traced cassiterite float up Big creek to its head and has found dikes containing tinstone in place. The float was followed more than three miles.—E. M. Burton reports a big strike of gold made on the Wahn property on War Eagle mountain.

WASHINGTON COUNTY.

A. Griswold says gold-bearing ore has recently been found in a mine of the Goodenough Mining & Milling Co. at Marshall lake. A five-stamp mill is now being installed.

MONTANA.

LEWIS AND CLARK COUNTY.

The Circuit Court of Appeals has affirmed the judgment of the Federal Court in the case of the St. Louis Mining Co. against the Montana Mining & Milling Co. (Drum Lummon mine at Marysville). The lower court gave the plaintiff a verdict of \$195,000, the value of ore extracted from the vein in dispute. The costs of the suit will bring the sum up to \$223,000, which the Montana Mining & Milling Co. must pay. The verdict is said to be the largest ever obtained in a court in Montana.

NEVADA.

CHURCHILL COUNTY.

As soon as the best method of treating the ores of Eastgate has been determined several of the operators of that camp propose to erect a suitable mill. This plant will probably be the first to be built in the new camps of this county.

DOUGLAS COUNTY.

It is reported at Carson that the Mammoth mine, 25 miles south of that city, in the lower portion of the Pinenut range, is to be developed by the Alaska-Treadwell Mining Co., which recently purchased it from F. B. Livingston. The company has completed its plans, and a large electric generating-station will be built with which to operate a stamp-mill. The ore in the Mammoth is low grade. Already a large amount has been blocked out. Several hundred men will be employed.

LINCOLN COUNTY.

(Special Correspondence).—An effort is being made to organize a board of trade in Searchlight.—The Searchlight Co., of San Bernardino, has purchased the Confidence claims from A. L. Heydloff and A. H. Smith. It is reported that, following up a recent strike on the Confidence, ore that runs \$70 per ton is being mined.—The recent consolidation of the Providence Exploration Co. and the Juniper and Chiquita groups, situated in this district, under the name of the Chiquita Con. Mining Co., brings together over 50 claims, with an aggregate area of about 1,000 acres. E. J. Knight is president and general manager; Everard Holmes, secretary; and H. S. Peck, treasurer; with headquarters at Searchlight. Arrangements are being made for the purchase of machinery. A short time ago a strike was made on the Chiquita group, from which shipments of high-grade ore are now being made to the Needles smelter.—Edward Carleson, of the Wyoming-Searchlight, has returned from Salt Lake City, where he organized a company and secured capital to proceed with the development of the property. The shaft is now down 200 ft. Contracts have been let for surface improvements, and the shaft will be straightened and re-timbered.—George Bergman has sold the Georgia Con. group to H. J. Dull, of Los Angeles, for \$50,000, of which \$5,000 was paid down. This property consists of eight claims, situated in El Dorado canyon one mile east of the Techaticup. Little development work has been done, although Mr. Bergman states that the examining engineers took 114 samples which assayed an average of \$14 per ton gold and silver. Water for camp purposes has been developed at a depth of 15 ft.—In cutting a hitch in the hanging wall of the Venus shaft, the rock was found to be ore, and further investigation disclosed 16 in. of high-grade ore entirely outside of the line of the shaft. The shaft is all in

ore and the vein is widening with depth. Recent assays taken from the bottom averaged nearly \$100 per ton, mostly gold.—New machinery has been installed in the El Dorado mine and development will now be accelerated.—The rich ore from the adit of the Chippewa is being prepared for shipment to smelter, a trial shipment having returned satisfactory results. Arrangements have been made to ship several carloads.—The Eldorado-Bonanza Mining Co. has been organized to take over a group of claims lying east of the Black Hawk Co.'s property. Little development work has been done so far; the ground is being prospected to determine the best place to sink the shaft.—From the 100-ft. level of the Cyrus Noble Extension driving is in progress north and south on a vein of decomposed porphyry three feet thick which carries gold and silver. This is the second vein encountered in sinking the shaft; the first, about 10 ft. thick, was 50 ft. from the surface, and there is another on the foot-wall for which cross-cuts will be started when the drifts are 50 ft. from the shaft. The richest ore is found on the foot-wall.

Searchlight, August 11.

WHITE PINE COUNTY.

It is reported that the Calumet & Hecla Mining Co. has bought 22 copper claims at Ely, adjoining the most important mines of the district.

OREGON.

JACKSON COUNTY.

At the Blue Ledge copper mine, near Grants Pass, 150 men are employed on development work. The compressor has been operated by steam, but electric power is to be installed. The Blue Ledge Co. lately bought the large holdings of the Seattle Mining Co. on Applegate river, near the mouth of Elliott creek, an ideal site for a smelter, and with it is a ditch giving a head of 150 ft., which will afford all the power needed at both the smelter and the mines. The company now has a force repairing the ditch, and putting up a building for the electric plant. It is expected to have it in operation in 60 days, and wires strung to the mines to supply power for compressors and for light. The Blue Ledge mines are in the foothills of the Siskiyou mountains and six miles from the smelter-site. The mines are just over the line in California, but the smelter will be in Oregon.

SOUTH DAKOTA.

LAWRENCE COUNTY.

The Homestake Co.'s new slime-plant, at Deadwood, is practically completed. It is thought the plant can be put in operation in October. It will be the largest and most modern of the kind in the world. About 40% of the tailing from the stamp-mills is slime. The remaining 60% (the sand) is treated in the two cyanide mills, one at Lead, the other at Central, with a combined daily capacity of 2,400 tons. The Homestake saves 75% of the assay value of its ore on the plates in the mills; the two sand-plants save 15%, and the new slime-plant will add 5%, making a total extraction of 95%. The estimated cost of this plant is \$400,000. The value of the slime is about \$1 per ton. The slime will be brought in iron pipes from the mills, and be treated by filter-presses. The chief difficulty which has confronted this process has been the cost of discharging the presses after the gold has been recovered. This trouble has been largely done away with by an automatic sluicing device invented and patented by C. W. Merrill of the Homestake, which makes it unnecessary to open a press except at long intervals. Twenty-four filter-presses, weighing 60 tons each, will be installed. The slime from 1,000 stamps in the mills comes in iron pipe-lines directly into the upper building, where two storage-tanks receive it and where the necessary lime is added. A pipe connects the sludge tanks with the filter-presses in the main building. A precipitating-room, a solution-storage building and a water-storage tank are among the annexes of the plant, which is also provided with an assay office. Electric power will be used.

PENNINGTON COUNTY.

(Special Correspondence).—The situation of the tin interests in the Black Hills may be briefly stated as follows:

For several months past there has been a good deal of talk about tin and mica in this district and there have been many announcements of sales which were about to take place but there have been no recent deals consummated. Nevertheless, it is not all smoke, and mining men, and the community generally, are on the tiptoe of expectation that a number of deals in both mica and tin will culminate soon. The Gertie mine, near Hill City, with a shaft down 500 ft., and drifts run each way on the vein, has disclosed the fact that there is good tin ore all the way down; the drifts show a large body of ore, and with a little mill it has been demonstrated that this ore can be mined and milled at a handsome profit. The new mill is fast nearing completion and is expected to be running in about a month. Some new machinery passed through Custer for the new plant, which will have 50 tons daily capacity, and will be equipped with the best modern appliances for the saving of tinstone. This new machinery consisted of two sets of rolls and one large Sturtevant crusher. They have all the men at work in the mine that can be employed to advantage, and everyone expects that the Gertie will be a success. M. L. Boyer is superintendent.

Frank Hebert is mining tin ore at his mine a few miles east of Oreville, and 10 miles northeast of Custer, and is crushing it in his two-stamp Tremaine mill. He has a 6-ft. vein of tin ore and is making an excellent showing by crushing and concentrating on a Wilfley table and shipping the concentrate East for treatment. These are the only two plants in operation at present in the Black Hills that are actually producing tin. It is reported that the Tinton Mining Co., on Bear gulch, near Nigger hill in Lawrence county, has re-organized and will soon start the mill. It is also currently reported that the old Harney Peak Tin Co., which operated in this district 16 years ago, will re-organize and work the tin mines owned by the company, amounting to about 2,000 acres of mineral ground, a good portion of which is patented. However desirable this may be, it is possible that the announcement was made prematurely. We only know at present that the attorney for the company, E. Van Cise, is in London for the purpose of bringing about the reconciliation of the London and New York stock holders, that they may unite and work their tin mines in the Black Hills on a scale commensurate with their magnitude and importance. Before the English invested largely in the mines they were examined and tested and the reports were said to be, without exception, favorable. The old tin captains of Cornwall, Vincent, Jackson, Thomas, and others, all declared that the veins were larger, the tinstone purer than those of Cornwall, and that they could be made profitable, and this at a time when tin was not half as high as today. There is a good deal of interest taken in tin just now, and many of the abandoned mines are being overhauled and developed in the tin districts of Pennington county.

Custer, August 8.

UTAH.

BOXELDER COUNTY.

A strike is reported made in the Louise Con. mines, three miles north of Willard. Fred Hillman, of Ogden, is president of the company. The adit had caved and it was in the process of cleaning up and re-timbering that the new vein was found. There are 10 ft. of high-grade copper ore.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The Winnipeg Mining Co. has constructed an ore-bin at the Belcher Mountain railway track 600 ft. from its lower adit, in which it is reported ore has been struck.—The Belcher Mining Co. has started a new cross-cut adit below No. 3. An aerial tramway is planned. The electric fan has been removed to the lower adit. The company employs 12 men. It may be another year before any ore is shipped from this property.—Work has again been suspended at the San Poil mine, where W. H. Crummer, the lessee, has broken 200 tons of ore for shipment, but for which there is no present market.—The Umatilla mine, situated one and one-half miles west of Keller, on the south half of the Colville Indian reservation, is to be re-opened. The last work done was the driving of

an adit 750 ft. which cut a vein of copper ore. It is now proposed to develop this vein.

Republic, August 4.

OKANOGAN COUNTY.

(Special Correspondence).—A. M. Dewey, manager of the Q. S. Gold Mining & Smelting Co., is making arrangements for the site of the power-plant. The company has 100,000 ft. of logs and has contracted for a sawmill, to cut 15,000 ft. of lumber per day. The company has also closed a contract for an electrical lighting and power-plant of 200 h.p. Work on a pole-line and the construction of a ditch and dam will be started immediately. The adit has passed through 128 ft. of ore. The days' paymen have been discharged, and a contract let to drive the adit an additional 100 ft. to be finished by September 20. Mr. Dewey reports that a new 2,000-ft. adit is under consideration to cut the vein at a depth of 1,200 ft. The surface shows a number of small but rich quartz veins.—The Polepick Mining Co. has re-organized and will work on the Polepick mine, in the Twisp district.—The Poland-China mine, at Chesaw, has been bonded to an Eastern syndicate for \$10,000. The Lost Canyon mine, owned by E. P. Gailliac, has been sold to a company of Ohio and Indiana men for \$10,200. The purchasers have since bonded the Grant and three other claims adjoining, all situated in Beaver canyon.—The York Mining Co. will start up its mill in a few days. This was formerly known as the Bodie mine, of Bodie Camp.

Republic, August 11.

WYOMING.

BIG HORN COUNTY.

Mark Hirsch, superintendent of the Imperial Mining Co. of Deadwood, South Dakota, says Kirwin, is one of the best mining camps he has ever visited. The mines produce ore rich in gold, silver, copper and lead, occurring in fissure veins in width up to 30 ft. and traceable for thousands of feet along their outcrop. Even though 60 miles from a railroad, a great deal of work is being done. The Galena Ridge Co. has spent nearly \$400,000, and has most encouraging developments.

CANADA.

YUKON TERRITORY.

(Special Correspondence).—What is known as the White Channel in this region is an immense deposit of quartz-gravel. It is washed and ranges from fine sand to cobbles weighing 25 to 30 lb. The most of the material is quartz, besides which there is mica-schist, quartz-schist, and smaller amounts of altered quartz-porphry, quartzite and limestone. The extent of this deposit is not yet known. It strikes through the country in an east-west direction for 12 miles or more, and is from 1,000 to 4,000 ft. wide. In some places it is covered by 'wash' from higher mountains, in others it is cut by waterways, its bedrock being 100 to 300 ft. above creeks. The workings of these gravels have been confined to small operations by drift mining, no water being available for hydraulicking on a large scale. It has been generally thought that hydraulicking was the only method of working these gravels, but the examination by Mr. A. Sydney Additon has shown that a higher recovery of gold can be made by milling and cyaniding than by hydraulicking. The gold in this gravel is of three kinds: (1) placer gold which can be recovered by hydraulicking; (2) fine gold which cannot be recovered by hydraulicking; (3) gold in the quartz boulders. The second class is most abundant. The presence of the second and third kinds makes it impossible to mine the entire deposit from bedrock to surface and mill it at a profit. The first class is confined to 8 to 10-ft. bedrock. The testing of this gravel has been done in five-ton lots, with a two-stamp mill and a five-ton cyanide plant. The samples were carefully taken, so that each represented the entire depth of the deposit. The results secured are such that the installation of a large mill is assured. This mill in operation, and the proposition more thoroughly demonstrated, other mills will follow. There are millions of tons of this material ready to be delivered to the mill. An estimate, based upon actual returns from gravel milled, shows 60c. to \$1.25 per ton profit treating 1,000 tons per day. The ground, however, is not all

dike. Some will not pay, but 80% of all the samples milled would pay. Dawson is no longer the camp for the individual miner. The creek claims, which have produced millions of dollars, no longer contain pay that can be recovered by former methods. The time of dredgers and large hydraulic plants is at hand. Large corporations are securing ground for such operations. Water in large quantities and electric power are being made available.

Dawson, July 15.

MEXICO.

GUANAJUATO.

(Special Correspondence).—A contract has just been concluded between the Mexican Central Railroad and the firm of J. J. Moylan & Co. for the building of a connecting railway from Marfil to Guanajuato. The contract is said to have been effected at \$400,000, exclusive of terminal stations.—The Guanajuato Power & Electric Co. is now closing up a deal to acquire further water-power, which will enable it to increase the distribution to 16,000 h.p. It now supplies about 6,000 h.p. In Guanajuato it will distribute about 650 h.p. to the Guanajuato Consolidated Mining & Milling Co., 650 h.p. to the Guanajuato Amalgamated Gold Mines Co., 600 h.p. to the Guanajuato Mines & Reduction Co., 1,000 h.p. to the Peregrina Mining & Milling Co. The above will be its largest individual customers.—The Guanajuato Mines & Reduction Co. will almost immediately set about increasing its present 80-stamp mill to 160 stamps, with commensurate cyanide plant.—The Guanajuato Amalgamated Gold Mines Co. will complete its 100-stamp mill and cyanide works, designed by V. B. Sherrod, about October of this year. It has also built a dam having a capacity of about 70,000,000 gal. for private use.—El Cubo property is under option to London capital.—In the Guanajuato district there are a number of small mills, as well as the larger ones afore-mentioned, under construction, namely: Nayal 20 stamps, San Prospero Mining & Milling Co. 40 stamps, La Central 10 stamps. The Guanajuato Development Co. has in the Pinguico mine one of the best paying properties in the whole camp. This mine has been earning over \$3,000 net per week for some months past.

Guanajuato, August 1.

(Special Correspondence).—The Dwight Furness Co., of this city, has entered into a contract with the Guanajuato Reduction & Mines Co. for the purchase of the products of the company's plants at Bustos and Flores.—Work on the 100-stamp mill of the Peregrina Mining & Milling Co. is being rushed. Forty of the 100 stamps will be dropping in a few days, and it is expected to have the remaining 60 in operation early in September. Good progress is being made on the 100-stamp mill of the Guanajuato Amalgamated Gold Mines Co. at La Luz, and it is expected to have the 100 stamps dropping by November 1.—The Guanajuato Reduction & Mines Co. has its tube-mill, for regrinding the ore, in operation, and is now treating 250 tons of ore daily, with splendid results. The unwatering of the mines is in progress.—Frank G. Peck, of Colorado Springs, is completing a 40-stamp mill for the handling of the ore of the San Prospero mine, of which he is the sole owner.—The Cabrestante Mining & Milling Co. has been organized in Chicago for the purpose of working the Cabrestante mine in the Nayal camp. John Kniskern and George Knapp, of Chicago, are the leading men in the new company, and the Dwight Furness Co., of this city, is largely interested with them. F. H. Hobson will have charge of the work at the mine.—The 15-stamp mill of the American Mining & Milling Co. has been running for a month with good results. The Inglesa mine, owned by the company, is producing a fine grade of milling ore, and also a big percentage of ore of shipping value. J. C. Corwin is manager of the company.—Twenty stamps are dropping at the Nayal custom mill, and the plant is doing good work for the Nayal camp. Now that an outlet for the ores has been provided, a number of mines in the camp have started active work.—The Cubo mines, which have been worked for a year past under an option by T. H. Leggett, have been returned to Cubo Mining & Milling Co., of Chicago. The company proposes to continue active development work. Gerald Rives continues as manager.

Guanajuato, August 9.

Personal.

WALDEMAR LINDGREN is at Denver.

JOHN KINKEAD is at Goldfield, Nevada.

EDGAR NEWHOUSE has returned to New York.

J. N. ESSELSTYN is now at 2536 Piedmont Ave., Berkeley.

GEORGE D. BLOOD of Salt Lake City is now at Dayton, Nevada.

GEORGE E. TILLY is manager of the Sucre gold mines, in Colombia.

J. R. FINLAY has returned to Colorado Springs from New York.

R. GILMAN BROWN has his office now at 1537 Bush St., San Francisco.

JAMES A. RICKARD is mine manager in the Aude department, France.

ERNEST W. BYRD has returned to London from Tarkwa, in West Africa.

F. L. SIZER has been appointed manager of the Gould Mines Co. of Montana.

PHILIP WISEMAN, of Los Angeles, is examining mines near Prescott, Arizona.

PERCY B. WESTON is on his way to Patagonia to direct gold-dredging operations.

H. W. TURNER is examining mines at Pine, Oregon, assisted by J. H. HARTLEY.

THOS. CARROLL is superintendent of the Saginaw Mining Co. at Custer, South Dakota.

M. L. BOYER is superintendent of the Gertie tin mine, near Hill City, South Dakota.

D'ARCY WEATHERBE has accepted an appointment with Phelps, Dodge & Co. at Bisbee.

J. A. DRYDEN has been appointed manager of the Pinkham mine, at Chloride, Arizona.

C. W. PURINGTON is at Eureka, Colo., examining mining property in the San Juan district.

RENSSELAER H. TOLL has moved his headquarters from Mancos to Cripple Creek, Colorado.

E. J. KNIGHT is manager of the property of the Chiquita Con. Mining Co., at Searchlight, Nevada.

C. M. FUELLER has been engaged professionally at the Dives-Pelican mill, Silver Plume, Colorado.

E. J. KENNEDY is manager of the Golden West mine, on Castle creek, near Rochford, South Dakota.

WILLIAM GARRISON has left Cananea, to become foreman at the La Dicha smelter, in Durango, Mexico.

HENRY J. GIFFORD has been appointed superintendent of the Champion Reef mine, in Mysore, India.

EMERSON GEE has returned to Los Angeles from mine examinations in the Blue River district of Oregon.

F. W. BOCK has gone from Rochford, South Dakota, to his mines in the Warren Peak region of Wyoming.

J. F. EISMAN of Denver has been inspecting mines in which he is interested at Breckenridge, Colorado.

HORACE G. NICHOLS, manager of El Transito and Porvenir mines, in Nicaragua, is on his way to London.

C. W. WHITLEY, manager of the Garfield smelter, has returned to Salt Lake City from a visit to San Francisco.

C. O'BRIEN has gone to La Cunibre, Sinaloa, Mexico, to take charge of the mill of the Galanista Mining Company.

JESSE A. STEWART has accepted a position as mining engineer with the De Lamar Co., Ltd., at De Lamar, Idaho.

G. C. HEWETT has returned to Colorado Springs from the San Juan region, where he has been examining several mines.

EDWIN W. MILLS has resigned as assistant superintendent of the Oriental Consolidated Mining Co., Chemulpo, to become superintendent of the Chiksan mines, also in Korea.

JOSEPH IRVING has been appointed superintendent of the Continental Smelting & Refining Co., at Ironton, Colorado.

THOMAS McCORMICK has been appointed superintendent of the Con. Virginia and California mines, at Virginia City, Nevada.

E. C. THURSTON, of the Empire Zinc Co., Canyon City, Colo., has been examining zinc mines on Arrow lakes, British Columbia.

HENRY ARGALL, the oldest son of PHILIP ARGALL, was married on August 3, at Martinez. He is metallurgist at the Selby smelter.

JOHN D. PLATTS is making surveys and plans for the installation of a large hydraulic plant on Myrtle creek, Del Norte Co., California.

J. BOYD AARONS is now manager of the consolidation of the White Feather Reward & White Feather Main Reef mines, Western Australia.

R. H. SUTTON is superintendent of the Copper World mine, for the Cocopah Copper Co., at Ivanpah, in San Bernardino county, California.

CLERMONT LIVINGSTON is general manager of the Tyee Copper Co. and recently received the thanks of the shareholders for his able services.

H. S. KENNEDY has resigned the management of the Lakeview Dredging Co., at Neeley, Idaho, and will leave Butte, Mont., shortly for Johannesburg, South Africa.

G. C. KLUG, who recently resigned as resident manager of the Gt. Boulder Perseverance mine, has become manager of the Phillips River gold and copper mines at Ravenshorpe, also in Western Australia.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

A MODIFICATION of the caving system of mining is being introduced at the Cananea mines.

CHROMITE generally occurs in serpentine. The poorer ore scattered in the serpentine can be concentrated to a high-grade product without trouble. A rude concentration can be made by sluicing.

COVER-GLASSES for microscope slides sometimes appear dingy and it seems impossible to clean them. This may be easily done with a weak solution of sulphuric acid, when water, alcohol, rouge and other things fail to give the desired results.

A TEST of tube-mills for treatment of diamond-bearing rock is being made at the gold mill of the Village Main Reef mine at Johannesburg, Transvaal. The diamondiferous ground came from the Pretoria mines—the test run being 1,000 loads.

A PATENT has recently been issued in the United States for a method of desilverizing lead bullion, the process being in the addition of metallic zinc to the molten bullion, and then adding sal-ammoniac to cause a more complete separation of lead and silver.

THE Seattle, Wash., assay office reports its gold receipts for the first half of 1906 as \$20,000,000, of which about \$7,000,000 came from the Tanana district, \$5,000,000 from Nome district, and the balance from other parts of Alaska, Yukon basin and from the Pacific Northwest.

PASSENGER ELEVATORS in buildings seldom run at a speed exceeding 800 ft. per min., and the greater number run below 500 ft. per min. A mine cage or skip running at this speed is considered slow. Maximum speed in mines ranges from 2,000 to 6,000 ft. per minute.

THE metre is the unit of length of the metric system of weights and measures, and was intended to represent the one ten-millionth of the quadrant of the earth, measured on a meridian from either pole to the equator. The gram is the unit of weight which is the weight of a cubic centimetre of pure water at its greatest density—4.5 deg. C. or 40 deg. F. The latitude is a negligible factor.

YELLOW OCHRE is used in the manufacture of oilcloth and linoleum, and to a small extent in the manufacture of paint. The calcined ochre makes a dark red pigment. Yellow ochre occurs commonly in quartzite, particularly the Cambrian. It is abundant at Cartersville, Ga., and is common in some portions of Colorado and in the Black hills of South Dakota. At Red Cliff, Colo., and in the Bald Mountain district of the Black hills, these ochre deposits carry gold in payable amount.

IN 1880 the annual gold production of the world was about \$100,000,000, and that of the United States was about \$30,000,000. In 1900 the world's gold production had increased to nearly \$300,000,000, and that of the United States to nearly \$80,000,000. No one can predict what the future output of gold will be. Important factors in production are the discovery of new gold districts, the development in old districts of new orebodies carrying gold, and more than either of these is the introduction of processes which makes the treatment of low-grade ore and tailing profitable. At present, dredging is also an important and increasing factor.

THERE are now in successful operation in Butte three blast-furnaces each 52 ft. long, and one of them is being enlarged to 89 ft. There seems little doubt that this large furnace will prove as successful as those of only a little over half this length. What the ultimate economic limit in size of a copper blast-furnace will be, it seems impossible to say.

THE Niagara, Lockport & Ontario Power Co. has planned to transmit electric power with aluminum cables from Niagara to Syracuse, N. Y., a distance of 160 miles, and is considering a line to Cleveland, O., a distance of 200 miles. The Niagara and Syracuse line is partially finished. Many miles of aluminum line are in successful use as a carrier of electric current in California.

MINERAL VEINS exist in rocks of every geological age, but are most numerous in regions consisting of sedimentary rocks intruded by igneous rocks, though regions in which only igneous rocks occur also often contain many mineral veins. Although veins occur in metamorphic sedimentary rocks, unaccompanied by intrusive rocks of any kind, largely profitable mines in veins of this class are not abundant.

COPPER, after converting, always contains copper oxide which must be reduced to metallic copper. This is accomplished by what is known as 'poling.' For this purpose a large long pole of green wood, of any kind, is introduced into the refining furnace, which being burned in the metallic bath, results in the evolution of a large amount of hydro-carbons and other reducing gases, the presence of which quickly changes the copper oxide to metal. The poling, according to Peters, is continued for about 60 min., or until a full-sized ingot (on being poured) shows no contraction or depression on cooling, and the texture is fibrous and silky.

A SIPHON practically ceases to be effective at a depth greater than 28 ft. at the sea level, and the apparatus must be nearly perfect to operate satisfactorily to that depth. As the altitude above sea level increases the depth to which the siphon will operate becomes correspondingly less, owing to decreasing atmospheric pressure. The lower end of the outer limb of the siphon must be lower than the surface of the water, or it will not work at all. In Beaver Head county, Mont., it is probable that a siphon will not operate to a greater depth than 18 ft. vertical, therefore, it would not be an economical or sensible idea to attempt to install a siphon with a pipe line over 2,000 ft. long to raise a small amount of water from a maximum depth of 18 ft. Rubber hose suitable for such purpose would cost at least 12½c. per ft., making the outlay for hose about \$250, and a leak would probably end its usefulness as a siphon. The cost of iron pipe 1½ in. diam. at the mine in question is unknown to us, but is probably not less than that of the hose when in position in the mine. The suggestion to operate a gas-engine of any description 2,000 ft. from the portal of an adit cannot be given a moment's consideration. The best thing to do is to operate an electrically driven pump in the shaft, and the next best is to place an air compressor at the mouth of the adit and run a pipe line to the face and down the shaft to a sinking-pump. Both of these propositions are feasible. A third method is by means of the hydraulic lift or ejector. This requires a relatively large volume of water, under high head, to discharge a small amount of water to comparatively limited height. In a small plant, of this description, there is danger of the ejector becoming clogged with small debris from the sump. The electric pump is probably the best of the several means of handling the water. It is direct, efficient, and not an experiment.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Zinc-Dust vs. Shaving.

The Editor:

Sir—During the last few years I have had occasion to visit many cyanide plants in different parts of the country, and have noted with great interest the methods employed in different sections. While in the Black Hills a few years ago I observed with great satisfaction the apparent success of zinc-dust precipitation, and noticed with what economy in labor great volumes of solution were handled. The question arises in my mind, Why is zinc-dust precipitation not more universally employed? All cyanide operators are well aware of the great amount of labor necessary to keep zinc-boxes properly dressed and in good working order, to say nothing of the labor involved in the monthly or bi-monthly clean-up. In point of economy in labor, zinc-dust precipitation certainly has the advantage over precipitation on zinc shavings. If it is all that could be desired in other respects, why would it not be economy to design all plants of moderate size with this process?

I think a discussion of the subject by those employing the process, giving figures as to cost of installation and operation, efficiency, etc., would be read with great interest by cyanide operators.

CYANIDE MAN.

Goldfield, Nev., July 28, 1906.

Zinc-dust precipitation in cyanide work possesses distinct advantages over zinc-shaving, and has been employed with marked success at the cyanide plants of the Homestake Company in the Black Hills. This process was evolved there after diligent study, but all the details have never been given to the public, and it is possible that the success of the process at the Lead City plants may depend upon some important trick of manipulation which the management wishes to conceal. Many attempts have been made to use the process at other plants, but without success. It would be difficult to assign the cause for this failure. It may be due to the reluctance of operators to supplant a simple and reliable process for one comparatively complicated and untried; but it would seem to be due in some instances to unfavorable conditions for precipitation, or it may be altogether due to having missed the one feature essential to success, as known only to the Homestake operators. The reason for the continued popularity of zinc-shaving is obvious. The process is simple and appeals to the average intelligence. We join with our correspondent in his wonderment at the slow introduction of zinc-dust, and venture to predict that as soon as the process gets a fair start and the principles of its use are better understood, it will easily supersede the cumbersome method in vogue at the present time. We shall be glad to publish the views of cyaniders on this subject.—EDITOR.

A Mining Method Wanted.

The Editor:

Sir—Since the original article appeared, which resulted in a discussion of the best method of mining a large vein having a low angle of dip, several engineers have contributed from their experience to our common fund of knowledge.

The method proposed by Mr. R. B. Nickerson seems to have answered every requirement in the instance mentioned by him, but I doubt whether he could get equally satisfactory results in the application of this method to a

vein as large as that under discussion. His scheme is ingenious, nevertheless, and deserving of a trial. The proposition of cutting the shaft by raising on the foot-wall of the vein from the adit-level, instead of sinking from the surface, is worth consideration, and could be adopted whether the raise be cut in the vein or in the foot-wall country rock beneath it, as described by me. In the latter case, after the raise had reached a point 100 ft. vertically above the adit-level and a stope had been well advanced between the adit-level and the first level above it, the waste broken in the raise above that level (which might be designated as No. 5), could be trammed through a cross-cut to and across the vein on No. 5, and dumped in the stope below for filling. The method of handling cars in this raise, as described by Mr. Nickerson, is admirable and could be economically applied in many cases, not only in flat raises, but in some instances in stopes as well.

The proposition of Mr. R. H. Sutton seems feasible, but I cannot perceive that it has anything to recommend it over the method already suggested. The ore-pockets under the stations, cut as indicated in Mr. Sutton's sketch, are needlessly large, as the ore will not run on the flat slope of 23 deg. which is the inclination of both shaft and vein, consequently there would be only a small amount of ore in the lowest part of each pocket that would run to the skip. In the gangways, chutes from the stopes at intervals of 20 ft. are unnecessarily close, and would consequently involve a small increase in the cost of mining. The proposition to shovel ore from the stopes into mill-holes is little, if any, improvement on my suggestion to shovel directly into cars from the sill-floor, with the possibility of drawing the ore through the chutes without the necessity of shoveling, should the ore break small. In this event cribbed chutes carried up as suggested by Mr. Sutton would be unnecessary. The running of cross-cuts in hanging and foot-wall country to obtain filling would be found expensive. For each section of stope 50 ft. wide, 100 ft. high and extending from wall to wall, there would be required about 30,000 tons of waste rock for filling. The obtaining this filling in cross-cuts at the very low expense of 60c. per ton for breaking, shoveling, tramping and placing in stopes would be \$18,000, or about 36c. per ton of ore extracted from the stope, and if this large tonnage of waste were to be handled by wheelbarrow, as suggested by Mr. Sutton, the cost would be increased to \$1 or more per ton of ore removed from the stope. Each 50 ft. longitudinal stope would require about 4,000 linear feet of cross-cut 10 by 10 ft. in section, to supply the necessary amount of filling.

Mr. D'Arcy Weatherbe favors the stoping scheme of 'The Prospector,' but believes with Mr. Nickerson that there would be an advantage in raising to the surface instead of sinking, and also favors placing this raise on the foot-wall instead of beneath it. The raise, or shaft as the case may be, could undoubtedly be cut as well on the foot-wall as beneath it, but this would necessitate the leaving of large wedge-shaped masses of ore on each level which could not be readily removed by the stoping system suggested by me. The latter's scheme does not contemplate stoping barren rock from the foot-wall as Mr. Weatherbe appears to think, though the sketch might lead to such conclusion. The intention was to cut into the foot-wall at the ore-pockets only, merely to facilitate working, and was a part of the economy of the system. The small amount of ore remaining under the sill-floor of each stope, on the hanging-wall side, could be readily mined and sent down into the next adjoining stope, as it is all within easy reach of the timbering on the line dividing stope and pillar. The entire amount to be thus handled would not exceed 1,000 tons to each 100 feet of longitudinal stope, whereas, by Mr. Weatherbe's

scheme, this wedge would contain about 5,000 tons of ore in each 100 ft. longitudinally of the vein, the additional cost of handling which by any method would go a long way toward offsetting the difference in cost of placing the raise, or shaft, under the vein in the foot-wall.

The reason for hoisting through the shaft was to facilitate reaching a mill already on the property, which fact should have been stated in the original proposition. My plan for obtaining filling contemplated only the cutting of a single shaft or raise, connecting with the open-cut on the surface, and the distribution of the rock to the stopes by a series of mill-holes, sunk from the drifts, run over each line of stopes. Obtaining and placing filling by this method should not exceed 20c. per ton of ore extracted, if the ore-shoot proved to be 300 ft. or more in length. The scheme suggested by Mr. Weatherbe, that the stopes be mined without timber, or filling, until a cave threatened, makes no provision for subsequently safely obtaining the ore remaining in the block at the time of the cave. Of course a pillar-and-stall method might be adopted throughout, but the value of ore necessarily left standing in the mine would probably amount to more than the cost of getting all of the ore by a somewhat more expensive, though safe, method. It seems unnecessary to state exactly the value of the ore, the object being to get a mining method not necessarily dangerous and which permits the removal of the maximum amount of ore at the least expense. There is no reason why a more expensive system of mining should be adopted on a rich orebody than would be applied to the extraction of ore that is low grade.

THE PROSPECTOR.

August 3, 1906.

THE surveyors-general are appointed by the President for the respective surveying districts. They have the appointment of deputy mineral surveyors at their discretion, although their action in suspending or revoking appointments of deputies is subject to review by the general land office before final action is taken. They are not permitted to make surveys in a district for which they hold no commission, and they are not permitted to act in the double capacity of surveyors and attorneys for mineral applicants at the same time. They are *not* prohibited from making mineral entries in their own name in the district for which they are appointed, but in that event they cannot act in any other capacity than that of claimant; that is, they cannot survey their own claims, nor any claim in which they have an interest, for patent. In consideration of the foregoing, the Nevada deputy mineral surveyor was within his legal rights when he relocated an abandoned claim, and the lessee had no rights in the premises further than was conveyed by the terms of the lease. As to his dismissal as deputy surveyor, it would probably be difficult to secure a review now and to be reinstated in office. It would probably be more profitable to oust the jumper by legal process, as he has no color of title if the case has been properly stated.

A SERIOUS DETRIMENT to the making of a road in Alaska is the thawing of the ground beneath the moss. It has been the universal experience that wherever the moss is cut into, thawing immediately commences, and the trail which was passable becomes a filthy, slimy mass of mud, roots and broken stones—a difficult route for men on foot, a slow and tiresome road for loaded animals, and an impassable obstacle to any sort of vehicle. In regions farther south, under temperate conditions, trails frequently are developed into fair wagon roads by much usage. Such developments can never take place in any part of the Northwest.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

The rock from Prescott, Ariz., marked Thum Butte, is Hornblende-andesite.

Rock samples marked B. M. Co. are determined as follows: No. 1, 2 and 3, Andesite; No. 4, Hornblende-schist.

The rock from Tehachapi, Cal., marked F. A. F., is Quartz, in which is embedded the common brown variety of Garnet.

The samples from Ingot, Cal., marked C., are: No. 1, Garnet (brown) and Halloysite (yellow); No. 2, silicious iron ore and a little Malachite (copper carbonate), and Chrysocholla (copper silicate).

The rocks from Tombstone, Ariz., marked A. G., are much decomposed. The smaller, darker piece, is much altered Granite, or Diorite, infiltrated with calcium carbonate. The larger piece is a mass of rock fragments of many kinds, partly water worn and cemented by carbonate of lime.

The rocks from Edgewood, Siskiyou county, Cal., marked J. D. E., are: No. 1, Epidote; No. 2, Aplite; No. 3, principally Magnetite, with a film of Malachite (green copper carbonate); No. 4, Barytocalcite; No. 5, Hornblende, with disseminated magnetite grains; No. 6, Chromite; No. 7, Chromite, somewhat decomposed; No. 8, Tale-schist; No. 9, Cinnamon stone (garnet).

The rocks from Cœur d'Alene, are: No. 1, slightly schistose greenstone, probably originally Diorite. One piece exhibits slickensides, due to pressure and movement within the rock mass. It is partly altered to tale-schist; No. 2, a very silicious Aplite, discolored by iron and manganese oxides; there is also a development of scales of black and white mica of secondary origin; No. 3, the grayish-white honey-combed piece is also Aplite, less silicious, and at one time evidently contained pyrite which has been oxidized, leaving the numerous cube-like holes, some of which contain iron oxide.

INVESTIGATIONS IN EGYPT made by the Government in 1904 and 1905 in the desert between the Nile and the Red sea, starting in near the town of Edfou, are encouraging to both old mines and new. At the northernmost point of the mineral fields is the concession of a Cairo syndicate, which is prospecting in the northern half of the Sinai peninsula. The discovery of copper is reported. Another syndicate, while prospecting for coal and other minerals to the south of latitude 28 deg., and to the north of the Egyptian Mines Exploration Co., has found extensive ancient workings in the neighborhood of Jebel Zeit, about 12 miles from the Red sea. This is the most northern point at which ancient gold mines have, as yet, been discovered. The concession of the Northwestern Exploration Co. lies on the west side of the river. At the Um-Rus Gold Mining Co.'s mine, in the southeast corner of the concession, a large plant has been erected. The main shaft is down 550 ft. The present output varies between \$6,000 and \$8,000 per month. To the south, E. W. Streeter has a concession to work the emerald mines and also a prospecting license for other minerals. Ancient workings of gold, lead, copper, iron, emeralds and sulphur are known to exist there. Practically all the mines are within 30 miles of the Red sea.

Copper at Butte, Montana.---II.

Written for the MINING AND SCIENTIFIC PRESS
By ARTHUR H. HALLORAN.

The Butte mines may be most logically listed and described by means of the holding companies. The Amalgamated Copper Co. holds the controlling interest in many of the big producers. F. Augustus Heinze formerly operated several adjoining mines, through the Montana Ore Purchasing Co. and the United Copper Co. The history of the bitter feud between the two controlling interests at Butte is famous. In February of this year Heinze's interests were bought by persons friendly to the Amalgamated Company, and a new company was formed, known as the Butte Coalition. This is merely a holding concern, as the mines are to be worked by the Red Metal Mining Co. A. C. Carson is manager of this, as well as of the North Butte Mining Co. W. A. Clark operates through the Original Mining & Smelting Co. Other organizations will be described in the order of their incorporation.

The subsidiary companies of the Amalgamated yield 10,000 tons of ore daily; they include the Anaconda Copper Mining Co., the Boston & Montana Consolidated Copper & Silver Mining Co., Butte & Boston Consolidated Mining Co., Washoe Copper Co., Parrot Silver & Copper

Co., and the Trenton Mining & Smelting Co. The North Butte Mining Co. is closely allied to these, as is indicated by its list of shareholders, and as was shown in the courtesies extended during the temporary inability to hoist ore.

The Anaconda Copper Mining Co. is operating the

Lowering Timbers in a Stope.

Moonlight Mine.

Never Sweat shafts are 2,450 ft. deep, the St. Lawrence 2,200 ft., the High Ore, Diamond and Mountain Consolidated each 2,200 ft. and the Bell 1,600 ft. The High Ore is being continued to the 2,400-ft. level. Each shaft has three compartments, the High Ore shaft being the best equipped; through it all the water from the Anaconda, Washoe and Parrot properties is being pumped. This is done in three stages from the 2,200-ft. level to the 1,600, then to the 900, and finally to the outlet on the 350-ft. level. Each pumping unit comprises three Dickson pumps, with a combined capacity of 1,500 gal. per minute.

These mines offer but few novel features in methods of working. The standard system of overhand stoping has given the best results. As a rule the ground is heavy, so that all stopes have to be closely timbered and filled. The expense of this timbering has been enormous, as square timbers 10 by 10 in. cost as much as \$17.50 per thousand feet. Occasionally, particularly in the Anaconda and Never Sweat mines, the big veins carry firm walls. These veins will run from 25 to 40 ft. wide and both their foot and hanging walls stand well. For working them a peculiar method of 'back filling' has been designed in order to lessen the consumption of timber. Drifts are run along the vein at each 100-ft. level, as is customary in all overhand stoping. At intervals, raises are made between levels, each raise consisting of chute and manway, timbered in the ordinary manner. Above the regular drift-sets the ore is stoped out to a height of 10 ft. above the sill-floor. Stulls, placed perpendicular to the hanging wall, are firmly wedged into hitches. On these is laid a cover of lagging or plank, protecting the drift-sets below. This serves as a floor, the stope commencing at the main raise. The muckers shovel the ore back to the raise until this distance becomes inconvenient. Another chute is then cribbed, the ore being shoveled or carried in wheelbarrows to this outlet. These chutes are placed 30 to 50 ft. apart, wheelbarrows being used when the maximum interval exists. Waste is run down the main raise to be used as filling when the ore is removed; a temporary track serves to distribute this material. These farther raises are cribbed up with round timber as the work advances. Thus the ore is removed in slices for the full width of the vein up to the next level. For the widest veins a lateral is run parallel to the drift and connected with it by cross-cuts at each of the raises. Great care is exercised when the stopes approach the level above; if the ground shows signs of giving, sprags are put in or square-sets are placed on top of the filling.

Electric call-bells and electric lighting are used in these mines as in most of the other Amalgamated properties. Horses or mules do most of the tramming. The animals are seldom brought to the surface, yet they seem in fine condition. They are great friends with the miners and generally get an apple or lump of sugar from the lunch-pail. It is figured that a horse does as much as ten men. On the main levels of the Anaconda, Never Sweat and St. Lawrence mines compressed-air locomotives are used. On the 1,400-ft. level of the St. Lawrence, an endless chain handles the car for 1,200 ft.; most of the skips are loaded from the chutes at the station and automatically are dumped into the surface bins. Double-deck cages with eight-ton skips attached are customary. The Mountain Consolidated employs four decks and the High Ore three. Flat cables from 6 in. to 8 in. are used. Both round and square timbers are found in the drifts, and square-sets in the stopes.

The Never Sweat power-plant contains five Ingersoll-Sergeant compressors, furnishing power for 360 drills in the Never Sweat, Anaconda, St. Lawrence, Moonlight, Mountain View, High Ore and West Colusa mines. Electric motors, with a steam auxiliary, are bolted to

the compressors. The machine-drills in the Bell and Diamond mines are supplied with air from two Ingersoll-Sergeant compressors at the Diamond.

The Boston & Montana Co. owns and operates the Leonard, Pennsylvania, Mountain View, West Colusa and East Colusa mines, all within the boundaries of 'the hill.' In addition, many surrounding claims of this company are worked by lessees. The Leonard has two shafts, each 1,200 ft. deep. The Pennsylvania is down 1,885 ft.; the West Colusa, 1,600 ft.; the Mountain View, 1,800 ft., and the East Colusa, 900 ft. Sinking has been started for the 2,000-ft. level in the West Colusa. As each compartment in the West Colusa is 5 by 9 ft. they use single-deck cages hoisting two cars on the same cage, placing one behind the other. Flat ropes are in use at all the Boston & Montana mines except the East Colusa, which uses 1½-in. round cable. A Webster Camp & Lane hoist, 28 in. by 72 in. cylinders, and flat cable ½ in. by 7 in., has recently been installed at the West Colusa. It is designed for a depth of 3,500 ft., and has double-deck cages with six-ton skips attached. All stopes are closely timbered, and filled, where possible. Considerable round timber is used in both drifts and sets. Framing machines are used at these as well as at most of the other important mines. At the Leonard 12 by 12 in. and 14 by 14 in. square timbers are used in many of the stopes, as the lode is wide. Solid bulk-heads are brought up into the stopes to insure good blocking for the timbers. Sectional overhead stoping is used throughout. Men tram the ore from the stopes to the main level chutes, whence horses haul the cars to the surface. Heretofore the ore has been hoisted in cars in all the properties, but on account of the expense and loss of time skips have been put in at the new Leonard, Mountain View and Pennsylvania shafts.

All the water from the Boston & Montana properties is pumped through the old Leonard shaft from the 1,200-ft. level to the surface. At the station is a Nordberg pump having a capacity of 1,000 gal. per min., throwing to a height of 1,180 ft. As a relief at the 700-ft. level a 700 gal. Knowles pumps to a Reidler, which pumps to the surface. The plant is now handling about 600 gal. per min. As this, as well as all the water from the Butte mines, is strongly acid, copper linings are used throughout.

The company has built a precipitating plant at the Leonard, which is an interesting example of the recovery of what was formerly a waste product. The plant consists of a series of troughs, towers, and tanks filled with scrap wrought iron. On it the copper from the acid water is precipitated, afterward brushed off, collected, dried and shipped to the smelter. It takes 100 lb. iron to produce 67 lb. copper. The heaviest kind of iron is used at first, decreasing in size toward the end of the plant. For miles below, this same water, after percolating through tailing piles, is re-worked by lessees, although the company saves 97% of the original copper content. The lessees are forced to use tin cans in most of their work, as the acid strength is much reduced when it reaches them. The Parrot Mining Co. is also precipitating cement copper from its old tailing dump.

During the year ending June 1, 1906, the Boston & Montana Co. extracted 1,209,805 tons of ore, averaging \$12.82 per ton in copper, gold and silver. The cost of mining was \$3.46, of transportation for 172 miles to the smelter \$0.93, and of reduction \$2.45 per ton. The Anaconda Co. extracted 1,521,310 tons, yielding \$10.92 per ton, and costing, for mining \$3.63, transportation 27 miles \$15, and reduction \$2.27 per ton.

CRITICISM rarely succeeds in being both penetrating and polite.

The Steam-Shovel at Bingham.

Written for the MINING AND SCIENTIFIC PRESS
By LOUIS S. CATES.

The properties of the Boston Consolidated Mining Co. are situated in the Bingham mining district about 28 miles southwest of Salt Lake City. They are reached by the Rio Grande Western Railroad. The altitude of the mines varies from 6,000 to 7,500 ft. The company owns about 365 acres of mining property with a general northeast and southwest trend. The southwesterly portion includes the limestones and quartzites in which the copper sulphide orebodies are situated, and from which 600 to 700 tons of smelting ore are being shipped daily. Sulphide ore has been produced for about three and a half years.

It was not until February, 1905, barely seventeen months ago, that development work was started in the

practice developed in the iron ranges was not exactly applicable to the porphyry; in consequence the equipment is a composite representing the experience of several engineers.

The porphyry is covered with a capping of surface loam and oxidized ore for a thickness varying from 15 to 70 ft., and the first task is to remove this waste preparatory to getting at the ore.

We had to devise an economical method for breaking the ore; air-drills were not deemed suitable; the machines would be too large and they would be unable to go down the 60 to 70 ft. necessary in some parts of the property. Furthermore, the porphyry is full of small cleavage cracks which would easily cave holes the size an air-drill would put down. The question resolved itself into finding a machine which could be put to work as near as possible to the point of power generation,

Carr Fork, Showing Railroad Which Will Dump Waste from the Other Slope.

northeast portion of the property, which covers 75 acres of the copper-bearing porphyry. During that time an aggregate length of four miles of prospecting tunnels has been done for a distance of about one mile on the strike of the porphyry. The results of this work have been so encouraging that preparations are being made for mining a large tonnage to supply the mammoth mills now in course of erection in the valley.

The porphyry deposit is of stupendous dimensions; it rises in a mountain 700 ft. above the creek-level, and from results of diamond-drill holes, it is known to warrant mining from 300 to 400 ft. below the creek-level. After this ore-zone had been thus tested, it became evident that no ordinary method of underground mining would meet the necessities of the case, it being the purpose to extract 4,000 to 5,000 tons daily. Our ideas at once turned toward the steam-shovel as a machine for handling such an immense tonnage and after careful study this was chosen as being the only practical solution of the problem.

The Boston Consolidated Co. was the first to commence actual shoveling in the camp, so that we had no precedent to follow. The task was not an easy one, for the

thereby diminishing the various mechanical losses, and one which would drive a hole sufficiently large at the bottom to hold the charges of black powder. The Keystone well-drill, size No. 3, proved the ideal machine. This drill is self-contained, having its boiler and engine mounted on wheels; it is self-propelling and uses a $5\frac{3}{8}$ -in. bit, capable of sinking from 60 to 70 ft. of holes $5\frac{1}{2}$ to 6 in. diam. per 12-hr. shift.

To dispose of this waste capping after being broken, a two-mile railroad was started in February, 1906; this railroad is a continuation of the Copper Belt railroad on the west slope of the mountain and continues around it to the east slope, where the porphyry lies. The scheme is to load the dirt on the east slope and with a run of about one-half mile on a two per cent grade to dump the waste in the large canyons on the west slope, which are mostly in barren quartzite, so as not to interfere with any mining operations.

To handle the broken material a 95-ton Vulcan shovel with a three-yard dipper is being used, loading into four-yard side-dump narrow-gauge cars in trains of ten cars each, pulled by 18-ton saddle-back engines. Four engines are used in attending the shovel and one other is in reserve,

The porphyry breaks small and makes excellent material for shoveling. The shovel handles 400 cars or 2,500 tons per 10-hr. shift. As for costs, they are not obtainable yet, for operations were only begun on June 23; but judging from this short period, the costs should be below 12c. per ton. By September 1 this equipment is to be trebled, so that it will consist of three steam-shovels, 14 engines and 175 dump-cars.

THE geologist, miner and prospector naturally expect to find in Wyoming, situated as it is between Montana and Colorado, rich mining districts, but up to the present extensive or remunerative gold and silver deposits have not been found. In 1868, in the Wind River mountains, gold placers and veins were found and these were worked for several years, producing in the aggregate \$500,000. The principal camps were at Independence, Miners' Delight, South Pass City and Atlantic City. Within the past year or two there has been a revival of mining activity in these old districts. In eastern Wyoming some gold—placers and quartz—and some tin ore has been found in the Black Hills, and also gold and copper near Warren's Peak in the Bear Lodge range, northwest of the Black Hills. At Grand Encampment, in Carbon county, and at Rawhide Buttes, in Laramie county, are copper deposits. Judging from the float, copper ore and copper-stained quartz scattered over the Wyoming plains, near the Laramie range, there is copper in these mountains as well. The most promising portion of the State for the prospector is the northwestern part in the Shoshone, Teton and northern Wind River ranges, where old crystalline schist—Archean or Algonkian—are flanked by up-lifted sedimentary rocks of Paleozoic time. If a region of intrusive dikes, or laccolites, can be discovered in any of these mountains, the prospector's chance is good for finding new and profitable mining districts. That region is extremely rugged, several hundred miles from the nearest railroad, and of it comparatively little is known. The region described is probably the largest area in the western United States where there is a reasonable chance of finding good mines, that has not already been run over by that advance agent of civilization—the prospector.

THE CHINESE make iron direct from ore, in China, by mixing four parts of ore, one part of small coal, and one part of decomposed coal dust, this mixture being placed in a crucible about 18 in. deep and 6.5 in. diam. The soft, decomposed coal is obtained from the upper portion of veins along the out-rop. The crucibles are heated in a small furnace, having walls about three feet high, the rear wall being that of a small hut which shelters the men who work the bellows supplying the blast. The floor of this furnace is about 4 by 6.5 ft. and is covered with clay, on which is spread seven to eight inches of coarse coal. On this 60 or more pots are placed, the space between them being filled with small coal, and the pots are covered with a layer of small coal a few inches thick; over all is placed a layer of cinders and ashes to the depth of several inches, the front space being filled up with old crucibles. After 16 hours of strong heat the fire is allowed to burn down and the crucibles are removed and broken, each containing a small mass of carbon iron, which is made into wrought iron by re-heating over a wood fire and hammering while still red hot.

ABOUT 400 ft. per min. is a fair rate of hoisting in a shaft with ordinary winding machines, such as are usually installed at shafts 500 to 1,000 ft. deep, and where the amount hoisted daily does not exceed 400 to 500 tons. Large hoisting engines designed for much greater capacity, and greater depth, wind at the rate of 1,000 to 6,000 ft. per minute.

On the Cumbre de San Manuel Trail.

Written for the MINING AND SCIENTIFIC PRESS
By COURTENAY DE KALB.

At the present moment the extreme southwestern portion of Chihuahua is the most inaccessible and unsubdued part of the Mexican Republic. Though there are many districts surpassing it in the picturesque, none approaches it in the rugged grandeur of its mountains and in the solemn impressiveness of its mighty canyons. Nowhere else in North America exists so wild a labyrinth of deep-cut gorges, and nowhere will the traveler journey so far and make so little effective progress as in the upper water-shed of the Sinaloa and its splendid tributary, the Bazonopa. During a five days' journey the snow-clad peak of Muinora was the one prominent landmark, re-appearing from every eminence reached on the trail, its distance seemingly undiminished, a sublime spectacle, like a worn sphinx in shape, set upon a massive rectangular pedestal at the end of the longest and highest ridge of the central Sierra Madre. It may convey a stronger impression of the mighty effects of stream-erosion which have been produced in this portion of the great range of western Mexico, to be told that in the midst of these pine-clad summits, where the snow lingers late into summer, a half-hour's ride will lead one down to pretty *vegas* nestling under the canyon walls where a semi-tropical climate favors the culture of bananas, papayas, and sugarcane.

Unlike the great canyons of Colorado and Arizona, which have for the most part been carved out of feebly resisting sandstones and shales, the gorges of the Sinaloa and Bazonopa have been cut through rhyolites and andesites, the latter forming an ancient floor upon which the rhyolites have been poured in successive layers. As denudation has revealed the geological structure of the region, these layers stand forth in strong relief on the canyon walls, simulating stratified rocks, and often producing a series of terraces, while the jointure adds a columnar effect which gives to some of these occurrences a striking resemblance to gigantic cathedral organs.

The original pathfinder through this bewildering maze of mountains was, of course, the Indian, but the Spaniard was equally intrepid as a blazer of trails, with the added difficulty of having to pick a way for his horses and mules. Nothing could daunt him in his search for gold, and apparently no wilderness could long preserve its treasures hidden from his sight. A short distance east of the Bazonopa river, only 26 miles as the crow flies, but fully 65 miles by the tortuous trail, are the famous mines of Guadalupe y Calvo, which were discovered in 1838. The output of precious metals from these bonanzas was so great, in the first seven years amounting to 162,562 oz. gold and 5,869,267 oz. silver, that the Mexican Government established a mint in this remote section of the mountains in 1844, and a large commerce flowed over trails leading eastward to the central plateau, and westward to the fertile lowlands of Sinaloa and the ports on the Gulf of California. Twenty years later another excitement was produced by the discovery of a new bonanza at the Cumbre de San Manuel, three miles from the Bazonopa river, followed by the exploration of many other veins in the same district. The most interesting of these was the Guadalupe, which was the scene of active and profitable mining for a decade. The ore was difficult to treat, but the native metallurgists secured a fairly good extraction by roasting in *adobe* reverberatory furnaces, and subsequently grinding and amalgamating in *tahonas*. Report credits these ores with having averaged an ounce in gold to the ton, which was probably true for the richest shoots, and the vein was esteemed so rich that the local regulations allowed to each

miner a claim only 35 ft. in length on the outcrop. As a result of this restriction mining was conducted by a series of open stalls, from which in a few cases shafts were sunk from 60 to 125 ft. deep. The greatest depth of vein worked was only 185 ft., the value decreasing below the limit of profit under the conditions then existing. It was not recognized that the bonanza deposits at the surface occurred where divisions in the vein, caused by immense 'horses' of included country rock, had re-united, and such junctions taking place in both horizontal and vertical planes had favored the concentration of ore.

The outcrop of the Guadalupe vein is remarkable for its prominence and its persistence. The hard quartz stands out like a masonry wall above the confining andesite, and can be followed from the town of La Cumbre de San Manuel, where it disappears under a capping of rhyolite, down the great ridge, or *cordon*, to the Bazonopa river, a distance of three and a half miles, the difference in elevation between these two points being 3,500 ft. It shows forth conspicuously on the canyon walls on both sides of the river in great wax-yellow zones, and disappears again toward the east under another capping of rhyolite. At short intervals there appear four other parallel veins of similar character in the canyon of the Bazonopa, measuring from 10 to 60 ft. in width. Off-shoots from this system of parallel veins traverse the country in all directions, many of these spur-veins having been worked by the Mexicans in a desultory fashion. One American company is today operating a small mine, known as El Pochi, three miles from La Cumbre, and the Premier Development Corporation of Mexico, Ltd., is making elaborate preparations for opening up the San Juan Nepomuceno mines a few miles to the northward. On the east side of the Bazonopa river, closely connected geologically with the Guadalupe vein, is a large low-grade copper property, with a heavy gossan, which has been much heralded as a promising mine and southwest of the Guadalupe mine is a strong vein carrying large quantities of zinc-blende, associated with galena and chalcocopyrite.

It is noticeable that the off-shoots from the great Guadalupe vein carry large quantities of copper and zinc, and also that, relatively to the other metalliferous minerals, zinc-blende abounds toward the westward, and chalcocopyrite toward the eastward, throughout the entire system of veins. The veins are all distinctly of the replacement type, occurring entirely in the older andesite and granite, in close association with later dikes of dark aphanitic andesite, and the deep erosion prior to the final outflows of rhyolite reveals these veins unaltered in width and mineralogical character to a depth of 3,500 ft. It is interesting to observe that the ancient topography, resulting from the erosion of the older andesite, diorite and granite of the region, has been practically restored on the same lines by erosion subsequent to the enormous outpouring of rhyolite which filled all the old valleys, and capped the whole with great lava steppes. It is evident that the shrinkage of the lava-fills in the ancient valleys must have opened lines of weakness through the overlying horizontal capping, which the drainage rapidly widened and deepened, until the canyons and *arroyos* were restored, only deeper and with more precipitous sides. In a few cases minor veins have been formed in the overlying rhyolite and rhyolite tuff, but all the known veins of importance occur in the ancient andesite, or associated with andesite dikes through granite, which latter first appears near the summit of the great ridge at La Cumbre de San Manuel, and becomes increasingly common from that point westward toward Bacubirito. A conspicuous feature of the veins in the granitic areas is an increase in the silver content of the ores.

Following the old trail westward, a remarkable occur-

rence of limestones and shales is first encountered near Valgame Dios, extending for many miles, faulted, distorted, and intruded by the granite and andesite, and overlaid by horizontal flows of rhyolite. These later eruptives form one extensive *mesa* at San Vicente on the east bank of the Sinaloa river, where the superincumbent lava-flows are 1,100 ft. deep, resting upon an exposed thickness of 400 ft. of confusedly distorted limestone and indurated shale. Numerous copper deposits, mostly in contact with limestone, have been discovered in this district, notably at Valgame Dios and Platano. Some of these deposits have great promise, and are well worthy of careful investigation. The ores are more basic than those in the Bazonopa valley, but contain smaller quantities of the precious metals.

The climate of this district is semi-tropical, and yet so tempered by the surrounding mountains that wheat and sugar cane, oranges, bananas, and apples, meet in the same fields and gardens. Platano is an especially fertile and delightful spot, with scenery of almost matchless beauty. The great peaks and ridges rising above it are well covered with oaks, *tepehuaje*, and other hard woods, while the Platano and Naranjo *arroyos* strike back within a few miles to the pine-clad slopes of the great Sierra. The *arroyos* yield abundant water, and only a few miles below is the Sinaloa river, in which a large permanent supply of water is available at all seasons. The region is ideal for mining, and the well-known existence of so many promising veins of copper and other metals gives occasion for surprise that American prospectors have paid so little attention to this field.

The prominent ridge of Ocorahui, rising to altitudes of from 3,500 to 7,000 ft., lies west of the Sinaloa river, causing it to make a long detour toward the north before it finds an outlet to the coastal plain. This magnificent range, possessing some local celebrity from the copper-gold mine of La Joya, is composed of a granitic core, with great intrusions of andesite on both the east and west flanks. On the western slope, in the Zapote *arroyo*, are seen multitudes of trap dikes, and where these have intruded through the granite they are usually accompanied by strong veins of black quartz, both in color and texture simulating the appearance of anthracite. A few grab samples from these veins casually gathered *en route*, revealed in all cases small amounts of gold, the highest assay being \$3.50 per ton.

There are persistent rumors of the occurrence of coal in the drainage basin of the Zapote *arroyo*, for which these black quartz veins may be responsible. On the other hand, however, there are large areas of stratified rocks in the valley, containing some shales which are distinctly bituminous. Near the Rancho del Padre, within a distance of three-fourths of a mile, a total vertical thickness of 310 ft. of these tilted sedimentaries was measured. Limestones are also abundant in the same basin, one series of strata yielding a fine-grained argillaceous limestone which would make a fair grade of natural cement. Very pure limestone and good clays, suitable for the manufacture of portland cement, are abundant in the vicinity of Rancho del Padre and Temuchino.

The thickness of the sedimentary rocks in this basin cannot readily be determined. They apparently represent the remnants of a great syncline, the major portions of which have been denuded. They are surrounded on all sides by andesite and granite and have been excessively faulted and crumpled, and in places shot through by dikes of dark basic eruptives. Between Temuchino and Bacubirito the sedimentaries have been largely covered by andesitic breccia and tuff, which also fill the broad basin of Bacubirito. At the latter city, which is certainly the most picturesque mountain town in the State of Sinaloa, a strong tributary, known as the Descubridora,

joins the Sinaloa. This stream is notable for its placers, from which a large output of gold has been derived in times past; the native washings still yield a considerable amount, conspicuous for very showy nuggets.

Low, in 'Technical Methods of Ore Analysis,' gives the following scheme for testing tungsten ores: "Treat 0.5 gram of the finely powdered ore in a small platinum dish with equal parts of strong hydrochloric and hydrofluoric acid. Digest on a water-bath until solution is complete, adding more of each acid from time to time if necessary. It may require from one to several hours to effect complete decomposition of the ore. Usually a perfect solution may be obtained. Finally evaporate to

tain the weight of tungsten, from which the percentage in the ore may be calculated."

At the recent session of the International Miner's Congress in Europe the report of the credential committee was to the effect that there are 708,200 miners in Great Britain, of whom 480,000 were organized, and had elected 14 members of the House of Commons. In France there are about 200,000 miners, and 150,000 are organized; they had two members in the French Parliament. In Belgium there are 135,000 miners, 65,000 of whom are organized, and they had two members in the Belgian Parliament. In Germany there are 600,000 miners, of whom 112,000 belong to the German Miners' Federation and 70,000

Fig. 1. Steel Structure in fore-bay supporting the three compressor-heads over each shaft. On the head-piece to the left a space is open wherein the pipe-head containing the small air-inlet tubes hanging on the derrick, just above, is to be placed.

about 15 c.c. with an excess of hydrochloric acid. A yellow precipitate of H_2WO_4 may separate during the final evaporation, owing to the expulsion of the hydrofluoric acid that holds it in solution. This will do no harm provided it can all be removed from the dish. Transfer the solution and any precipitate to a six-ounce flask, add 20 c.c. of strong hydrochloric acid and 8 c.c. of strong nitric acid. Boil down to about 10 c.c. This will expel any remaining hydrofluoric acid and precipitate the tungsten as tungsten acid— H_2WO_4 . Dilute with 50 c.c. of hot water and allow to simmer at a gentle heat for about half an hour, or until the tungstic acid has settled clear. Filter, wash well with hot water slightly acidulated with hydrochloric acid, and then dissolve the tungstic acid on the filter by pouring warm dilute ammonia over it using as little as possible and washing the filter with the same solution. Receive the solution in a weighed platinum dish. Evaporate the solution on a water-bath to dryness and then ignite the residue at red heat, cool and weigh as WO_3 . The cold residue should be bright canary color. Multiply the weight of the WO_3 by 0.793 to ob-

belong to the German Christian Miners' Federation. Austria has 135,000 miners, of whom 40,000 were organized in unions. The United States has 550,000 miners, 365,000 of whom belong to unions. It was therefore claimed that out of something like two and one-fourth million miners 1,282,000 were organized in trade unions, and had sent 116 delegates to the Congress.

ANY rock or ore which gives a decided reaction for tellurium should be assayed for gold and silver. Tellurium, however, is not always accompanied by gold. It forms combinations with other minerals, such as nickel, lead and mercury. Where any traces of gold and silver are found associated with tellurium, it would be well to seek in the vein for a richer pay-shoot. The geological conditions stated by the Sandy, Nevada, correspondent would usually be considered favorable to the occurrence of orebodies. The occurrence of numerous quartz crystals in the vein has no particular significance, unless it indicates the pockety nature of the vein, which it certainly does in some districts.

Hydraulic Air-Compression at the Victoria Mine.

Written for the MINING AND SCIENTIFIC PRESS
By C. H. TAYLOR.

In response to a request from the editor of this journal I take pleasure in presenting an account of the hydraulic air-compressor I have just completed for the Victoria Copper Mining Co., near Rockland, Michigan, and a copy of the report on the efficiency test made by Professors Sperr and Hood of the Michigan College of Mines.

The capacity of the compressor in free air is 36,000 cu. ft. per min., compressing it to a pressure of 117 lb. per sq. in., or over 5,000 h.p. The water supplying this compressor is taken from the Ontonagon river. A concrete dam 500 ft. long and 18 ft. high crosses the river at a point 4,000 ft. up-stream from the compressor, and a canal having a cross-sectional area of 350 sq. ft. leads from the dam to the forebay of the compressor, giving a working head of 71 feet.

The compressor has three intake shafts which are sunk to a depth of 330 ft., connecting them with the air-chamber or separating-tunnel. These shafts are sunk in sandstone and concreted their entire length, leaving a smooth interior of 5 ft. diam. At their lower end, a tapering pipe is cemented in, its lower end having a diameter of 7 ft. 4 in., while the upper end is of the same size as the shaft. These pipes extend downward into the tunnel 16 ft. and up into the concrete 14 ft. The flash-light view (Fig. 5) illustrates this construction.

The tunnel or separating chamber is 57 ft. wide and 22 ft. high where the intake shafts enter, and it tapers to 18 ft. wide and 25 ft. high at a distance of 50 ft.; from this point it continues at the same height for 281 ft. further, when it drops vertically to 10 ft. high and connects with the discharge-shaft, which has a cross-sectional area of

288 sq. ft. A sectional view of the compressor and excavation is shown in Fig. 4.

Fig. 2 is a flash-light photograph of the discharge end of the tunnel, showing the 24-in. air-main with a protecting strainer where it emerges into the air-chamber in the upper corner. The pipe reaching downward is the escape or blow-off, which prevents the water being pressed below the saucer-shaped foot-piece; the air escapes through this pipe as soon as the saucer end is uncovered, filling and sealing it up again as soon as the water covers it. Fig. 1 is the steel structure over the intake shaft, supporting the head-pieces.

Fig. 3 gives a fair idea of the cold produced by the expanding air as it comes from the stamp-engine. You will notice the exhaust pipe is all covered with ice which has accumulated on the outside from the moisture condensing and freezing to it during warm weather. The temperature of the exhaust is from 40 to 50 degrees below zero.

The principle of the compressor is simple: The water is drawn in between two conical castings, having an adjustable space or opening; between these two castings are placed 1,800 three-eighth in. standard pipes, the arrangement of

Fig. 2. Flash-light view showing outlet end of air-separating chambers. In the upper corner the end of the 24-in. air-main is shown with a strainer at its end; leading down with a saucer piece on its end is the 12-in. blow-off pipe. The low tunnel at the bottom is the water escape which connects with a tail-race shaft.

which is shown in Fig. 1. The partial vacuum caused by the descent of the water draws the air through the small pipes which take air through the 7-in. vertical pipes in the headers, whose upper ends open to the atmosphere.

With the proper setting of the head, the air produces a vibrating sound resembling the running of a pair of iron gears at high speed. This vibration is caused by the bubbles of air separating from the ends of the small tubes; these bubbles are disseminated through the whole column of descending water and forced down to the end of the compressor-shaft, striking the conical spreaders shown in Fig. 5, which scatters the water into the

separating chamber. On its course to the discharge shaft, it rises to the surface of the water, accumulating there, and displacing the water until it is forced down to the saucer-shaped end of the blow-off pipe, when the air escapes, preventing the water from being forced down any further. If the air is drawn through the 24-in. air-main to the full capacity of the compressor, the blow-off becomes inactive. The separated water passes on through the lower tunnel (shown in Fig. 5) and up the incline shaft to the tail-race. The pressure of the air is equal to the vertical height of the water in the discharge shaft only. The natural water-head controls the volume of air to the extent of the volume of water available together with the dimensions of the compressor. A compressor of this kind can be constructed to give any pressure and any horsepower, depending upon the natural head and the quantity of water.

The object of sinking three separate compressor-shafts in this particular case is due to the fact that during some years the dry spell lasts so long that the water available from the river decreases in volume so that there would be only sufficient to supply one head and run it efficiently. Each head will work at a high efficiency varying from 1,000 to 1,750 h.p. There would be a marked drop in the efficiency if the water should drop below developing 1,000 h.p. With the three shafts, a high efficiency can be obtained all the time.

The head-piece is constructed so that it can be raised or lowered either by hand or by admitting air under the inverted tank surrounding it, its connection with the shaft being a telescope-pipe. It is also arranged to work automatically, if desired, during a scarcity of water. This is accomplished by a small blow-off pipe, shown in Fig. 1, which runs up the centre shaft and is concreted in its side. The foot of this blow-off is set at an elevation of 13 in. above the main blow-off and is controlled by a valve at the surface. As soon as the air accumulates in the chamber and forces the water down below its lower end, it escapes up this pipe (when the valve at surface is

left open), displacing the water in the inverted tank around the head-piece and raising it above the water-level; the water then remains there as long as it continues to blow. Referring to Fig. 3, a valve will be seen on the side of the tank; this valve is left slightly open, so as to allow the air to escape, causing the head to settle down as soon as the small blow-off ceases to supply the necessary air to overcome the air escaping through this valve.

With the present development of the mine one of the

three heads supplies a third more air than is required. The machinery now in operation and driven by the air thus compressed includes:

One Webster, Camp & Lane direct-connected Corliss hoisting engine, two cylinders 20 by 48 in., having a hoisting speed of 1,500 ft. per min. from a depth of 3,000 ft. with a load of six tons.

One rock-house engine, cylinder 14 by 12 in. running 125 r.p.m. and driving two large crushers.

One machine-shop engine of 14 horsepower.

One small engine in blacksmith shop, 8 horsepower.

One drill sharpening machine, one air-hammer and three forge-fires.

Seven 150 and 200-gal. pumps, raising water out of the mine, which is 2,200 ft. deep.

Ten No. 3 Rand drills.

One 13 by 24-in. double-cylinder winding engine hauling cars to and from the mill, a distance of 4,000 ft., with a capacity of 400 to 500 tons per day.

One Ball stamp-head, cylinder 18 by 26 in., capacity from 350 to 500 tons. This head works with a wide open throttle and strikes 100 blows per minute.

One 10 by 12-in. mill-engine running 190 r.p.m. and driving 56 large jigs, 6 Card concentrating tables and the valve-gear of the stamp-cylinder.

One 12 by 16 in. sawmill-engine.

In addition there are several air-lifts and other sundry applications. This plant was started on March 9 and has continued in operation constantly; from all appearances it can continue to do so for the next fifty years.

The advantages of this compressor are:

Fig. 3. Three-ton stamp direct-driven by piston-cylinder 18 by 26 in., making 100 blows per min. The outside of the exhaust is covered with ice caused by the condensation of moisture from the surrounding atmosphere. This stamp is driven by air from the hydraulic air-compressor.

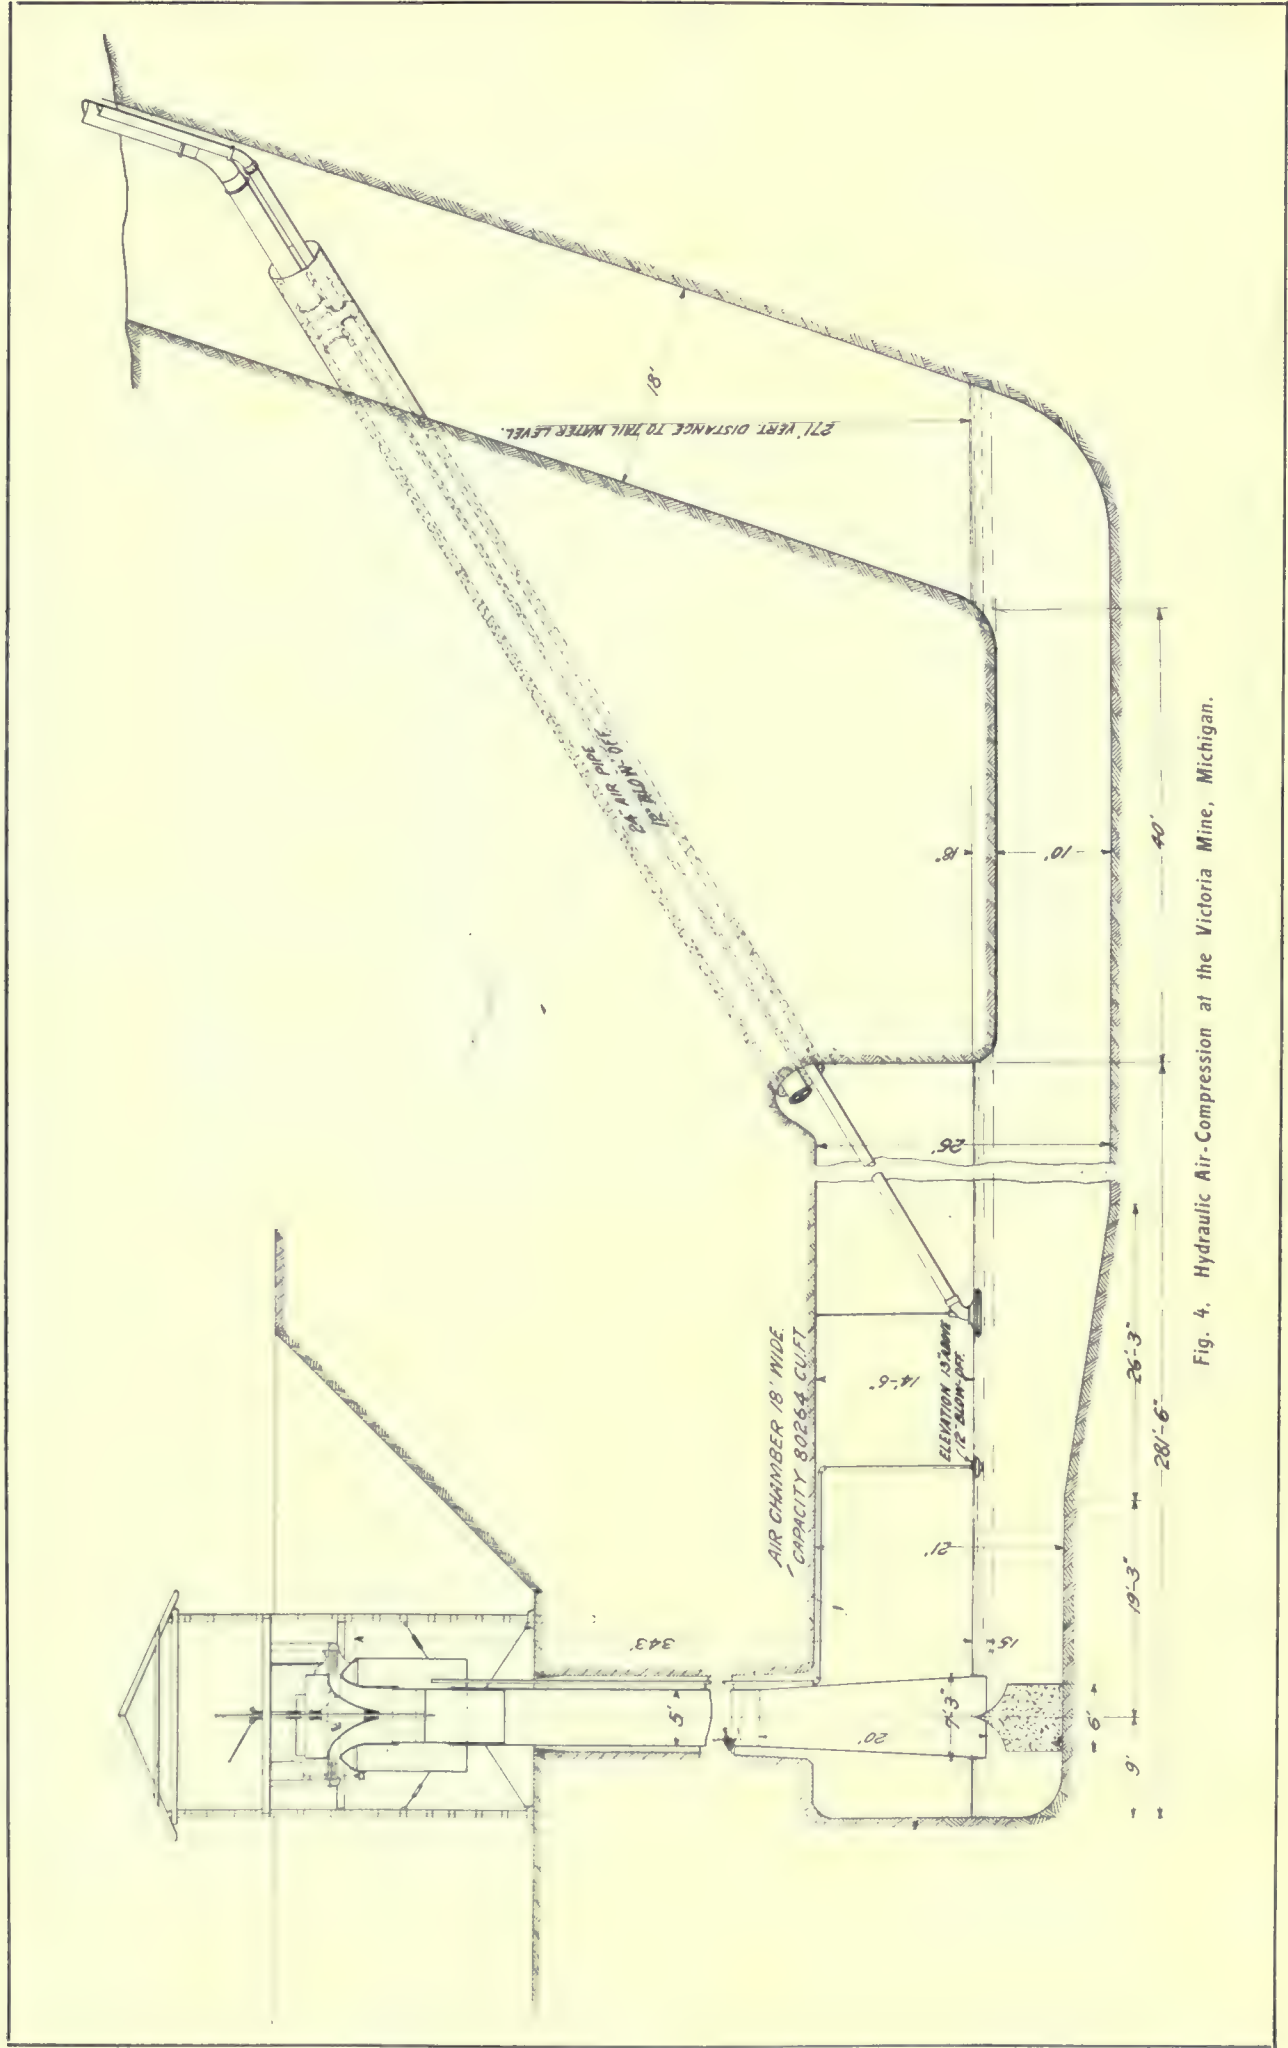

Fig. 4. Hydraulic Air-Compression at the Victoria Mine, Michigan.

- 1. It requires little, or no, attention.
- 2. There are no moving parts liable to derangement.
- 3. The air is compressed isothermally, therefore it does not carry any moisture, to be condensed in the air-mains and freeze in the exhaust of the pumps, drills, hoisting and other engines.
- 4. The air is perfectly pure, there is no smell of evaporated or burnt oil in the air used for ventilation.
- 5. The maintenance is little or nothing, and its durability is unlimited.
- 6. The high efficiency obtained from the actual power of the water.
- 7. It produces a power that can easily be doubled with the smallest consumption of fuel, the increased power being obtained with less than half a pound of coal per h.p. hour.

8. A power that has a storage capacity so that from 25 to 50 % more power can be drawn from it for a short period than is being compressed, without affecting the pressure. In the present plant, the storage is over 80,000 cu. ft. of air at a pressure of 117 lb. sufficient to run 1,000 h.p. extra nearly two hours.

head to be tested was enclosed in a tight chamber and the velocity of the air, admitted through a duct two feet square, was measured by an anemometer. Within the canal leading to the penstock a flume was placed of approximately seventy square feet sectional area and water velocities across the whole section were determined by a current meter. The observations were taken May 28 and 29 by Professor F. W. Sperr.

Two tests at near the maximum capacity show the exceptionally high efficiency of 82 %. The separation of the air from the water seems to be complete.

Respectfully submitted,
(Signed) F. W. SPERR,
O. P. HOOD.

Fig. 5. Flash-light view of the three steel tubes, which extend through roof of air-separating chamber and are connected in lower end of compressor shaft. The photograph also shows the division wall between the tubes, placed there to prevent the water of one compressor from interfering with the other.

THE only restriction placed by the Russian government on the private production of gold in Siberia is the provision that the gold must not be taken out of the country in its rough state. If the gold-miner sells his gold to the Government laboratory in Tomsk, or Irkutsk, he receives full value for it, both for the gold and the included silver. The payment is made at once in the form of a draft on

Houghton, Michigan, June 9, 1906.
Mr. Thomas Hooper, Superintendent Victoria Mine, Rockland, Michigan.

Dear Sir—In accordance with your request of May 9 observations have been made to determine the efficiency of the Taylor hydraulic air compressor installed at the Victoria mine. The results of three tests are as follows:

AIR MEASUREMENTS.					
Sq. ft.	Vel. per sec.	Cu. ft. per min.	Absolute pressures.		Horsepower.
			Free.	Comp.	
4	44.09	10,580	14	128	1,430
4	49.74	11,930	14	128	1,623
4	38.50	9,238	14	128	1,248

WATER MEASUREMENTS.					
Flume area.	Vel. per sec.	Cu. ft. per min.	Head ft.	Horsepower.	Efficiency. Per cent.
71.75	3.033	13,057	70.5	1,741	82.17
67.03	3.684	14,820	70.0	1,961	82.27
72.16	2.936	12,710	70.6	1,700	73.50

Three similar heads have been installed and measurements were made of the air and water supplied to the middle head, the other two heads not running. The

the Government bank, which may be cashed in standard Russian gold coin, if desired. The tax of three per cent which formerly existed on gold mined in western Siberia has now been removed, and the only nominal charges are for transportation and coinage. The operator must transport his gold to the railway at his own risk, but from the railway station it is transported at the risk of the Government.

THE position of undercurrents in a placer-mining plant should be considered with care, for unless they are properly constructed and placed in the best position they will prove of little usefulness. A grizzly of steel bars, set one inch apart, must be placed in the sluice-line one inch lower than the tops of the riffle-blocks or stone pavement in the sluice. The fine material passes through, onto the undercurrent, which has a grade at right angles to the sluice. It relieves the sluice of much fine material.

THE surest proof of the truth of scientific conclusions is the fact of their *not* being original so far as *one* person is concerned, and of their having become manifest to more than one mind, either about the same time, or successively, without communication.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

ROTARY ELECTRIC FURNACE.—No. 825,058; Woolsey M. Johnson, Iola, Kansas.

A rotatable electric furnace comprising a chamber composed of separate sections provided with refractory linings, a resistance conductor for heating said chamber, and means for rotating said furnace.

ORE SEPARATOR.—No. 825,758; Samuel J. Rogers, Bingham Canyon, Utah.

An ore-concentrating apparatus, comprising a frame having side members, an endless traveling belt supported by the frame, a pair of oppositely arranged brackets carried by the side members of the frame, adjustable guides for the edges of the upper run of the belt carried by said brackets and adjustable guides for the edges of the lower run of the belt carried by the side members of the frame.

CONTINUOUSLY OPERATING RETORT FURNACE.—No. 825,536; Richard C. Hills, Denver, Colorado.

A retort furnace provided with two banks or series of horizontally disposed retorts located on opposite sides of the central part of the furnace in which are located downwardly extending exhaust flues communicating with the stack, and combustion flues interposed between the retorts and extending the entire length of both banks of retorts on one side of the latter, passing around the end of one retort on one side of the furnace and extending in the reverse direction on the opposite side of one retort and finally communicating with the said downwardly extending exhaust flues.

MINE HOIST.—No. 825,477; Austin B. Paige, Iowa Falls, Iowa.

In a mine hoist, a shaft having a drum thereon, bearings for the said shaft, a clutch member on the end of said shaft, a second shaft having balance-wheel thereon, bearings for

said second shaft, a clutch member on said shaft, a sheave on the second shaft, a second sheave mounted on a shaft in suitable bearings, laterally removed from the first sheave, a rope for embracing the sheaves, means for rotating the said second sheave, means for moving the clutch members into and out of engagement, and a brake for controlling the speed of the first-mentioned shaft.

ORE CRUSHER.—No. 825,699; Isaac N. Bonsal, Oronogo, Missouri.

In a crushing machine of the character described, the combination of an open crusher-bed, a stationary jaw fixed within one end of the bed, a movable jaw working between the sides of the bed in co-operative relation with the stationary jaw, wear-plates secured to the inner walls of the bed between the two jaws, the inner walls of the bed being provided with open-ended recesses at the backs of the wear-plates, backing-plates fitted within the recesses, and removable fastenings piercing the sides of the bed and engaging in backing-plates.

MAGNETIC ORE SEPARATOR.—No. 825,672; Richard R. Moffatt, Brooklyn, New York.

In a magnetic ore separator, the combination of upper and lower poles of opposite polarity, rectilinearly moving feed and separating conveyors intersecting each other in the interpolar space and adjustable means whereby the feed conveyor is abruptly brought into closer proximity to the upper pole at one point than at a preceding point, whereby the strongly magnetic particles are separated at one point on the separating conveyor and the feebly magnetic particles are separated at another point on the same separating conveyor.

New Copper-Matting Furnace.

The accompanying illustration represents the latest type of copper-matting blast-furnace recently built for the New World Smelting Co., of Seattle, by the Colorado Iron Works Co., of Denver. This furnace, which is now being installed at the mines near Livingston, Montana, has some new features, including angle-inlet tuyeres and combination trap-spout. There are two tiers of steel-plate water-jackets, the

Latest Type Copper-Matting Blast-Furnace.

upper one being supported independently of any other part of furnace by a steel I-beam frame carried upon brackets on the corner columns. The tuyeres shown are the Colorado Iron Works Co.'s latest type, the blast inlet entering at an angle of 45 deg., thus avoiding the sharp corner and excessive friction. The trap-spout is made of cast-iron plates, bolted together, lined inside with magnesite. The overflow end is fitted with a water-jacketed copper tip, which resists the greatest cutting effect of the matte. This furnace is 42 by 120 in. at the tuyeres and has a capacity of about 150 tons per 24 hours.

ACCORDING to the Department of Commerce and Labor \$35,000,000 worth of diamonds were imported into the United States in the fiscal year 1906. No article shows greater fluctuation in the imports than diamonds. In 1906 the total, as stated, was \$35,000,000; in 1904, two years earlier, only \$19,000,000; in 1903, \$26,000,000; in 1900 but \$12,000,000; in 1897 less than \$2,000,000, and in 1893 about \$15,000,000. About \$10,500,000 worth of diamonds imported in 1906 were uncut, to be prepared for use by the diamond-cutting establishments of the United States, while over \$24,000,000 worth were cut but not set.

'ROUGH-CAST' is an external plastering in which small sharp stones are mixed, and which, when wet, is forcibly thrown or cast from a trowel against the wall, to which it forms a coating of pleasing appearance. When well executed the work is quite durable. The mortar should have some cement mixed with it.

WHERE the mine-water is acid it corrodes wrought-iron or steel pipes, so that some other metal must be used, as bronze or copper, or again, where the pressure is not great, even wire-wound wood pipes. For higher pressures, iron pipes lined with red-wood soaked in asphalt have given good results.

Trade Treatises.

THE SMOOTH-ON Co., of 572 Communipaw avenue, Jersey City, N. J., has issued the fifth edition of 'The Instruction Book,' telling how to use the iron cement—smooth-on.

STURTEVANT ENGINEERING Co., of Hyde Park, Mass., has issued Bulletin No. 137, describing the Flinn steam trap, a device to drain water, due to condensation, from steam-pipes, gauges, coils, cylinders, etc.

THE DENVER ENGINEERING WORKS has published Bulletin No. 1,027 on tube-mills, illustrated by half-tones and line-drawings, with descriptive text explaining the method of their operation and results accomplished, and working costs.

'Some Details as to Smelting Practice and Equipment,' is the title of catalogue No. 12 of the COLORADO IRON WORKS Co., of Denver, being the fifth revised edition of this interesting and valuable publication. The chapters on hot-blast smelting and copper-matting and pyritic-smelting are valuable. The book, containing 157 pages, is handsomely illustrated and is of value to all who contemplate the purchase of a smelting plant.

THE WELLMAN-SEEVER-MORGAN Co., of Cleveland, Ohio, has issued several new bulletins and circulars. Bulletin M-104 describes the copper-converters and equipment made by it; Bulletin M-103 is on stamp-mills and equipment; circular H. O.-9 describes and illustrates first motion winding engines with Corliss non-detaching valve gear, made by this company; Bulletin M-101 is descriptive of both the spring and rigid types of Akron crushing-rolls, and Bulletin M-102 is on the copper blast-furnace.

THE JAMES LEFFEL & Co., Springfield, Ohio, has issued a handsome and complete new catalogue of 52 pages, illustrating and describing its line of steam-engines and boilers. The details of construction are plainly shown and fully explained, and the catalogue is one that should be in the hands of any prospective purchaser of work in the steam-power line. A copy will be furnished free to prospective buyers, stating their wants, and addressing the company as above. In writing please request Catalogue "O."

Commercial Paragraphs.

TWO LANE SLOW SPEED MILLS have been purchased by the Wire Patch Gold Co. at Breckenridge, Colo., to crush iron pyrite to 80-mesh, and amalgamate the gold therein.

THE COLUMBIA ENGINEERING WORKS, of Portland, Ore., announces that it is prepared to give \$100 cash bonus to the individual who will find a pure silica sharp sand, suitable for molding in steel foundry practice, and in sufficiently close proximity to the railroad that it can be delivered to Portland, Ore., at a price of \$4 per ton, including freight.

THE TRAYLOR ENGINEERING Co. and Traylor Manufacturing & Construction Co. have been consolidated into one corporation, under the name of the Traylor Engineering Co. The consolidation is stated to be the result of the increase of the business of the Traylor Engineering Co., which made it desirable to combine the two concerns in order to simplify and expedite the conduct of their business. Under the old arrangement the Traylor Engineering Co. was the active concern dealing with the public while the Traylor Mfg. & Construction Co. owned the works at Allentown, Pa., and did the manufacturing under contract for the other.

At a meeting of the board of directors of THE COMPRESSED AIR MACHINERY Co., of San Francisco, the following officers were elected: P. H. Reardon, president; J. M. O'Brien, vice president; Eldredge Green, secretary; Crocker-Woolworth National Bank of San Francisco, treasurer. The directors of the company are: C. E. Green, manager of the Crocker Estate Co.; Wellington Gregg, Jr., cashier of the Crocker-Woolworth National Bank of San Francisco; J. M. O'Brien, president of the Humboldt Transit Co. and The Sultana Gold Mining Co.; J. E. Green, president of The Parkside Realty Co. of San Francisco, and P. H. Reardon, who retains the management.

Editorial.

THOSE MEMBERS of the American Institute of Mining Engineers who attended the meeting in England must have had an enjoyable experience, for they were entertained hospitably, and even magnificently. Captain R. W. Hunt, the president, and Dr. R. W. Raymond, the secretary, made excellent speeches on several occasions. Six members were presented to King Edward.

THE CALIFORNIA MINERS' ASSOCIATION suffered the loss of its annual transactions, which were in the printer's hands when the earthquake-fire destroyed so much that was valuable. However, like all other Californians, the president, Mr. Alfonso A. Tregidgo, set to work at once to repair the loss, and we are glad to learn that the volume of transactions is again in course of being printed. The association has secured an office at 1428 Sutter St., and Mr. E. J. Ensign is acting as its secretary. The annual convention is to take place at San Francisco in November next.

THE IRON AND STEEL INSTITUTE, by its Council, has voted to give the Bessemer medal to King Edward, as was done several years ago to Queen Victoria. The Bessemer medal is one established to commemorate a great metallurgist and an epoch-making invention; it is given each year to the man who by his metallurgical research has best advanced the iron and steel industry. Nothing could emphasize the different notion of what is befitting—in other words, the diverse taste of cultured men—in England and America than this bestowal of the Bessemer medal on the King. He is worthy of all honor and of the affections of his people, but gold medals for metallurgical research seem to us to belong to someone else. It would be only fair if the King should graciously signify his intention of bestowing the title of Poet Laureate on each member of the Council.

IN THE current issue of *The Mining Investor* there is a long article entitled 'The Comstock in 1876'; it is an interesting article, in fact, a mighty good article, and it does *The Investor* credit. According to a conspicuous note it is "reprinted by permission from *The Engineering and Mining Journal*." Well, the article is really a good one, and would be something for *The Engineering and Mining Journal* to be proud of. But it was not published by our junior at New York; it was written by Mr. W. H. Storms, and appeared in the MINING AND SCIENTIFIC PRESS of February 24, 1906. We are reminded of a duck story. It appears that an alleged sportsman saw some ducks in a quiet pond and asked permission of a man, whom he supposed to be the owner of the property, to shoot those ducks; which he did; and then another man, the real owner, came out with a gun and things happened. Meanwhile the man to whom the sportsman gave

\$5 for permission to shoot, was far away. Moral: Get permission from the right fellow.

UNDER SPECIAL CORRESPONDENCE we publish this week a letter from Redruth. The letter makes no particular pretensions, but it is interesting as coming from an old mining centre. Redruth is not only that; it is more; it has been the cradle of mining to many generations of men. What London is to the financier, Paris to the dressmaker, New York to the hotel-keeper, and Boston to the really intellectual, that Redruth is to those who use the pick and gad. One of the sulphides of copper is called 'redruthite,' to emphasize the fact that at one time this Cornish town did the business of a great copper industry. But even mines peter out. Redruth lost her importance as the workings penetrated through the slate into the granite, the copper giving out as the tin came in, but not as richly. Nevertheless, with that dogged perseverance that makes the Cousin Jack a great miner, the local shareholders held on, deepening their shafts and extending their explorations underground until a depth of 3,000 feet was attained. Lately there has been a revival, for the price of tin has risen to an unprecedented figure and one or two discoveries, particularly in that famous old mine, Dolcoath, have stimulated the interest of the financial world at London. So Redruth, overlooked by Carn Brea, and looking toward the tempestuous shore at Porthtowan, is again in the minds of mining men, from Alaska to Patagonia, from Korea to South Africa. Many a Cornishman having his 'croust' in a quiet cross-cut, munching the 'pasty' that has sustained the energy of generations of 'tributers,' will speak of the old town and revive the memories of a youth in the West Country.

Mining at Its Best.

The annual report of the Wolverine Copper Mining Company affords an example of good clean business, the kind that lifts mining from a vulgar gamble to a great industry. It is shown that 355,339 tons of ore were treated for a yield of 9,681,706 pounds of refined copper, which was marketed at an average of 17.17 cents per pound. The ore gave 28.32 pounds of refined copper per ton, equivalent to 1.416 per cent; the cost at the mine amounted to 5.47 cents, and the cost of smelting, freight, and marketing at New York was 1.03 cents, so that 6.5 cents per pound represents the total working expenditure; to this, 0.26 cent is to be added for construction. Thus the profit was 10.41 cents per pound, or 60 per cent of the gross yield. This is splendid work, the excellence of which is emphasized by the further statement that the total working cost was only \$1.49, on an ore yielding \$4.04 per ton. What the gross value of the ore was, it is difficult to say; for the loss in milling is not known accurately. The best work in the Lake Superior stamp-mills represents an extraction of 80 to 85 per cent; so that the crude ore was worth about \$5 per ton.

Apart from the highly profitable result of operations as disclosed in the report, the document is a model in its brevity, conciseness, and completeness of information.

To John Stanton, the founder of the company, whose useful career closed a few months ago, is due the high character of the management at this, and several other mines, in the copper country of Michigan. No finer legacy can be left by a man to his sons, and to other men's sons; than this—a continuity of honorable business practice.

The Transvaal Constitution.

We have nothing to do with politics, but we take a keen interest in the industrial welfare of the great mining regions of the world; this is our excuse for referring to a political matter of paramount interest. From telegraphic despatches we learn that the statement of the British Government's intentions in regard to the new Constitution for the Transvaal has caused much uneasiness in that department of the London Stock Exchange devoted to 'Kaffirs,' or South African mining shares. It is the general expectation that the manhood suffrage to be granted to the Colony will give the British residents a slight preponderance over the Boers in the new Parliament of the Transvaal, but all of the majority will not necessarily be allied to the mine-owners, so that the result of legislation is uncertain. Our Johannesburg correspondent, in his letter published in our last issue, expresses the irritation felt at the actions of the Liberal Government and he emphasizes the impossibility of any revival in mining speculation until the labor problem receives definite solution. The recruiting for coolies in China will cease on November 30 and it will be open for the new legislature in the Transvaal to pass another labor ordinance. But the British Government reserves the right to veto laws that impose any disability on immigrants, so that coolies appear likely to be barred, and on the other hand the African States, like those of Australia, will oppose any step enabling the Chinaman to enter the country as a free man.

Another awkward matter awaits solution. By the Vereeniging conference, at the close of the war, it was agreed as one of the terms of peace that the right to vote should be withheld from the native and colored population in the Transvaal. It is notorious that many of the Boers are partly of African descent and among them this stain is not considered as disgraceful as among Europeans. Yet it will be difficult to make distinctions. If the right to vote had been conditioned on a property qualification, however small, it would have been possible to avoid this dilemma. As it is, with self-government based upon manhood suffrage without proportional representation, it is quite on the cards that the Boers may get the reins of power, an event that would revive all the knotty problems cut by the sword. The Boers are in a minority of 20,000 on a total of 90,000, yet, by reason of the distribution of representatives, there is a chance that they may get a majority of two or three in the new Parliament. The history of South Africa has been a record of great blunders. To those at a distance it would seem that the British Government has incurred the unnecessary risk of another political tangle fatal to the peace and prosperity of the Transvaal. No wonder the Kaffir market is tremulous.

By the Way.

REFERRING TO the question of Chinese labor on the Rand and its bearing on the future of the gold mining industry in the Transvaal, we quote from a dispatch to the British Foreign Office, sent by Lord Selborne, the Commissioner to South Africa. He says:

The African supply of labor, even including that from Portuguese East Africa, has long been insufficient to meet the ever-growing demand of the Transvaal. And the more the general prosperity of the Transvaal increases the less does the native labor supply suffice to meet its requirements.

It was this dearth of native labor which led to the introduction of Chinese labor to supplement the deficiency of native labor for the mines. And here I would respectfully protest against the view that the importation of Chinese coolies was only intended to bring the mining industry back to the position which it held before the war. That was a position from which, so far as can be judged by all the available evidence, it could never have advanced if it had been wholly dependent upon the native labor supply.

It can hardly be repeated too often that the existing industrial organization, to say nothing of the existing machinery of government of the Transvaal, could not be justified if the position of the gold mining industry, at the highest point to which it has hitherto attained, is to be taken as its permanent high-water mark.

Unless this expansion is allowed to proceed regularly and without any artificial check, both Government and industry will find themselves confronted with a serious crisis, the least effect of which will be to curtail greatly the sphere of usefulness of the Government and to close down many of the works of the industry.

This deplorable state of things would arise from the fact that the mining companies, in anticipation of the regular supply of labor which they require, have embarked on an enormous expenditure, in the way of development work, and of enlarging their sphere of mining operations, the whole of which expenditure would be thrown away if the regular supply of labor upon which they have reckoned were to be checked. I am not yet in a position to state with any accuracy what this expenditure amounts to, or what may be estimated as being the ultimate effects of the loss of it.

But I will give, as an instance of how the sudden curtailment of the labor supply would affect the mining industry, the following figures, which have been furnished to me by the Chamber of Mines: Of the Chinese coolies, for whose importation licenses have already been issued, but who have not yet arrived in this country, 11,700 have been ordered for the Consolidated Gold Fields group, the Eckstein group, the East Rand group, and the General Mining & Finance group. In anticipation of the arrival of these 11,700 coolies, the four groups which I have named have actually incurred or are on the point of giving orders incurring an expenditure amounting to not less than £2,000,000 for machinery and plant, and for the erection of compounds for Chinese and quarters for married and single white workmen.

You will notice that throughout the foregoing I have been dealing with the gold mining industry only. I have said nothing about the labor supply which may be required in the future to develop the other mineral resources of the Transvaal, in the shape of coal, tin, copper, or asbestos. Information is not yet available which would enable me to speak with certainty as to what the potentialities of the Transvaal are in the way of tin or asbestos, but I am quite sure that they are great. In addition, the Premier diamond mine has now reached a stage of development at which an increase in its supply

of labor, and a large increase, is urgently required. It is worth while here to mention that the governor of Cape Colony informs me that the Kimberley diamond mines are short by several thousands of the number of native laborers they require. I understand also that Natal still requires more Indian coolies for agricultural purposes. This shows that this deficiency of labor for industrial and agricultural development is universal throughout South Africa. Agriculture, indeed, cries out everywhere for labor, and will find it even harder to satisfy its requirements than it does at present if the mines, through the stoppage of their Chinese labor supply, are driven to strain every nerve to draw labor from agriculture to mining.

Everywhere, in the Orange River Colony and Transvaal alike, the farmers ask me insistently for more labor, and already several of them have formally asked leave to import coolies under a system of indenture as in Natal.

SPEAKING of scientific research, Mr. Charles W. Eliot, president of Harvard University, said: The public needs to obtain a clearer idea of scientific research, of its objects and results, and of the character and capacity of the men who devote themselves to it. The public has also been long interested in the inventor's resourceful and persevering habit of mind—the inventor who is trying to make some new application of acquired knowledge, or to discover a new fact or principle which can be put to commercial use. But scientific research is somewhat different from these other kinds of research. It has deep roots in the past; but its object is never to demonstrate merely what has been done or said, or to obtain a monopolistic profit. Invariably its object is to extend the boundaries of knowledge, and to win new power over nature. It is not chiefly concerned to enlarge records of the past, or to make them more accurate, but rather to use all the powers the past has conferred on the human spirit to win new power. The past gives the scientific investigator his lever and the present his fulcrum; but his work is to take effect on the future, and is to give him or his successors a stronger lever and a better placed fulcrum. As a rule, scientific research is carried on with no public observation, and as silently as nature elaborates and throws out the mantling verdure of spring; but in a country which has already reaped great benefits from the endowment of institutions of education and charity by public-spirited persons, it is fitting that the beneficent work of the scientific investigator should be accurately described, and commended to the favor of an enlightened public opinion.

Let us first consider what mental habits and powers the scientific investigator needs to have acquired and to keep in exercise, or in other words what sort of a mind the investigator ought to have. In the first place, he needs the faculty and the habit of determining and grasping facts, and then verifying and digesting them. He must next be capable of conceiving hypotheses which will connect his facts, or explanations that will group them or arrange them in a series. These hypotheses or explanations will come to him as results of reflection or of imaginative scheming; in the common phrase, ideas will occur to him. A preconceived idea may be a great power in experimental researches; but the inquirer must have the habit of pursuing to verification or disproof all such ideas. He must test them by new experiments contrived for that purpose. He must exhaust all the adverse hypotheses which come to his mind. He must always keep in the road that leads to truth, although he does not know just where the truth lies.

If through the play of his imagination he gets off the right road, his rigorous experimentation must bring him back to the safe path of the inductive method.

Special Correspondence.

REDRUTH, Cornwall, August 5.

The mines now in operation in the county represent but a small proportion of those working 40 or 50 years ago. Their principal product at that time was copper ore, but of the mines that extended from east to west of the county, none are now working exclusively for that metal. Tin has been for many years the only product of importance (excepting a little lead and other ores) and generally, but not always, it has succeeded copper in depth on the lodes, as they penetrated the granite formation from the overlying clay-slate (killas), especially in the western part of the county.

The present field of operation is confined chiefly to the mines situated around the base of Carn Brea, between the towns of Redruth and Camborne; these mines are considered deep, the present workings being from 1,000 to 3,000 ft. below the surface. The lodes, although fully maintaining their width, have not, for many years, been rich, the tenor of the ore varying from 30 to 40 lb. of tin oxide per ton of ore extracted; there has been also a notable absence of rich runs or columns of ore-ground with but few exceptions, and this, together with increased expenses, has, at moderate prices for tin, rendered working generally very slightly remunerative. Very fortunately the great advance in the price of the metal has, for the time being, put new life and energy in the working of existing mines, enabling them to work profitably and to push forward exploratory works, which for lack of means had been neglected or carried out on too small a scale. The advance in the price of tin has had the effect of opening up, in some cases, old mines, or parts of abandoned sets considered under present conditions to present good chances of success; among these may be named Condurrow, near Camborne and Wheal Vor to the west of that locality. It is, however, a notable fact that no new discovery, apart from known runs of lodes extensively worked, has been made.

Quite a new feature in Cornish mining is the successful application of electricity as motive power, it being applied at the Tywarnhaile mines in the Porthtowan district in re-opening these extensive copper mines. There does not appear to be much outside capital coming into the county notwithstanding that good profits are now being made in some of the old mines, the famous old Dolcoath having just announced a dividend of 15% on the last half year's operations. The main reason is that the formation of companies with moderate capital, mainly to be spent on the mines, does not present sufficient opportunities for stock exchange operations.

CALUMET, Michigan, August 18.

A drill cross-section of the Keweenaw Copper Co.'s lands, near the Mandan and Resolute properties, has been completed, and the diamond-drill work will now be devoted to what is known as the Empire tract. A shaft on the old Medora property, sunk in what is called the Medora vein, has been cleaned out, and the showing is excellent, the rock being of a good grade for stamping. The lode also contains some heavy copper. This formation also traverses the Keweenaw Co.'s lands for nearly four miles, so there is room for a large mine if the copper is there in paying quantity. The Medora lode parallels the Greenstone bluff at a distance of 800 ft., and 900 ft. further south is situated the Montreal river amygdaloid, which is giving promise on the Calumet & Hecla's Delaware property, where three shafts are in operation.

The Home office of the Lake Superior & Arizona Mining & Smelting Co., in Calumet, has a telegram from the

superintendent, A. C. Sieboth, at the mine, near Superior, Arizona, to the effect that the sulphide zone has been entered, which had long been searched for. In the upper levels there are large areas of good oxide ore blocked out, but it was the desire of the management to find the sulphide before starting work on a smelter. If it is proved that the sulphide zone which has been entered is permanent, the company will erect a smelter and build a tram to connect the mine with the railroad, 25 miles distant.

The site for the vertical shaft that the Hancock Consolidated Mining Co. intends to sink, has not yet been decided upon. The purchase of the surface rights of the Anthony farm, comprising 200 acres, beneath which the Hancock Co. already owned the mineral rights, simplifies the situation. The vertical shaft will reach the Pewabic and other lodes. John L. Harris, superintendent, has engaged John Peterson as head mining captain, in which capacity he was formerly employed at the Wisona for a number of years. Charles W. McDougal is chief engineer. He was formerly on the engineering staff of the Quincy Co. Fred Schubert, who also had experience at the Quincy, is surface and construction engineer for the Hancock. There have been several railroad surveys made to determine the most advantageous route over which the Mineral range may build its spur to the Hancock mine. Probably it will not be decided until the company determines upon the site for its vertical shaft. The Hancock now employs 30 men. A hoisting engine, capable of operating to a depth of 2,000 ft., is being built at Marquette and an air-compressor will be bought from the Sullivan Machinery Company.

At No. 2, the new shaft of the Baltic mine, 400 tons of ore are hoisted daily. The other shafts are not producing quite so much as formerly. The mill is now stamping but 2,000 tons daily. The Wolverine mine has increased its ore shipments to 1,150 tons daily, which is the maximum capacity of its stamp-mill. The yield of refined copper per ton of rock stamp shows no diminution.— Captain Thomas Hooper, who resigned as superintendent of the Victoria mine a short time ago, has been tendered seven different executive positions. He is one of the pioneer mining men of the district.

The Wolverine Copper Mining Co. publishes its annual report and gives some interesting figures. The following is a summary of the year's business :

RECEIPTS.		
9,681,706 lb. copper @ 17.17 cents		\$1,682,142.87
Interest		11,014.14
		\$1,673,187.01
EXPENDITURES.		
Working expenses at mine as per statement hereafter	\$529,668.40	
Smelting, freight, and all other New York and Boston expenses	99,729.83	624,398.23
Leaving a mining profit of		\$1,043,788.78
There has been expended for construction	\$24,814.68	
And for timber lands	11,154.00	35,968.68
Showing a net profit of		\$1,007,820.10
Surplus from previous year was		821,364.54
		\$1,829,184.64
Less dividend October 2, 1905	\$350,000.00	
Less dividend April 2, 1906	480,000.00	830,000.00
Leaving a surplus June 30, 1906, of		\$999,184.64
SUMMARY OF RESULTS.		
Ore hoisted	355,383 tons	
Ore stamped	341,820 tons	
Product of refined copper	9,681,706 pounds	
Yield of rock treated 28.32 lb. per ton, or	1.416 per cent	
Cost per ton of ore hoisted	\$1.49	
Cost per ton of ore stamped	\$1.54	
Cost per pound of refined copper at mine	5 1/2 cents	
Cost of smelting, freight and marketing product, including New York office expenses	1.03 "	
Total cost per pound of refined copper	6.50 cents	
Total cost per pound of refined copper, including construction	6.76 "	

SALT LAKE CITY, Utah, August 18.

The ore and bullion settlements reported last week were \$519,800, and during the same period 146,200 shares of stock were sold on the floor of the Salt Lake Stock & Mining Exchange for \$109,029.

A body of galena has been encountered on the 800-ft. level in the Cyclone mine at Stockton. It has been cross-cut 11 ft. The management of the New Stockton mine has cut its first sulphide shipping ore on the 1,000-ft. level, directly under one of the five shoots opened on the 850 level. The management of the Southport Mining Co. announces that arrangements have been made to develop its property through the Honerine drain adit. W. C. Alexander, the manager, says he will ship ore before the close of the year. Power equipment is to be installed.

Twelve Utah mines posted dividends during July, eight of which represented the Tintic mining district; they were: Beck Tunnel Co., \$25,000; Mammoth, \$20,000; Grand Central, \$15,000; Victoria, \$10,000; Bullion-Beck, \$10,000; Yankee Con., \$15,000; Uncle Sam Con., \$5,000; Carisa, \$5,000. Park City was represented by the Silver King, which paid \$50,000; Mercur, by the Consolidated Mercur, \$25,000; Fish Springs district by the Utah, \$2,000; and Bingham by the Bingham & New Haven, \$22,600.

The Kimberly Nevada Gold Mining Co. has been organized here to operate at Gold Butte, Nevada. O. Wiser of Kimberly, Utah, will be manager. An order for hoisting equipment will soon be placed. — Application has been made for the establishment of a postoffice at Pine Grove, Beaver county, where the Pine Grove Mining Co. has about completed a mill of 40 tons daily capacity. — The Blue Point Copper Mining & Milling Co. has been organized to operate in the Bradshaw district, Beaver county. E. J. Raddatz is president, and F. M. Davis, of Salt Lake, secretary and treasurer.

Improved conditions are reported from the Stateline district, where several properties are shipping, and at no time in the history of the camp has so much prospecting work been in progress. — The ore shipments from Park City this week were 1,986 tons. The Daly-Judge shipped 813 tons; Daly-West, 400 tons; Silver King, 496 tons; Little Bell, 235 tons; Kearns-Keith, 25 tons; other mines, 17 tons. — The West Quincy and Wabash companies, operating at Park City, have levied 10c. assessments. — The management of the Ontario Silver Mining Co. reports good progress in re-opening the drainage adit, closed for the past 18 months. The drift runs parallel with the main adit through hard formation for a long distance, and is believed to have passed the caved portion; a cross-cut is now being run to make connection and release the backed-up water. With the re-opening of the adit, resumption of mining on the lower levels of some of the big mines of the district will be possible. — Development work has been suspended indefinitely at the Diamond-Nimrod property at Park City, which was controlled by Colorado Springs parties.

The Columbus Con. at Atlas is shipping ore which returns about \$40,000 monthly. The ore sells for \$50 per ton and the mill product for \$14.

Ore assaying from \$40 to \$50 per ton is coming from the Wyoming mine of American Fork canyon. — At the Tetro mine, in Tintic district, work is being pushed in the cross-cut from the new shaft to the orebodies, which will probably be erected in another 125 ft. Good results are reported in the development of the Mammoth mine in the Tintic district at depth. Shipments coming from the 2,260 level show 9.5 oz. gold and some silver, bringing the valuation up to \$187 to the ton.

At Bingham a significant strike of copper ore has been made in the Andy adit of the Utah Apex mine. The

vein is 20 ft. wide, four feet of which is shipping ore, principally gray copper and bornite. The Apex Co. is installing an aerial tramway and will soon arrange for the mill equipment. — The annual meeting of the Ohio Copper Co., of Bingham, has been postponed until August 29. At this meeting, aside from the election of a board of directors, the question of incorporating under the laws of another State will be discussed. The management has begun sinking to explore the property at depth and is now in the market for power equipment. — The Century Gold Mining Co., operating in Park Valley mining district, has again started its mill.

The sampling mills of the Salt Lake valley are crowded with business and the two custom plants are preparing to enlarge. No such demand has ever been made upon the sampling concerns before. This is an index of the general prosperity prevailing throughout the mining regions tributary to Salt Lake City.

DENVER, Colorado, August 18.

The Consolidation of the Good Hope, Vulcan, Mammoth, and Chimney mines, situated at Vulcan camp, in the Gunnison gold belt, is an important event, for it will put a stop to litigation that has been brewing for a long time. There is nothing that gives a camp a greater setback than a big lawsuit, so it is an important matter when one of these big parasites is nipped in the bud. Just how much money changed hands in this transaction is not given out, but securities to the value of \$330,000 changed hands, and the Good Hope-Vulcan Consolidated Mining & Reduction Co. was formed.

Oil in paying quantities has been struck over the range, in the new Rangely oilfield in Rio Blanco county. The field is only about 15 miles from the Utah-Colorado line. Six wells have been sunk to a varying depth, from 600 to 2,600 ft. Five of these have struck small flows of oil, but none of them have got a large flow as yet. The best flow is ten barrels per day, which, I understand, may be called oil in paying quantities. The oil has a paraffin base and is of an excellent quality. The Moffat road is to be built within seven miles of the heart of the district. The opinion is expressed by a man who has studied the district that there will be many wells that will get a small and steady flow of oil, but few that will get a large flow, the reason being that the oil-bearing strata are thick, aggregating some 1,500 ft., but they are compact and do not part with their oil rapidly. There is one conglomerate bed that is expected at a depth of 3,000 ft. that may yield a rapid flow. None of the wells have penetrated this stratum as yet.

The deal on the famous old Sunnyside has finally fallen through. Old Judge Terry is very stiff in his price and will grant no concessions whatever to a prospective purchaser. In this case the price was a million dollars, and the property was examined exhaustively by Forbes Rickard of Denver and R. M. Atwater of Helena, Montana. These gentlemen called in other noted men to pass on particular points. Rumor has it that both reports were favorable, but I guess the ore blocked out was pretty close to the danger line in quantity; so, rumor goes on to say, Judge Terry was asked to grant time to develop a little more ore, but he would not do so. The prospective purchasers were Pittsburg people.

The Ahmaden Mines Co., whose property is situated on Fall river about five miles above Idaho Springs, is about to purchase a mill and compressor plant. This enterprising company is composed of Kansas farmers; they took up the old Phillips property and have pushed a tunnel in at the bottom of the hill a distance of about 800 ft.; they intend going on into the hill another 1,000 ft.; they have taken out some of the handsomest native silver specimens that have ever been produced on Fall river. If

they are as lucky as the Kansas farmers that opened up the summit deposit on Gold Hill, Cripple Creek, and then sold out to W. S. Stratton, they will soon all be wealthy.

Speaking of Cripple Creek, Sherwood Aldrich has at last been forced to 'stoop to conquer' on his famous drainage tunnel scheme. Unless something unforeseen happens, the long Window Rock bore will be abandoned and an intermediate adit started very soon.

TORONTO, Canada, August 17.

The manager of the Montreal-Cobalt Co. reports that in the course of operations a gold-bearing vein has been struck yielding at least \$1,000 per ton. Ore containing molybdenum and gold has been found in the Net Lake district, near Temagami, some 20 miles south of Cobalt and within the Huronian range. A number of claims have been taken up and are being developed. The discovery is confirmed by L. O. Armstrong, colonization agent of the Canadian Pacific Railway, who recently returned from a visit to the district.

Interest in the Chibugamoo gold region of Quebec has been revived by the return to Montreal of Peter McKenzie, of the Chibugamoo Gold & Asbestos Co., and H. Massam, of Montreal, after an extended visit to the district, bringing with them numerous samples of rich ore. Mr. McKenzie states that so far there has been but little actual mining done, the work having been confined to prospecting, at which there are some 20 companies at work. Over 700 square miles are under prospector's license. All of these companies have succeeded in finding valuable minerals of some kind. The Chibugamoo Co. has made many open-cuts and has begun the sinking of a shaft. In the open-cuts the ore averaged \$11 per ton in gold and about \$50 in copper. The averages in the shaft were \$24 in gold and \$56 in copper. A 12-ft. vein of nickel-bearing pyrrhotite has also been opened up. There is also much magnetic iron ore in the neighborhood, some deposits being found in the territory of the Chibugamoo Co., and the claims staked by Mr. Massam. Much of it contains as high as 70% iron. A fine quality of chrome iron ore has been found on Lac Doré. The rapids on the Chibugamoo river could be utilized for the furnishing of electric power.

James Ross, president of the Dominion Coal Co., has been on a tour of inspection of the collieries near Sydney, Nova Scotia, and is dissatisfied with the condition of affairs. The output shows a marked decrease, owing to the difficulty of securing an adequate supply of labor. A number of the miners have left for the West. Mr. Ross has made a number of changes in the official staff, abolishing some departments and amalgamating others.

Continued activity prevails in the gold-mining areas of northwestern Ontario. The St. Anthony's Reef mine, owned by the Jack Lake Gold Mining Co., in the Sturgeon Lake district, has yielded \$7,000 in gold as the result of a two weeks' run of the stamp-mills. The shaft of the Baden Powell mine, Eagle Lake district, is down 140 ft., at which level the vein that was only 10 in. wide at the surface has widened to four feet without decreasing in richness. The force at work will be augmented next month. The Detola Development Co., whose property adjoins the Paymaster mine in the Manitou Lake region, promises well. Initial work done under the supervision of the director, John E. Burns, showed that ore from the five veins traversing the property pans freely, visible gold being present in some cases. A shaft has been sunk to allow more thorough testing. A large party of Michigan and Ohio stockholders visited the property recently.

The W. L. McCulloch Co., of Ypsilanti, Michigan, George E. Good, president, is installing an ore pulverizer near Kenora in the Lake of the Woods district. The new plant is claimed to be more economical than the ordinary

stamp-mill.—Horace D. Mayhew, son of President Mayhew, of the Cape Breton Coal, Iron & Railway Co., committed suicide on the 11th inst. at Mira, Nova Scotia, by cutting his throat. Mr. Mayhew resided in England and the deceased represented his extensive interests in Canada.

JOPLIN, Missouri, August 18.

The highest price reported paid for zinc ore last week was \$48 per ton, on an assay basis of \$42 to \$45 for 60% ore, the same as the previous week, although there was a slight advance in the average price. The output was not quite so large owing to heavy rains. Lead ore sold as high as \$78.50 for a few choice bins in the Webb City district. The lead production was never greater than at present, and the price remains stronger than at any time in the history of the district. The shipment for last week was: Zinc ore, 10,906,340 lb., valued at \$240,116; lead ore, 1,460,820 lb., valued at \$55,355. — The Anderson Mining Co., operating on the Granby Mining & Smelting Co.'s land at Chitwood, has encountered a good run of zinc ore in sinking a new shaft. This ore was struck at a shallower depth than the drill had shown when the lease was drilled some time ago, and the shaft will be sunk to the lower run before the upper run is developed. — The Isabella mine, at Alba, owned by the Federated Mines & Milling Co., managed by Allen Hardy, Sr., one of the largest operating companies in this district, made its initial turn-in last week, amounting to 58,390 lb. of zinc ore. — The Chapel Mining Co., operating near Porto Rico, east of Joplin, made its first turn-in last week amounting to 166,080 lb. of zinc ore. This company owns the lease of a large area in that part of the district, having only recently acquired it, and put down several drill-holes, finding ore in nearly all of them. A shaft was sunk and a 300-ton concentrating plant was erected; to this an addition is now being made. — The General Zinc & Lead Co.'s turn-in of lead for last week was 249,770 lb. from its lease near Prosperity.

The largest mining deal made this year was closed Monday, when the Center Creek Mining Co., of Webb City, transferred part of its holdings, the Morgan 40-acres lying north of Carterville, to S. Y. Ramage, of Oil City, Pa., for \$110,000 cash, probably the largest price ever paid in this district for a 40-acre lease on which there were but two shafts and one mill. The Center Creek Co. tested the land by drilling 40 holes, all of which showed ore averaging from 10 to 14 ft. in thickness, and all above the 160-ft. level. The ore is in sheets. After learning what a large area of ore they had, two shafts were sunk, one for hoisting and the other for air; a mill was erected and three months ago they began producing, and every week since they have averaged between 80 and 90 tons of zinc ore. The Center Creek Co. has also given a 60-day option on the fee of the 40-acres to Mr. Ramage, the price being about the same figure as was given for the lease. Another big mill will be erected on the lease by the new company.

The properties of the Ohio, Royal, Egyptian, and Square Deal Mining companies, operating in the Webb City-Carterville district, have been consolidated under one management. The parent company will be known as the Ohio Con. Lead & Zinc Co. This company, or a number of the stockholders, has purchased 53 acres of the Scott land lying south of the Egyptian at Porto Rico. Seven drill-holes put down on this land recently, show a fine run of zinc ore at from 196 to 210 ft. — The Criterion Mining Co., operating near Porto Rico, is planning the erection of a 400-ton concentrating plant to be operated by electricity. Except for the Underwriters 1,000-ton mill, at Webb City, this will be the largest electrically operated mill in the district.

LONDON, August 8.

When those now departed heroes of finance, Cecil Rhodes and Alfred Beit, with others of less fame, worked out their schemes for the control of the diamond mines at Kimberley, they recked little of the British income-tax collector. De Beers Consolidated Mines, as a company registered in South Africa, was not in those days considered to come within the Income Tax Act as residing in the United Kingdom. But if the income-tax wheels grind slowly they have been grinding pretty surely of late years and at last De Beers has been added to the list of cases won by the Government on the ground that a company resides for purposes of income tax where its real business is carried on. Although the head office is formally at Kimberley and the general meetings have always been held there, it is established finally in the House of Lords, on an appeal from an order of the Court of Appeal, that the majority of the directors and life governors live in England, that the directors' meetings in London are the meetings where the real control is always exercised in practically all the important business of the company except the mining operations, and consequently the company's centre of trading is in England under the protection of English law.

The report of Tanganyika Concessions Ltd. shows that some further progress has been made in carrying out the ambitious programme for which the company was formed in 1899 with a nominal capital of something over half a million sterling in shares of £1 each. The interests involved are rightly declared as vast. They include a concession on Lake Tanganyika at the projected terminus of the Cape to Cairo railway, copper mining claims in northwestern Rhodesia, the Benguela mineral rights over a large area in Congo Free State, and the construction of the Lobito Bay (Benguela) railway. The principal mine now worked for gold is the Ruwe, which has given a total production to May last of 9,175 oz.—interrupted for part of last year by a shortness of the food supply. Development work upon the lode has been carried on at water-level for over 800 ft., and boring by diamond-drill is proceeding in order to prove this bed in depth. By the middle of next year the Rhodesia railways are expected to be within 300 miles of Kansanshi by a motor-road which is reported as practicable and good for all except the wettest months of the year. The engineer states that so long as the lodes maintain their present strength the Kansanshi mine will yield upward of 100,000 tons of ore for each 100 ft. in depth, and so far it runs about 20% copper per ton. The present intention is to develop the mine to 300 ft. deep, and every effort is being made to augment the machinery.

In the way of transport, something like a record has been achieved in connection with the Ruwe mine. There were 1,200 miles to traverse, and the wagons, with 320 light rails and four trucks, which left Benguela on May 2, arrived at the mine on December 24. Such difficulties of transport are likely to hamper the company's operations for some time to come, but this fact does not prevent the shares from being dealt in at a large premium. Following South African traditions, although without any prospect of dividends in the near future, the stock was engineered to as high a figure as £25, but unable to withstand the general slump, the price fell to under £4, on which an improvement has taken place since the issue of the report. Another big enterprise which has suffered severely from the South African situation is the Central Mining & Investment Corporation, familiarly known as the 'Six-Million Trust,' a reconstitution in May, 1905, of African Ventures Syndicate, itself formed some two years earlier. One of the objects of the Trust operated by Wernher, Beit & Co., as managers, was to support the Kaffir market, which in spite of their powerful

assistance continued on the down grade to such an extent that the Trust has had to set aside the large sum of £1,449,000 for depreciation on the basis of market prices at the end of June. Needless to say the Trust stock itself has meantime been subject to a heavy fall below par.

In describing the policy of the Company at the recent general meeting, Sir Julius Wernher said that "they proceeded slowly and cautiously to buy certain interests partly developed, and partly in course of development. They were buying in a falling market, but the collapse which followed was quite beyond human foresight. The war had disorganized the industry to a greater extent than was realized at first, when people returned, after a long exile, full of hope. The greatest difficulty was the impossibility of getting sufficient unskilled labor." Referring to the fact that most of the mines now gave a lower return, Sir Julius thought their main hope lay in a substantial lowering of working costs and prolongation of 'life.' As a proof that it hardly looks as if the Government intends to abolish Chinese labor, the story goes that the Chinese regiment (among others) has been disbanded, but, at the same time, all the officers of the regiment—and also all officers who have qualified as interpreters of the Chinese language—have been apprised by circular of the fact that the present Government proposes to appoint several inspectors of Chinese coolies in South Africa at £800 per annum, and will be glad if all officers conversant with the Chinese language will apply for appointments.

The better news to hand during the past week as to developments at depth on the Great Fingall (W. A.) would seem to point to the realization before long of the improvement at the No. 13 level anticipated in the manager's report, to which attention was drawn in my correspondence of April 25. The winze from the No. 12 level at 580 ft. north has been put down 222 ft., the average value for the last 36 ft. being 32s. 6d. per ton for a width of 5½ ft., while the cross-cut to foot-wall 200 ft. below No. 12 level north shows the reef to be 11 ft. wide and to assay 34s. per ton. On the No. 11 level, too, the raise at 215 ft. south has been extended 54 ft., the assays averaging 33s. 3d. for a width of five feet.

Progress reports arriving from Mexico continue to be favorable to mining speculators in that quarter. With regard to El Oro, Mr. Raymond, the general manager, cables that in a drift south from the shaft on the 1,000-ft. level of the San Rafael vein, he has encountered an ore-body five feet wide, composed of quartz and slate mixed with pyrite having an average assay-value of 20 dwt. per ton. He states the vein is not well defined, but is showing great improvement and that indications are favorable. Dolores cabled returns for June—gross value \$48,500 from 1,150 tons treated with profit of \$27,500—while marking progress, is somewhat disappointing to stockholders as showing that the mill is not yet running to its full capacity although crushing was started more than a year ago. It is understood, however, that the returns are likely to be considerably increased in the near future and it is said that the developments at the bottom level continue to point to a greatly enhanced value in the ore reserves.

Interest in metalliferous mining at home has not been quite so keen, owing, perhaps, to the holiday season, but a 'gold rush' is reported in Ireland. It is rumored that much interest has been aroused in Roscommon by a discovery made in a quarry at Boho, near Castlerea, where some workmen, during quarrying operations, found between two layers of rock a lump of virgin gold about the size of a goose egg. The fact that the nugget is composed of the precious metal has been confirmed by a Dublin analyst. Copper mining is still attracting attention in the country; the Irish Copper Mines, Ltd., was

registered last week with a nominal capital of £60,000. Amongst the subscribers is the name of Lord Armstrong for 10,000 shares.

The visit paid to this country by the American Institute of Mining Engineers is regarded as an event of the highest industrial and scientific interest. The occasion has been made use of to compare the pigmy proportions of our iron and steel trade with those of its transatlantic competitor. It is, however, consoling to note that we "export far more iron and steel than any other country; twice as much as the United States, and nearly 50% more than Germany," and that while "with the United States large exports of iron and steel are generally a sign of adversity; with the United Kingdom they are a sign of prosperity."

BUTTE, Montana, August 18.

The properties secured from Heinze by the Red Metal Co. are being put in shape to make a big showing in the near future. Nearly all their work at present is in the line of development and exploration, the biggest strike, so far, having been that in the Minnie Healey on the 1,100-ft. level. In the meantime the sinking of the Corra shaft has been resumed under contract, and will be sunk several hundred feet. The stoppage of the work was partly due to trouble with contractors, sinking and raising being chiefly carried on by contract in this district.—A. C. Carson, superintendent of the Red Metal & North Butte Co., says that the system of intermediate drifts, which was extensively used in all the Heinze mines, is being discontinued and all chutes are being built to the sill-floors, instead of ending half-way down the stopes as formerly. The intermediate system afforded an expeditious way of getting out ore, but is not considered satisfactory in the long run. The Speculator mine is now hoisting ore in skips, but the loading-chutes on the three levels are not yet finished and the amount of ore hoisted is therefore limited. The chutes will be ready for use by the end of the month when the output of the mine will be nearly doubled by the improved facilities for hoisting. At present the mine is raising about 1,000 tons per day. The Nordberg compressor, built for 35,000 cu. ft. of air per min., was recently put in operation. The Corra is hoisting 200 tons daily; the Rarus from 600 to 700 tons; and the Minnie Healey from 500 to 600 tons per day.

The mines on the hill are all sinking their shafts since the strike on the 2,400-ft. level of the Anaconda last winter. The High Ore shaft has been sunk to the 2,400 to handle the water from the Anaconda and neighboring mines, which had become deeper than the High Ore. The Never Sweat shaft, through which considerable Anaconda ore is hoisted, is now the deepest in camp, having reached the 2,500-ft. level. The Never Sweat hoisting engine was recently re-adjusted on its foundation, owing to movement of the ground, and will probably be moved farther back from the foot-wall during the summer. Last month the mine was closed for two weeks owing to the settling of the engine. When the work of moving it to a permanent position is commenced, it will be necessary to close down the mine for perhaps two months. No development is going on in the mine at present, and the filling used is waste from the Bell and Diamond mines, which is moved at a cost of 30c. per ton. One shift is employed entirely in lowering this waste into the mine and tramping it to the stopes. There are 200 men working in the Never Sweat at present. It is thought that the importance of this shaft will be lessened when the company has the Belmont, or some shaft on the lower ground to the south, in condition to hoist Anaconda ore mined in the south vein, which is several thousand feet from the shafts of the Anaconda and Never Sweat.

The Pennsylvania mine of the Boston & Montana Co.

has the foundations nearly ready for their new hoist. The round cables are now replacing the flat ropes in this, as in all the deep mines of the camp, flat ropes having been almost exclusively used here for many years. The flat cables necessitate the keeping of a rope-gang to repair them from time to time, and it is considered cheaper to buy round ones, use them for a year or two, and replace them with new. The Pennsylvania is hoisting about 900 tons per day.

The Butte & Boston Co. is opening up the old Berkeley shaft on the Never Despair claim, and has already taken out some good ore. The shaft is 800 ft. deep, having been abandoned several years ago. The mine will be developed, and it is thought will yield at least 300 tons per day. Mining was resumed this week in the old stopes.—The Davis-Daly mines are getting into shape for mining in the near future. Three new compressors and two hoists have been installed on the Mt. Moriah, Colorado, and Plymouth. The hoists have capacity to sink the shafts to the 1,000 level.—The Butte & Superior Copper Co., which was recently organized to work some of the northern claims bought from W. A. Clark, is purchasing several others in the same neighborhood. The Deadwood claim is under bond, the deal having been closed this week. Negotiations are still pending for the Damarat, Laura, and Enterprise. The purchase price of the Niagara and Raymond is about \$360,000 for each, while that of the Jersey Blue and Four Johns together is \$250,000.

B. F. Shearer and H. Bush, of Pittsburg, have secured control of the Bear Gulch properties near Yellowstone Park, which are said to contain rich veins of tungsten. The mines there have produced copper and silver for years, and it was only lately that tungsten was recognized. Both scheelite and wolframite are found. It is said that a shipment of 60 tons from the dump sold for \$20,000 in Denver some time ago. The property is controlled by the Montana Tungsten Co. of Pittsburg and Gardiner, Mont. Within 90 days, according to Mr. Bush, mining will be in progress at the new camp.

It is stated on the authority of one of the chief engineers of the Amalgamated Copper Co. here, that in the report soon to be made by John D. Ryan to the directors of the Amalgamated Co. in New York, regarding the settlement of the disputed claims in the mines secured by the Red Metal Co. from Heinze, it has been determined that each company shall keep within the vertical planes of the lines of its claims; that is, neither shall take any extra-lateral rights. The adoption of this rule is made possible by the fact that the two companies own practically all the mineral lands adjoining the disputed portions. The mines affected will be the Minnie Healey and Rarus, of the Red Metal Co., and the Michael Davitt, being Butte and Boston property, and the other two belonging to the Boston & Montana Co. The Rarus is cut by two noted faults, and it was Heinze's contention that the veins apparently apexing in the Michael Davitt and Pennsylvania, were in part veins belonging to the Rarus directly north of those claims. He accordingly stoped much of his ore in ground lying under the surface of those two claims. In the Minnie Healey he contended that the veins dipped north under the West Colusa, and he was allowed to stope in both places by the courts. Although this settlement of the affair will take much of the ground formerly worked by Heinze, there will be some veins in both Red Metal mines which would otherwise belong to the adjoining claims, that they will now be at liberty to work.

A similar arrangement to avoid possible litigation between mining companies owning adjoining mines, was mutually adopted some time since in some of the large copper mining camps of south-eastern Arizona.

Mining Summary.

ALASKA.

The Bartells Tin Mining Co., of Tin City, Alaska, states that the first load of tin concentrate was shipped from the property on August 1, consigned to Seattle, where it will be sold to smelters. The Bartells Co. has spent a great deal of money in the development of its property. It is expected to send out from these mines several more cargoes this season.

A rich placer strike on the western side of Kenai peninsula, back 15 miles in the interior from Nenehchuck, has started a stampede to the diggings, which are on Deep creek, and Bat creek, a tributary. It is reported that 50c. per pan is common. Miners from various places along the Inlet and Turnagain Arm have flocked in to the number of 100 or more. The Inlet steamer Neptune was beached at Nenehchuck by the captain and crew while they went to Deep creek to stake ground. The original discovery was made by a Russian, John Kashevnikey, of Nenehchuck, who told Chris Hansen, an inlet miner, and the two went to the place together. Hansen and Kashevnikey staked claims and went to work. In a short time Hansen appeared at Seldovia with \$200 in dust which he exchanged for an outfit and returned. In the meantime news of the discovery had reached the Inlet camps and the stampede was on. It is a region of low, rolling hills. Nenehchuck is a Russian settlement of 30 families a short distance up the Inlet from Anchor Point, where beach diggings have been worked for several years.

ARIZONA.

With the production of the first six months of the year on which to base calculations, the copper output of Arizona for this year promises to reach 300,000,000 lb. The monthly output of the various mines and districts is as follows: Bisbee, 12,500,000 lb.; United Verde, 8,000,000 lb.; Arizona Copper Co., 3,000,000 lb.; Globe district, exclusive of Mexican ores, 2,500,000 lb.; Detroit Copper Co., 1,750,000 lb.; Shannon, 1,250,000 lb.; Silver Bell, 500,000 lb.; Arizona Smelting Co., 400,000 lb. The June output of the Old Dominion Co. at Globe, was over 3,000,000 lb. The output of the Copper Queen for June was 8,000,000 lb. The new 200-ton smelter, at Helvetia, which will be blown in soon, will add materially to the total output for the territory.

COCHISE COUNTY.

A strike was made recently on John A. Duncan's Santa Fe claim near Paradise, in an open-cut, 20 ft. wide and 30 ft. long. Nearly one-third of the face of the cut is in pay ore mostly azurite and malachite.

COCONINO COUNTY.

W. W. Bass reports a strike near Bass' station on the Canyon railroad. In the past thousands of tons of ore have been shipped to the smelters at Pueblo and El Paso, but the establishment of the custom smelter at Humboldt will make it possible to ship ore to that point that heretofore was too low-grade to afford a profit by shipping.

GRAHAM COUNTY.

(Special Correspondence).—The headquarters of the Hot Springs Oil Co. has been moved to Safford, and last week at a meeting of the directors, it was decided to move the oil-drilling outfit from Hot Springs to Safford. Mr. Zierath and Mr. Morris have been in Safford three weeks securing land through lease and by location.—West, Clark and Rising last week closed a deal with parties at Globe for their property 14 claims in the Stanley Butte district, for \$30,000, to be paid in 50 days. This is the property on which a strike was made three months ago.—The Stanley Butte Copper Co. now has 25 men at work bettering the grade of the road from San Carlos to their mines, made necessary by the heavy hauling they will have to do in transporting the machinery. This company also has a force at work on a double-compartment shaft which they are sinking, and at which they will place a hoist.—The Morgan shaft of the Twin Buttes Mining Co. is down 270 ft. Three eight-hour shifts are worked with 30 men on each shift. The main shaft, 7 by 16 ft., is all in ore, and the width of the vein will not be known until it has been cross-cut.—The Arizona Copper

Co. will replace the 10 h.p. electric hoist at the Clay mine by one of 50 h.p.—Mining interest among all property owners of this district has been given an impetus by the fact that the Southern Pacific Railroad Co. has given a contract to the Langtry-Sharpe Construction Co. for the completion of 300 miles of road in three years. The proposed line will have one terminal at Durango, Colorado, and the other at some point in Arizona on the Southern Pacific. The road will run through San Juan county, New Mexico, a coal district, cross the Santa Fe railroad at Gallup, in another coal district, pass down the valley of San Francisco river and through Clifton and Morenci. This road will open up an important fuel region and facilitate obtaining coal and coke for the smelters in this district.

Morenci, August 17.

YAVAPAI COUNTY.

The Golden Idol Mining Co., with properties on Cherry creek, northeast of Prescott, expects to have a mill in operation on the group of four claims this fall.

CALIFORNIA.

BUTTE COUNTY.

(Special Correspondence).—At Marysville it is reported that W. T. Ellis, Jr., is endeavoring to secure options on a number of agricultural tracts east of that city; it is thought, to combine the property under a single ownership, and then to explore the territory for mineral. The land is situated in the recognized copper belt passing through this part of the State.

Marysville, August 18.

CALAVERAS COUNTY.

Twenty men are employed at the Nassau copper mine on the Pool ranch. At the 100-ft. level a drift has been run 200 ft. and stopes opened. At the 200 level the vein has been uncovered for 50 ft., where it averages 15 ft. in width.

MODOC COUNTY.

(Special Correspondence).—Four men are working on the Kafader group driving a cross-cut to reach the vein on a porphyry-limestone contact. The shoot, where opened on the surface, shows specimen ore on the contact, and the porphyry prospects for a width of 10 ft. A company has been incorporated to develop the Maupin vein, which has been prospected to a depth of 30 ft., the ore assaying 8 oz. silver and 1 oz. gold per ton. Recent finds of high-grade ore have been made. The Sunset vein is being developed by an adit, the quartz, carrying silver and gold.—About 25 tons of free-milling ore have been taken out of the Sugar Pine claim, at the surface. The ore was only discovered during the past month. The vein is vertical between shaly andesite and massive porphyry, and is 2 ft. wide; it mills \$35 per ton, and assays \$40 to \$50. Some specimen ore has been found at the intersection of a rhyolite dike with the vein.

—The Wade-Plummer is to be developed by a new shaft. Dr. Patterson has acquired four-tenths of the property, and the remaining interest is under bond to Stribling & Hornback. The best ore assays \$40, but the surface pans well along the contact.—A strike of rich ore has been made of ribboned quartz and lime, on a contact supposed to be phonolite. It is situated at the Mineral Spring camp. A busy lot of prospectors are at work in the vicinity. A stampede was created at Fort Bidwell, and Lakeview, Or., August 8, by John Loftus sending in rich samples for test, the ore, quartz stained black by iron, assaying 10 oz. gold and 1 oz. silver. About 50 teams have already passed through Adell, on the road to the strike, which was made in Windy Hollow, eight miles northwest of Plush, Oregon. This district is similar to that about the Sage Hen mine, which has been prospected for 12 years. The ore assayed well but would not pan, and not until within the last month has free gold of consequence been found. The ore is reported to be 100 ft. wide. This outcrop is considered a continuation of the Warner range. The latest news from arrivals is that large dikes from this and the adjoining district show heavy panmings of gold. The ore is hematite in quartz and lime.

Fort Bidwell, August 18.

NEVADA COUNTY.

Prospects at the Jenny Lind gravel mine are bright. It is reported that since the mill has been changed to work

gravel, during the 14 days it has been in operation, 558 cars have been put through as a trial run, with better returns than had been expected. The Jenny Lind is believed by many to be the extension of the Alta lead, which produced very rich gravel.—The drain-adit at the Austin mine in Willow valley, near Nevada City, is nearly completed. It will tap the shaft at a depth of 250 ft. on the pitch of the vein, while the shaft is only down about 190 ft., so it will have to be sunk 60 ft. before the adit is reached. As soon as the adit is finished, sinking will be resumed.—A rich strike is reported on the 1,100-ft. level of the Empire mine, near Grass Valley. It is the oldest quartz mine in the district, having been worked practically without cessation since 1850.

SIERRA COUNTY.

(Special Correspondence).—It is reported that rich gravel has been struck in the Bellevue mine near Gibsonville.—At the Happy Hollow mine 12 men are doing well in a drift mine. Charles D. Akers is superintendent.—The Herkimer mine has been constructing a ditch 4,000 ft. long to run the air-blast. As soon as completed three shifts will be put at work in the mine.—Peckwiths & Spaulding struck gravel worth \$38 per ton in the West Point mine, near Downieville, last week.—The Telegraph mine is getting specimen rock in the bottom of the shaft, which is 50 ft. below the adit level.—C. J. York is building a five-stamp mill at his foundry at Downieville for his Mexican claim near town.—John Henderson is constructing a five-stamp mill for J. L. Buckingham on the Elsie mine in Jim Crow canyon.—The King Con. Mining Co., operating near Loganville, has purchased from J. W. Finney the 20-stamp mill at the Sierra mine and will remove it to its mine at Loganville, that has been developed recently. It is opened to a depth of 500 ft. by an adit. The vein is from four to five feet wide. A recent mill run proved satisfactory. John Hayes is superintendent.—The Marguerite Co. is running its 20-stamp mill and expects soon to have the water out of the shaft and resume sinking.—The Keystone mill is again running after a hang-up due to the breaking of a shaft.—The Sovereign has a cross-cut through a 20-ft. vein in two places that prospects well in free gold besides sulphides.—The Empire Co.'s mill in Gold valley is idle during repairs and the building of a cyanide plant. Men are doing development work in the mine.—The Los Angeles Co., that has a bond on the Columbo, has men repairing the adits and getting out timbers.—H. L. Johnson has made another rich strike at Alleghany, in the El Dorado claim, formerly owned by Fessler & Lewis. The Oriental Co., under the management of H. L. Johnson, has struck pay-ore in the lower adit.

Downieville, August 18.

TUOLUMNE COUNTY.

(Special Correspondence).—The Longfellow mine, at Big Oak Flat, is now being operated with power furnished by the Tuolumne Electric Co. The Mack mine, adjoining it, will be started up this week with electric power. Matt Jacobs, who will have charge of operations at the latter mine, arrived a few days ago. — Machinery is being purchased for the mine of the Springfield Tunnel & Development Co., near Columbia. At a meeting of the directors last week, Nathaniel Clark was elected president. — The mill on the Hunter mine, near the Buchanan, south of Tuolumne, has started on ore from the Paymaster, the property of the Standard Mining Co. — J. Ross Clarke, accompanied by R. A. McWilliams and his secretary, has been examining the Patterson mine near Tuttletown. — The Yellow Jacket, Good Luck and Ophir mining claims, better known as the Driesam group at Arastraville, will be sold at commissioner's sale in Sonora on September 12 to satisfy a judgment against the Driesam Gold Mining & Milling Co. obtained by Jas. E. Conde, et al. The plaintiff in the case held a mortgage of approximately \$10,000 on the property.

Tuolumne, August 20.

A rich strike is reported made at the mine on the ranch of Ida Kline, near Stent, by J. N. Lyon, J. McFarland, and Lew Baum, who have a bond on the property and who have been prospecting it for some time. Assays run into thousands of dollars per ton, and in some parts of the vein the

gold is in coarse pieces and layers. The rock also contains sulphides which assay from \$70 to \$500 per ton. The discovery was made during the latter part of last week in a swampy spot that had not been disturbed by the pick of the prospector. As a result, the Calico mine, at which operations were recently stopped, has been started up again and will be worked with a full force. The strike is certain to create greater activity in that part of the Mother Lode.

Tuolumne, August 21.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The new strike in the Doric tunnel of the X-Ray Co. is the sensation of the week. A raise was started from the east drift in the Cram lode, cut by the tunnel at 2,400 ft. in from the portal and about 2,000 ft. vertically below surface. At 20 ft. up the ore opened out to a 4-ft. vein carrying over a foot of solid galena which runs 50% lead, the rest of the orebody being iron and copper pyrite with thin veins of polybasite running through it. Assays as high as 4 oz. gold and 600 oz. silver per ton, with 7% copper have been obtained from this ore. At 400 ft. farther ahead in the adit the Sequel lode, which has been followed for 200 ft. east-west, shows an 8-in. vein of ore nearly the entire length of the drift, which carries 1.5 oz. gold, and 400 oz. silver per ton and 17% copper. This mine is situated almost within the town limits.—The Main Gulch Co., operating the Smuggler mine which recently struck a body of high-grade silver-lead ore while sinking in the main shaft, has made arrangements with the Whiting Co., owners of the Terrible mill, to treat its ore. A cable tramway, 1,500 ft. in length, is being erected from the shaft-house to the mill in the valley below. The company has a 3-ft. vein of lead-zinc ore in the 90-ft. level from the shaft. It was to exploit this that the old Smuggler mine was re-opened three months ago.—The Two Sisters Mining & Power Co. has the building for its electric power-plant well under way. When the water in Clara creek is lower next month, the dam which was commenced last winter, will be completed. The plant is designed to give 500 to 600 h.p. the year round. Electric light and power-lines will be strung to the company's mine at Silver creek, where a large concentrating mill is in course of construction. The old dumps of the mine contain 75,000 tons of milling ore, stated to be worth \$7 per ton. New orebodies are now being opened in the levels east and west from the Headlight shaft which is down 275 ft. In the 160-ft. level there is a continuous vein 18 in. in width for 200 ft. carrying \$20 in zinc and lead and 25 oz. silver per ton.—The schedule on lead issued by the American Smelting & Refining Co. gives a raise of 14.5c. per unit. The Chamberlain Sampling works here are now paying 11c. per unit more for lead than heretofore, which brings their price for lead up to that which the Santiago mill and independent sampler have been paying.—Much attention is now being given that portion of Leavenworth mountain north of the Colorado Central mine. The Key West Co., operating the McKinney mine; J. Schuler on the Herkimer; Patterson & Co., on the Fort Dodge; Kendall & Sprouse on the Argentine and Creole, and the Georgetown Leasing Co. on the Brannigan, all have good showings of ore, and are getting shipments ready.

The Capital tunnel, now in 3,800 ft., will, it is thought, this week cut the Etna lode, an extension of the Colorado Central vein, at 1,600 ft. from surface. The Butte silver lode, recently intersected by the adit, shows an 18-in. vein of lead and iron sulphide.—The annual report of the Transcontinental Transportation & Mining Co., shows it has \$207,855 cash on hand, having expended up to date \$46,108. This money was all subscribed in London. The company is driving a 12 by 16 ft. tunnel through the top of the range underneath Argentine Pass, the total length of which will be 7,000 ft. It is now in 1,400 ft. from this side and work has been started on the western slope. Two 80-h.p. boilers and a 150-h.p. air-compressor have been ordered, which will supply power for machine-drills on the western side. This tunnel will connect the Atlantic and Pacific slopes by the shortest possible route, and its conversion into a railroad tunnel is a foregone conclusion.

Georgetown, August 18.

FREMONT COUNTY.

A rich strike of silver ore is reported from the vicinity of Florence, two miles west of Spaulding. Many claims have been located by prospectors who rushed to the new field as soon as the strike became known.

LAKE COUNTY.

The first large shipment of ore ever made from the territory west of the Iron Hill fault, and south of California gulch, is credited to the New Emmet, formerly known as the Crescentia lease, operated under the management of A. F. Wuensch, one of the lessees. The orebody is in limestone and is 12 to 15 ft. wide of clean ore. The crevice is nearly vertical. The height of the shoot has not been determined beyond about 15 ft., though it is presumed it will continue up through the limestone to the porphyry contact, the distance to which is not known. The trend of the channel is northeast-southwest, and has been opened 100 ft. The mineral next to the limestone walls is largely ferromanganese, assaying 10 to 20 oz. silver per ton, with a little lead. The central portion of the shoot is a fine looking sand carbonate with a little galena, and assaying 5 oz. silver and upward. So far about 750 tons have been shipped to the smelter.

MINERAL COUNTY.

Creede district has shipped 40,320 tons of ore and concentrate to smelters during the first seven months of the current year. The concentrate represents reduction of four to five tons of ore into one. The Creede United Mines Co. is operating on the eight-hour schedule and has changed its pay-day to the first of each month. Henry Brandt is putting an air-pipe line into the cross-cut adit on the property of the Rio Grande Mining Co. at Spar to supply air to the miners working in the face.

TELLER COUNTY.

An unusual contention has developed in the District Court of this county in an application for an injunction against the Indicator Gold Mining Co. and lessees, restraining them from proceeding further in sinking a shaft on the Indicator fraction, on Beacon hill. The plaintiff in the case is M. B. Burke, owner of the Henry Adney, which is situated 200 ft. down the hill from the Indicator fraction. Burke sets forth, in his application for an injunction, that defendants are now engaged in sinking a shaft through a solid granite dike about 40 ft. in thickness, and that this dike backs up a water course and that if it is pierced the workings of the Henry Adney at a depth of 600 ft. will be inundated, and the lives of miners in the property who are working directly beneath the dike will be endangered by the flow.

IDAHO.

BLAINE COUNTY.

The Cracker Jack mine, in the Buffalo Hump district, is being investigated with a view to furnishing the mines with power. Operations in the Buffalo Hump district have been handicapped for the want of cheap power, and the Cracker Jack expects to build a dam and use its 100 ft. of additional head. As the result of operating two stamps during July the company netted \$1,100, and in addition to this \$170 was netted from three tons of concentrate treated in the chlorination plant of the Jumbo company.

BOISE COUNTY.

John Treweek, manager of the Sunnyside mines in Thunder mountain, will construct a cyanide plant, the initial capacity to be 100 tons daily. The enlargement of the plant will follow as rapidly as facilities will permit, the power ultimately to be electricity. A plant will be installed next summer.

IDAHO COUNTY.

(Special Correspondence).—What is said to be the richest gold strike made in Idaho in many years is reported in an abandoned tunnel near Florence, east of Spokane, where gold is found in decomposed ore, assays of 10-lb. samples running from \$3,500 to \$5,800 per ton. The ore is free-milling. According to Government reports, Florence was at one time one of the richest gold camps in the West. In its boom days there were 10,000 men in the district. George Hearst

and Joaquin Miller were among those in the camp in those early days. A stampede to the place is in progress.

Spokane, Wash., August 18.

Charles Ellison, of Elk City, has made a good silver-lead strike on his property in the vicinity of Profile gap, in the Big Creek district. The ore was found 350 ft east of the Crown King adit. The ore resembles that of the Cœur d'Alene district. The camp is well watered and has plenty of timber available. About 10 or 12 miles of the wagon road remain uncompleted from the south fork of the Salmon to Government creek; the miners of Profile camp have turned out in a body to finish it and are working near the mouth of Elk creek. When this road is completed machinery will be installed in the Pan-Idaho property.

SHOSHONE COUNTY.

(Special Correspondence).—Work will be resumed in a few days on the Blue Grouse property in the Cœur d'Alene district and will be continued throughout the fall and winter.—The Tamarack & Chesapeake mine in the Tiger Peak district will increase the working force and prepare to ship ore.—F. Augustus Heinze is said to be negotiating for the purchase of the Rex mine in the Cœur d'Alene district. He and his associates own the Stewart mine, and it is said that with the acquisition of the Rex a smelter will be established.—Thomas Thwaite, of Spokane, has taken a bond on the Highland Chief claims near Wardner for \$178,000, near the Stewart mine.—W. D. Greenough, manager of the Snowstorm mine at Mullan, when in Spokane today, said that a dividend of \$90,000 will be paid September 10. The present company took charge of the property July 10.—The Snowslide Mining & Milling Co. at Mullan has been incorporated with a capital of \$1,000,000. George Snow is president.

Wardner, August 18.

The Comet Mining & Milling Co. has voted to levy a four-mill assessment to raise funds to develop the group of five claims owned by the company on Pine creek, near Wardner. Some galena has been found in the mine.

MONTANA.

BEAVERHEAD COUNTY.

The Silver Fissure Mining Co. is working its mines, at Polaris. A traction engine was recently put on the road. The smelter is expected to be in working order early in the fall.—H. R. Melton says the Iron Mountain mine, at Argenta, has the adit in 700 ft., and 50 in. of water is running out of it now. Since striking water, one spring above has quit flowing and all the old prospect shafts in the vicinity are being drained of water. Jas. Phillips has appropriated the water flowing from the mine into the Rattlesnake creek. A cross-cut will be made to the Iron Mountain shaft which will supply air, when the compressor now in use may be dispensed with for a time. So far no orebodies have been encountered in the adit.—S. Roberts, foreman of the Monument Mining Co., in the Bloody Dick mining district, says that night and day shifts are worked in an adit now in 270 ft. At 500 ft. it is expected to reach a vein of gold and copper ore.

NEVADA.

NYE COUNTY.

(Special Correspondence).—There is already in the bank a sufficient sum for the erection of a large stamp-mill in Manhattan district. It will at first have 25 stamps, to be increased as the demand warrants. Engineers who are investigating the water question have instructions to go 50 miles from Manhattan, if necessary, to get a suitable supply. The mill is expected to be ready to handle custom ore by November. Several carloads of ore have been shipped to Salt Lake for experimental test. Milling ore is being piled awaiting the erection of this mill. Contracts for other mills have been let, and extensive mining will be done in Manhattan district this fall and winter.—New strikes continue to be reported almost daily. — In the adit on the Georgey group of the Manhattan Nevada Gold Mines Co. at Central, a 12-ft. vein was encountered when in 75 ft., and recently a drift started on this vein, to find the pay-shoot, struck \$35 ore when in 10 ft. This ore resembles that from the Manhattan Con. The adit is in 155 ft., and another vein has

been cut. Samples taken from the face of the adit assay \$15 per ton gold. — A small vein of high-grade quartz has been uncovered in the Muleskinner claim of the Manhattan Mother Lode Mining Co. by prospectors who were tracing a vein across that claim into their ground adjoining. The stringer was covered under a foot of wash, and had not been noticed by the management. Men will be put at work on this new find. — Good ore has been encountered in the adit of the Consolidated Manhattan Mining Co. at East Manhattan, where a six-foot vein assays \$42 per ton gold. A drift will be started on this vein. This is the twenty-third vein that has been cut in the Consolidated Manhattan adit, each of which contains gold, but the last vein is best, so far. — The Manhattan Mammoth, adjoining the Consolidated Manhattan on the east, has also struck good ore in its adit, as has also the Manhattan Jumbo, in a shaft which is being sunk close to the town. — Still further east, and a little south of East Manhattan, the Hindocraft property reported a strike last week, and development has opened up high-grade ore. — The Manhattan Giant, adjoining the Manhattan Nevada Gold Mines Co. on the north, has an eight-foot vein of milling ore in its incline shaft.

Manhattan, August 18.

LINCOLN COUNTY.

(Special Correspondence). — The Pacific Coast Mines Bureau, of Los Angeles, recently purchased the Duplex Extension mine adjoining the Brockman mines, and J. D. Reaves, their representative, has outlined a plan of development. — Henry E. Carter, manager of the Searchlight Mining & Milling Co., states that his company will install a steam-plant. Two 70 h.p. boilers have been purchased to run the pumps. The water will be used as fast as pumped, in the mill and cyanide tanks. Mr. Carter is putting in a cyanide plant. — H. B. Adsit has purchased the Dora group of three claims from Charles Vanina, the group adjoining the property of the Colorado Mining & Milling Co., of which Mr. Adsit is president and manager. The double-compartment shaft is being carried to the 200-ft. level. Mr. Adsit also bought a half interest in the Red Bird group from W. J. Kennedy. These claims adjoin the Colorado Mining & Milling Co. on the south. — The latest Denver concern in the field is the Samuel R. House Co. They have incorporated as the Searchlight Quintette Gold Mining Co., to develop five claims on Doherty mountain. The property is situated near the Boston group, the Southern Nevada and Santa Fe, and the Duplex properties. Present development comprises a 50-ft. shaft and a 50-ft. adit. On the Azusa, west of the Quintette, and apparently on the same vein, ore has been found which assays well in copper; copper has also been found in the Waterspout shaft to the south, and ore from a 10-ft. shaft on the Quintette assays \$20 per ton copper.

The Pittsburgh-Searchlight Co. was organized during the past week to develop claims a mile east of town. — The main shaft of the Leafstalk Gold & Copper Co. is down 70 ft. on a three-foot vein of gold-bearing ore, samples assaying \$127 per ton. Copper and lead are also found. — The Adsit shaft on the Gray Ghost is down 50 ft. A hoist is being erected and two shifts employed. — Vontrigger, in the Signal district, in San Bernardino county, Cal. is the scene of another strike. The California Gold & Copper Co. owns nine claims there. At the 200-ft. level a cross-cut passed through 18 ft. of sulphide ore carrying 20% copper, and the hanging wall has not been reached. Twenty-five men are employed. The mine is equipped with hoist and machine-drills. A smelter of 100 tons capacity is planned. — The Searchlight Midas Co., a Denver corporation, has completed 50 ft. of a 200-ft. shaft. The property consists of three claims formerly known as the Blue Bird group, situated one mile east of town, near the Boston group. — At El Dorado Canyon, the bonding of the Judge Parker group this week by H. J. Humphreys to Denver parties, represented by R. H. B. Warburton, is said to be a \$50,000 transaction. The time limit is one year, during which a stated amount of development must be accomplished. The property adjoins the El Dorado mine. — At a depth of 226 ft. in the Venus shaft a good-sized body of \$30 ore has been encountered.

Searchlight, August 18.

(Special Correspondence). — A contract between the Searchlight Development Co. and the Santa Fe Mining Co., covering a term of years, provides that the latter shall supply the Development Co. with not less than 10,000 gal. of water per day, the present supply being over 65,000 gal. This abundant water-supply, added to that already developed, will provide the camp with ample fire protection. The Development Co. has contracted with the city to maintain an exclusive emergency storage tank to protect the camp against fire. — The Cyrus Noble Co. is cutting a station at the 500-ft. level. Drifts at the 300 and 400-ft. level have opened up new bodies of milling ore. The shaft is at an incline of 33 deg., so that the 500-ft. level represents a vertical depth of less than 300 ft. An additional 150 ft. is to be sunk. The new electric pump is discharging 50,000 gal. of water per day; the Duplex mine being furnished with 15,000 gal. for milling purposes. Joseph Luxon has resigned his position as superintendent of this company. His successor has not yet been named. — The Duplex Extension Mining Co. has let a contract for sinking a 100-ft. vertical shaft on the Regal claim, from which a cross-cut will be run to tap the vein traversing the John Brockman property adjoining. — The Annette Mining Co. has let a contract to sink the shaft from 55 ft. to 200 ft. — The Searchlight Mining & Milling Co. is employing more men than ever before. Twenty cyanide tanks are being put in place to treat the tailing, said to be worth \$5 per ton. Cross-cuts at water level have proved the vein to be 14 ft. wide. — Two undeveloped claims lying between the Searchlight and the Pompeii properties were sold this week by A. J. DeHaas for \$16,000 cash. The X-Ray group, of six claims and a fraction, adjoining the Pompeii, has been bonded to the United Investors Co., of New York. — Charles Gracey has resigned the management of the Wharton mines in El Dorado canyon. — A cross-cut from the south-end drift from the 100-ft. level of the Cyrus Noble Extension has been run 24 ft. without reaching the foot-wall. As soon as the foot-wall is reached, sinking for the 200-ft level will begin.

Searchlight, August 18.

NEW MEXICO.

GRANT COUNTY.

The Comanche Mining & Milling Co. is putting tables and other machinery in place in the large new concentrator just below Silver City. It is expected to have it in operation in 60 days. By this time the company will have its smelter in running order and be enabled to handle all the ores that it will be possible for them to ship from the various mines in the surrounding section. The past few months large quantities of ore have been stored in bins at the smelter.

SOCORRO COUNTY.

At the Little Fanny mine in Mogollon district, 90 miles north of Silver City, a two-compartment shaft is being sunk. It is expected to sink it to 1,000 ft. The shaft is now down about 400 ft. — The Last Chance in the same district is producing \$1,000 per day.

OREGON.

BAKER COUNTY.

(Special Correspondence). — E. A. Hutchins, who is interested in a property in Cornucopia camp, 40 miles northeast of Baker City, says the Cornucopia property has developed three ore-shoots, one 26 ft. wide, one 9 ft. and one 7 ft., all paying ore. The 20-stamp mill is running and 30 stamps are being added. Over 200 men are employed in the district, and the May Flower and Queen of the West are now on the list of producers. In the Copper Belt, between Cornucopia and Baker City, a surveying party is at the North American mine. Half way between this property and the Indiana mine, engineers are completing a railroad survey for a line known as the Oregon Central. Meantime, a road from Baker City to the copper belt is contingent on the raising of \$100,000 by the people of Baker, most of which is reported subscribed. — The North American shaft has reached a depth of 400 ft. in a deposit of sulphide ore. — The Flagstaff mine, seven miles out from Baker City, in the direction of the copper belt, has resumed work. Mr. McLane is manager. This property was recently taken over by

Boston parties. The new organization is known as the Dorothy-Flagstaff Mining Co. A trust deed has been filed here to secure bonds to the amount of \$350,000, issued by the International Trust Co., of Boston, to rehabilitate this property.—The Virtue mine, situated four miles east of the Flagstaff, which has recently been worked by W. L. Vinson, under lease, will now be operated by the Virtue Mines Development Co., which owns this property. It has contracted with the Eagle River Electric Co. for 500 h.p.—The Gold Coin mine, near Durkee, recently lost its 10-stamp mill by fire. The work of replacing it is under way. The deposit is thought to be the bottom of an old lake bed set on edge and carrying, in gravel 75 ft. wide, about \$8 per ton gold.

Baker City, August 18.

SOUTH DAKOTA.

PENNINGTON COUNTY.

(Special Correspondence).—Chas. Bishop, of California, who is reported to have purchased the Lookout property on Castle creek, five miles south of Rochford, is preparing to inaugurate work on a large scale. It is said that the mine and mill will be placed in good condition. The mill and tramways connecting with the several mine workings are fallen into decay and will require much repairing before any ore can be milled. There are excellent millsites on every side, but this mill was built on a flat, requiring a high, long and expensive trestle to reach it. There are several ore-bodies in the property, in the hills north of the mill, but some of the ore is not as free as could be desired. When this mine was worked formerly by the Lookout Co. in 1884-85, the operation was unsuccessful, due to various causes. It is thought that now, in the light of modern experience and metallurgical knowledge, success may be achieved.

Rochford, August 16.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—E. L. Tate, president of the Quilp Mining Co., is arranging to amalgamate the mines at Republic into one corporation, which will build a mill of sufficient capacity to handle the entire output. It is said that New York and Montana capital is interested.

Republic, August 18.

KING COUNTY.

James A. Moore, of Kirkland, a suburb of Seattle, has purchased the right to mine bog-iron ore on the farm of Thomas Jefferson near Arlington, and gave \$10,000 for the privilege. The analysis made was satisfactory, showing the iron ore to be of good quality.

OKANOGAN COUNTY.

(Special Correspondence).—M. A. Straight, of New York, is in Spokane, having inspected the Anonymous group on Belcher mountain. He announces that a compressor will be installed on the property, which will have capacity to supply the neighboring Golden Key and Oversight mines.—An important find of copper is reported in Spokane from Loomis, where a 20-ft. vein, rich in copper and gold, was struck on the Copper World mine, owned by Jerome Drumbheller of Spokane, and his associates. The ore was struck on the 200-ft. level. A winze is being sunk on the 300-ft. level.

Loomis, August 18.

SPOKANE COUNTY.

(Special Correspondence).—The Spokane Brokers' Association has been organized, with offices at 120 Post St.—The National Gold & Copper Co. has been incorporated at Spokane.—Other Spokane companies recently incorporated are: The Snowy Peak Mining Co., the Acme Consolidated Silver-Lead Mining Co., and the Potosi Mining Co.

Spokane, August 20.

STEVENS COUNTY.

(Special Correspondence).—Assays of the ore recently found on the Butte & Washington Mining Co.'s property

near Orient, north of Spokane, show gold, silver, and lead from \$41 to \$59. C. E. Brooks is interested in the property.—The Gold Bar Mining Co. announces that it will build a 40-stamp mill on its property near Sucker lake. Edward Staples is manager.

Spokane, August 20.

CANADA.

BRITISH COLUMBIA.

E. H. Thurston, owner of the Carmi, on the West Fork, left Greenwood Thursday with a new superintendent and crew of men to operate his property. Only five stamps will be dropped at first, but five more, now partly installed, will be added as soon as they can be got ready.—The output of the Rossland mines for the week ending August 18 was as follows: Centre Star, 2,580; Le Roi, 2,847; Le Roi Two, 467; total 5,894. Total for year, 200,893 tons. During the week ending Friday the 17 inst., the Trail smelter received the following shipments of ore in addition to those from Rossland: Snowshoe Boundary, 249 tons; Iron Mask, Kamloops, 93 tons; Snowstorm, Idaho, 78 tons; St. Eugene, Moyle, 58 tons; Ptarmigan East Kootenay, 23 tons; Paradise, East Kootenay, 23 tons.—Boundary shipments for this week were as follows: To Granby smelter, from Granby mines, 13,369 tons; from Emma 33 tons. To Dominion Copper smelter, from Brooklyn-Stemwinder, 2,903 tons, from Rawhide, 594 tons; from Sunset, 792 tons; from Mountain Rose, 75 tons. To Nelson smelter from Emma, 198 tons; to Trail smelter, from Snowshoe, 290 tons. Total shipments for week 18,254. Total shipments for year to date, 771,404 tons. Boundry smelter treatment for the week was as follows: Granby smelter, 15,250 tons. Dominion Copper Co. smelter, 4,364 tons. Total for week, 19,614 tons, total for year to date 769,968 tons.

The Tyee Copper Co., at Duncan's Station, Vancouver Island, reports smelter returns for July as follows: Smelter ran 11 days and treated 1,792 tons of Tyee ore, giving a return, after deduction of freight and refining charges, of \$31.128.

MEXICO.

SONORA.

It is reported that the Greene Consolidated Co. of Cananea recently shipped 300 Chinamen from Guaymas to Cananea, where they are now working in the mines. They were brought over the railroad to a station below Nogales, and were taken across the country from that place to Cananea. It is said that the Greene Co. is short of miners, as many of the Mexicans heretofore employed there have left.

Trade Treatises.

THE ALLIS-CHALMERS Co., of Milwaukee, Wis., has issued bulletin No. 1,505 describing the Allis-Chalmers heavy-duty engines of the belted type.

PERCY PITMAN, of Rosbury, Ledbury, England, manufacturer of Hector water motors, multiple-nozzle impulse wheels, and combined turbine-dynamo charging sets, has issued catalogues and circulars descriptive of these types of machinery, and will send the same on request.

ATLAS ENGINE WORKS of Indianapolis, Ind., has issued a handsome Bulletin, No. 131, descriptive of throttling and automatic single-valve engines. It is clearly and handsomely illustrated. This company also makes a four-valve engine which it is claimed meets every requirement of power users.

THE ordinary gravel-roofing is formed by first covering the surface of the roof with dry felt (paper) and over this laying three, four or five layers of tarred or asphaltic felt, the layers of felt lapping over each other like shingles, so that only from 6 to 10 in. of each layer is exposed. Flashing against walls, chimneys, curbs of skylights, etc., is done by turning the felt up 4 in. against the wall. Over this is laid an 8-in. strip with half its width on the roof. The upper edge of the strip and of the several layers of felt are then fastened to the wall by nailing wooden strips or laths over the felt and into the wall.

Personal.

CHARLES BUTTERS is at Carlsbad.

W. H. SHOCKLEY has gone to the Yellowstone Park.

J. TROWBRIDGE BAILEY has returned to New York from Brazil.

GEORGE W. MYERS has returned to Berkeley from Alaska.

E. W. SEBBEN, of Denver, is examining several mines in Arizona.

F. F. SHARPLESS has returned to New York from British Columbia.

H. A. GUESS is manager of the Silver Lake mines at Silverton, Colorado.

ALVIN B. CARPENTER, of Mexico City, is examining El Bote mine at Zacatecas.

W. H. SHOCKLEY, now residing at Tonopah, has been on a visit to San Francisco.

JAMES F. KEMP sailed from New York on August 23d, on his way to Mexico City.

S. F. EMMONS visited Denver on his way to the Geological Congress at Mexico City.

WILLIAM TENNER, of Los Angeles, has been inspecting mines in Sierra county, California.

VICTOR M. BRASCHI, of Mexico City, attended the American Institute meeting in England.

ARTHUR M. BREWSTER, manager of the Vivache mine in Oaxaca, Mexico is visiting New York.

DU RAY SMITH, of Oakland, Cal., owner of the Primrose mine in Sierra county, recently visited the mine.

SAMUEL JAMES has resigned as superintendent of Los Arcos Mining & Smelting Co. at Sultepec, Mexico.

W. A. ALLEN has been appointed superintendent of construction at the new San Bruno smelter, San Francisco.

GEORGE W. BORROWE has been appointed general manager of the Gt. Boulder Perseverance mine, at Kalgoolie.

M. K. RODGERS was recently at Catella, Alaska, inspecting mining property, and looking over a proposed railroad route.

W. P. SAWYER, of Nevada City, Cal., principal owner of the Herkimer mine, in Sierra county, has been at the mine for a week.

W. A. CLARK, JR., accompanied by JOHN A. RYAN, has been in the Cœur d'Alene district several days looking over the Clark properties.

B. HUTHOFF, formerly manager for 12 years of Mohler Bartning Sucs., Mazatlan, has established a general commission business at 110 Battery street, San Francisco.

W. A. KUNKLE, superintendent of the Silver Lake mill, at Silverton, is making a trip through the different mining camps of Colorado and other States in order to investigate recent improvements in ore dressing.

WILLIAM A. POMEROY has recently been re-appointed general manager of the Palmarejo & Mexican Gold Fields, Ltd.; he has also been made consulting engineer to the Oxnham Prospecting Co. (No. 1), Ltd., at Chinipas, Chihuahua, Mexico.

HENRY STANLEY RENAUD, of Waller & Renaud, consulting chemists at 159 Front St., New York City, has recently been admitted to the Bar of the State of New York as an attorney and counselor-at-law. In connection with his work as consulting chemist, Mr. Renaud will devote his attention to chemical, techno-legal, chemico-legal, lego-mining and patent cases.

Obituary.

SAMUEL LEWIS PENFIELD, head of the Department of Mineralogy in the Sheffield Scientific School of Yale University, died at Woodstock, Conn., on August 14, aged fifty years. He was one of the highest authorities on the determination of minerals, and, as the author of several useful books on the subject, he was well known to mining men.

WILLIAM OXNAM died at Los Angeles on August 16. He was suffering from tuberculosis when he went to Los Angeles from Mexico in March. For two years he was superintendent of the mines of the Palmarejo & Mexican Goldfields, Ltd., at Chinipas, in Chihuahua, and later, manager of the Oxnham Prospecting Company.

A. MCCHARLES, a well-known mining man of Sudbury, Ontario, died at Montreal on the 5th inst. He was a native of Cape Breton, Nova Scotia, but came to Ontario in 1855 when quite young. He taught school and was engaged as a traveling salesman during the early part of his life, subsequently doing pioneer work in the West. He was latterly largely interested for many years in prospecting and mining operations in the Sudbury nickel region and took a very active part in the agitation for more liberal mining laws.

THOMAS S. AUSTIN, general superintendent of the Southern Department of the American Smelting & Refining Co., died of diabetes at El Paso, on August 22. Born at Stratford, Conn., about fifty years ago, and graduated from the Columbia School of Mines, T. S. Austin was one of the most successful smelter managers in the United States. The sudden end to a career of notable usefulness will be much regretted by his friends at Leadville, Salt Lake City, Socorro, and El Paso, at all of which places he successively held important positions as metallurgist. He leaves a wife and a young daughter; among the technical men he is survived by his elder brother, Professor L. S. Austin, and two nephews, J. F. Austin, superintendent of the Monterey smelter, Mexico, and Arthur Austin, who is at the Washoe plant, Anaconda.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

A 10-STAMP MILL on the Kalgoorlie field of Western Australia, has gravity stamps weighing 1,750 lb. each.

CASSITERITE occurs as a replacement of topaz in the granitic rock of Mount Bischoff in Tasmania.

COVELLITE is not a common ore. It rarely occurs crystallized, being usually massive and of dark indigo blue color.

A TRIANGLE having two sides of 7 each and one side of 9.9 has approximately one angle of 90 deg. and two 45 deg. each. This is near enough for all practical purposes.

THE difficulty which men have of conceiving the aggregate effects of causes which have operated throughout millions of years, far exceeds all sources of prejudice in geology, and is yet the most unphilosophical of all.

MOLYBDENUM and titanium produce fast shades on leather. Molybdenum tannate has a great affinity for animal fiber. It is a deep yellow color, but a large variety of shades can be obtained by employing it in connection with logwood extracts.

WE would suggest that our Ketchikan, Alaska, correspondent communicate with Mr. Thos. A. Edison himself, or with Stanley Jordon & Co., 100 William St., or Louis Straus & Co., 60 New St., both in New York, who are buyers of cobalt and nickel ore.

THE crushing strength of granite is variously stated to be 12,000 to 20,000 lb. per sq. in., the tests being made on two-inch cubes. Solid granite not altered by weathering or other influences, weighs 165 to 170 lb. per cu. ft. according to the amount of iron-bearing mineral present.

IF greater hoisting capacity is required, it is better to increase the size of the skip or car than the speed of the hoisting engine. If the engine cannot hoist a somewhat larger load, it is also incapable of faster running, and the limit of its economical operation has probably been passed.

LITMUS is a peculiar coloring matter obtained from certain lichens, which are subjected to maceration with lime, soda, or potash and other chemicals. Upon fermentation the mass becomes blue. Paper tinted blue with litmus turns red when coming in contact with an acid, and blue litmus paper is consequently used as a test for the presence of an acid.

IN the gold mines of the Rand a new discovery, or new development of an old discovery, is being watched with interest. It is a lode of quartzite impregnated with auriferous pyrite, and lying in the foot-wall country of the Main Reef. This lode has been found by cross-cutting in a number of mines and is being sought in others. In one of the mines this lode is said to be eight feet wide assaying over \$10 per ton. In some others it is too low-grade to pay.

A NEW diamond mine is being worked near Kimberley, South Africa, by the United South Africa Association and others. The property is known as the Paardeberg East Mines, and results are said to be satisfactory. The quality of the stones is reported as exceptionally good. Operations have been carried on in the past on a fissure vein. It is stated that the main deposit has

been found in another part of the property where work is now proceeding.

AN instance of the cost of hydraulic mining in California is cited by W. E. Thorne in Trans. A. I. M. E., 1902. This was in El Dorado county, California, and the cost was \$0.183 per cu. yd. The conditions were exceptional as the deposit was in a narrow canyon, and only 7 to 23 ft. deep, consisting principally of tailing from seam diggings that had been hydraulicked. The mine discharged into a tributary of the Sacramento river, and thus came under the rules of the Debris Commission. The cost of restraining dams alone was 3c. per cu. yd. of gravel.

IN laying out foundation and other superficial work without instruments, workmen sometimes make use of the fact that the sides of a right-angled triangle have a positive relation to each other. Thus, for instance—having laid out one straight line, a second line may be established at an absolute right angle to it by measuring off on the first line accurately eight feet, then measuring carefully in a diagonal direction to the second line a distance of 10 ft. When this second measurement touches the second line at exactly six feet from the corner, the two lines form an exact right angle.

WHEN arsenical ore (mispickel) is being treated in the stamp-mill by amalgamation, the greatest care must be exercised or the gold will be saved with difficulty. Inside plates should be used, and the quicksilver feed watched. Too much quicksilver softens the accumulated amalgam, causing any that may have accumulated on the plates to scale off allowing it to pass out of the mortar through the screen, when it may be lost, or at any rate give additional trouble in its recovery. If too little quicksilver be fed, the plates become spotted and require much otherwise unnecessary dressing. For ore of this character the copper should be plated with not less than four ounces silver per square foot of surface.

INSIDE amalgamation in mortars, or mills of any type, is always advisable where possible. The object of amalgamation is to recover gold from ore, and the sooner this can be accomplished after the ore has been crushed the better. If feeding excess of quicksilver causes the lower end of the outside plates to drip, feed less in the battery and give particular attention to the upper outside plate, endeavoring to catch any amalgam there that may escape through the battery screens. The probability is—in the Siskiyou county, Cal., instance—that the outside plates are not wide enough. With broad plates, properly dressed, the lower portion should not drip. Dress the plates from the lower end toward the mortar, and avoid feeding excess of quicksilver at any time.

IN providing a pumping plant for a mine, we must first fix upon the vertical height or lift of the pumping apparatus, and the quantity of water to be raised daily, as determined by proper measurements. There must be ample reserve capacity for emergencies; this point must be most carefully considered, as upon it may depend the security of the mine against flooding. Next we must consider the commercial efficiency of the installation, having regard to first cost as well as to economy of working. One would naturally put in a cheaper and more wasteful pump if the plant is to be in use for a shorter time. Where a large quantity of water is to be raised it is often well to put in pumps in duplicate, one of which will handle the water under normal conditions, so that, in case of flooding, both can be run. The life of such a plant is greater than in a single-pump plant which has to be continuously operated.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Gold and Pyrite.

The Editor:

Sir—I have read with much interest the valuable article by Professor Henry Lloyd Smith on the relations between gold and pyrite, which appeared in your number of July 14. An illustration is given of the manner in which the gold is concentrated in the pyrite in quartz veins, while the pyrite in the adjoining country rock is poor. Certain experiments described also seemed to prove that a secondary enrichment of gold had taken place.

That pyrite in quartz veins is, as a rule, richer in gold than pyrite in the immediately adjoining country rock is a generalization now universally accepted by students of mineral deposits. Becker probably was one of the first to recognize it, but statements confirming this law may be found in any of the more recent reports dealing with gold-quartz veins. The distinction drawn by Professor Smyth between the pyrite in the quartz and that in the country rock should perhaps be slightly modified. It is true that the latter is often formed by replacement of some iron-bearing mineral, but this is by no means necessarily the case, as shown by an abundance of pyrite sometimes replacing wall-rock very poor in iron.

The generalization referred to would read as follows: A vein-forming solution containing silica and gold will deposit the bulk of its silica and gold in open spaces, *if these are available*, and very little of either constituent will, as a rule, permeate and replace the adjoining wall-rock. The reason for this is, no doubt, that the silica is in colloid solution which is closely held by the semi-permeable wall-rock, which, on the other hand, is easily penetrated by solutions of ordinary salts, in accordance with well-known laws of physical chemistry. This also explains the rare occurrence of silicification of wall-rocks adjoining quartz veins. In some way the gold and, to a less degree, the other heavy metals, are held with the silica, perhaps also in part in colloid solutions; it is not denied that solutions of heavy metals may freely penetrate many porous rocks, but it seems certain that they will not do so if fissures are available, and if there is no strong chemical affinity between the rock and the solution. The poor pyrite in the wall-rock and the rich mineral in the vein were deposited practically at the same time and by the same water.

Secondary deposition of gold in veins is a mooted subject; it must certainly be confessed that compared to that of easily soluble metals, such as copper and silver, the secondary deposition of gold is a very rarely occurring phenomenon and involves very slow reactions. I admit having some doubt about its occurrence except in a few unusual cases; the evidence which Professor Smyth brings in favor of his case seems far from being convincing.

WALDEMAR LINDGREN.

— Denver, August 9, 1906.

Misuse of Cement.

The Editor:

(Sir—Some time ago the foundation for a heavy stamp-battery was constructed of concrete made by mixing very dirty sand with too small a proportion of cement. The concrete was placed spasmodically, several days sometimes intervening between layers. The stamps are now dropping and the cement layers are separating, with the result that cement foundations are considered unworthy at that plant. The concrete can be whittled with a pocket-knife and is hardly better than lime mortar. The

size of the mortar-block was much reduced from the print supplied by the designing engineer, but very shortly the opponents of cement mortar-blocks will point with pride to this installation and say: "I told you so!"

MARK R. LAMB.

Goldfield, Nev., August 11, 1906.

The Treatment of Desert Ores.

The Editor:

Sir—I have been interested in the discussion by Mr. Bosqui and Mr. Hunt relative to the treatment of desert ores. As I have recently been required to devise a method of treatment for the ore of one of the mines near the Combination, at Goldfield, the following may be of interest.

The material is typical of the Goldfield district, but was the lower grade 'milling ore,' averaging about \$20 per ton. When the samples were brought to the laboratory I was requested to make 'amalgamation, concentration and cyanide test' to determine the best possible extraction obtainable. The test gave the following results: Recovered by amalgamation, 32%; by concentration, 16.5%; and by cyanidation of tailing, 46.5%, making a total recovery of 95%.

The concentrate was very high grade—being over \$500 per ton—and represented $\frac{1}{2}$ % by weight of the ore taken. After completing this test, I decided to try direct cyaniding of the ore after dry-crushing the whole of it to 100 mesh, with the result that I obtained 94% extraction. After confirming these results by further tests, I recommended the following general method of treatment: Dry-crushing to 12 or 16 mesh, fine grinding in tube-mills with cyanide solution to 100 mesh, agitation and filter-pressing.

The direct treatment of this ore by cyanide would have many advantages over the usual custom of amalgamation and concentration followed by cyaniding. In the first place water is very scarce; in the ordinary stamp-mill practice water is used in the ratio of from four to seven parts by weight to one of ore. In following the idea suggested above, it would be necessary only to use a sufficient amount of water as cyanide solution to get the best results from the tube-mill, and agitation tanks, and for washing in the filter-presses. According to Mr. Butters, El Oro practice shows that the proportion of water to ore used in tube-mills should be one to one, or less, to obtain the greatest efficiency. The plant would cost much less to install than the usual stamps and concentrators with sand and slime cyanide-annex; and, requiring but one crew of men, it would reduce the operating costs materially. I doubt the advisability of treating the majority of ores in both sand and slime plants; such plants in my opinion being suitable only to tailing piles where the crushing has already been done. In most ores if a plant is necessary to treat the slime when crushing coarse, it will pay to slime everything and treat altogether—thus combining all the work in one plant with one crew. Nor do I believe in the other practice—except in rare cases—of crushing all the ore to a 200-mesh slime. Those who have had to operate filter-presses or filtering devices realize the difficulty of filtering, washing and removing cakes of 200-mesh slime; while if all the ore is crushed to 100 mesh, agitated as one product and filter-pressed, the extraction is not materially reduced, save in exceptional cases, and the cakes can be made thicker and dryer, and are easily washed and removed. In fact, some of the new presses are so constructed that material of this kind can be filtered, washed and sluiced out automatically without entailing the expense of opening the presses between each change. This is not possible with a very fine slime, which becomes as tenacious as India rubber and must be almost chiseled from the cloths. In

the majority of cases the mill clean-up will show a greater extraction than if all is crushed to pass 200-mesh; the possible exceptions are sulphides or perhaps a clean silicious ore, free from argillaceous material.

Mr. Bosqui, in advocating wet crushing and amalgamation, mentions the "great advantage of being able to secure daily from plates 50% of the extraction obtained from \$50 ore, as compared with waiting for the tedious monthly or bi-monthly clean-up in a cyanide plant." I confess that I cannot see this advantage. Crushing 60 to 75 tons per day and recovering \$25 per ton would be but \$1,875 per day at most, and surely he would not make a melt every day for that amount. A bi-monthly clean-up would amount to but \$28,000, which is not an unusual clean-up even in our California mills. A cyanide plant, if properly designed, can be roughly cleaned up every ten days without any great inconvenience; to be followed by a complete clean-up, say once a month. I must agree with Mr. Hunt regarding the practicability of crushing dry to any required fineness, as instanced in cement mills, but that is not necessary. It is my belief that the time will soon come when nearly "every new modern mill operating upon a logical basis" on the deserts will be so constructed that crushing to 10 or 16 mesh will be done dry by breakers and rolls or ball-mills, and the whole product will then be mixed with cyanide solution of a strength sufficient to obtain the highest extraction and passed through tube-mills or some other device to reduce to a fineness of 100 mesh; that the product will all be agitated together and passed to filter-presses so constructed as to permit of automatic discharging.

The objection to dust, I think, will be overcome as it is in the cement mills of Europe, where the laws compell the installation of exhaust-fans and dust-collectors. In a plant such as I have roughly outlined, the dust could be conveyed by pipes connected with an exhaust-fan to a hopper, where a spray of cyanide solution would collect and carry it to be mixed with the tube-mill product. Such an arrangement would be efficient, and the cost of installing and operating would be trifling.

Another point which I think is generally overlooked is that the coarse gold in any ore when subjected to the grinding action of the tube-mill or any other machine necessary to pass it through a 100-mesh screen, will cease to be coarse gold. All of us know how brittle gold becomes even upon rolling, as is seen in assaying bullion when rolling out the cornets, which, unless repeatedly annealed, will break to pieces. This same action occurs in grinding the ore and is aided by the sand grit, so that by the time the ore passes 100 mesh, practically every particle of gold is a very fine scale, a most ideal condition for cyanide attack.

Crushing to 10 or 16 mesh, no matter how hard the rock, is done cheaper in breaker and rolls dry, than with breakers and stamp-mills wet. The cost of installation per given capacity is less, and in desert regions, where water is of itself such a problem, the dry-crushing method must appeal to both the manager and the metallurgist.

I think it is becoming generally recognized that fine grinding of the whole product to 100 mesh increases the profits, and when this is so I do not think amalgamation should play any part in the process, except possibly in very rich (over \$100) coarse gold ores. The stamp-mill as an amalgamator and when crushing to 30 or 40 mesh has long held its place in the first rank, and for that purpose can hardly be replaced. But its success in this line seems "by the compelling force of custom" to lead metallurgists to its adoption in all cases. But new conditions have been presented. We no longer want a 30 or 40-mesh product, but a 100-mesh. Therefore, let us adopt the machines best suited to these new conditions.

Oakland, August 1.

LOCHIEL M. KING.

Induction-Motor Hoists.

The Editor:

Sir—I read with much interest Mr. C. F. Lehman's article on an 'Induction-Motor Hoist,' and I desire to acquaint the readers of your paper with another method of gaining smooth acceleration for heavy hoisting duty in connection with induction-motors. The motor is connected directly to a Cutler-Hammer magnetic accelerator clutch; this clutch is adapted to be placed on the motor-shaft where the usual pinions are used, or attached. The best arrangement is to have the accelerators attached to the motor and the pinion with accelerator-disk on a separate mandrel in line with the rotor-shaft of the motor. This necessitates setting the motor a little further to one side than is usual. This clutch is energized through two small collector-rings on the induction-motor shaft through a small direct-current generator attached to the end of the induction-motor shaft. The motor used can be of constant speed type, and is kept constantly floating in the mains. In series with these accelerators a speeder is used, which is nothing more than a common field rheostat; by gradually increasing the magnetic flux in the accelerator, the load is gradually picked up without any disturbance in the voltage on the lines. This is a very important factor when investment in copper and generating capacities are limited. The direct current consumed is 10 watts per horsepower transmitted by the clutch. The above method is efficient and the operator cannot become confused, as he only has his brakes and speeder to manipulate. These accelerators are also being used to a large extent in driving. Air-compressors are used in conjunction with a pressure-governor. Whenever the pressure exceeds a predetermined amount, the governor inserts resistance into the speeder, which reduces the magnetism in the accelerator and allows the speed of the compressor to fall off, likewise it increases the speed of the compressor to maximum, as the pressure is reduced. By the above arrangement you are never blowing off, and it will readily be seen that by the use of these accelerators constant-speed polyphase induction-motors can be used to advantage and still retain all the desirable features of a variable-speed drive.

FRED P. DE WILDE.

Spreckels, California, August 5, 1906.

CRYSTALLIZED DOMEYKITE.—The natural mineral, a copper arsenide, containing 70% Cu and 30% As, upon exposure to the air changes from its normal yellow color to purple and blue on the faces of its brittle crystals. Dr. Koenig, in *Proceedings American Philosophical Society*, June 1, 1903, describes his method for the production of these crystals by the action of the vapors of arsenic upon a stout copper wire. On account of the growth of these crystals upon the copper wire he has named his apparatus an incubator. It consists of a closed tube 0.75 in. diam. containing 5 to 10 grams of arsenic, then a loose asbestos plug, and finally a wire 0.25 in. diam. and 2.5 in. long. The exterior of the tube was wound with platinum wire, which formed an electric resistance, and by which the wound portion of the tubes could be maintained at a high and steady heat. At this temperature the arsenic was sublimed, and the vapor thus formed, came in contact with the copper wire, which largely took up the arsenic, thus forming the artificial copper arsenide crystals.

PROF. CHAS. L. NORTON, of the Massachusetts Institute of Technology, gives the heat units, of various kinds of fuel, obtainable for one cent, as follows: "Coal, \$12 per ton, 23,000; wood \$10 per cord, 27,000; oil, 12 cents per gallon, 12,000; coke \$10 per ton, 24,000; gas, \$1 per 1,000 cubic feet, 6,500."

Gold Dredging in the Urals.

By WILLIAM H. SHOCKLEY.

*The Lozva river is a clear-water stream flowing from an altitude of 4,000 ft. and through a densely wooded country; it is navigable for good-sized steamers as far as Ivdell. Temperature ranges from -60 deg. F. in winter (early November to late April) to 90 deg. F. in summer. Rainfall is 20 inches. Communication is over the new railway from St. Petersburg through Viatka and Perm to Goroblagodatskaia, thence by branch-railway to Bogoslovsk, and by post-horses to Ivdell; north of this, travel is by boat in summer and reindeer-sledge in winter.

Ten dredges are at work and eight more are under construction. These were all to have been at work by the present summer, but political trouble has prevented. The Sans Galli Co.'s dredge (Bucyrus) is working in a swift stream near Nijni Tura. It digs 1,200 yd. per day and should in a season take out 60,000 rubles† or \$30,000 at a cost of \$15,000. Bedrock is hard slate, and boulders up to 300 lb. occur. Two iron pans 15 ft. diam. with revolving arms disintegrate the clay. The buckets fill one pan and outlet of other is closed to allow cleaning of material. A gate shutting off the pan-feed and an iron chute directing the material to the tailing-belt were used, but the water washed the dirt back on the belt. This was overcome by using the pans.

Two dredges of the New Zealand type on the Lobva river cost \$45,000 and \$25,000, respectively. The pontoon of the first is iron, and of the second, wood. Working expenses for two months for one of these was \$2,065.80.

This dredge was built in the winter of 1904-5 in a pit on the river-bank. During the construction, chips, shavings, hay, and manure from the teams employed in hauling the dirt, covered the ice in the pit, and, by protecting it from the sun's rays, retarded the spring thawing a full month. During this delay, the river fell 10 ft. lower than the dredge. Instead of digging a diagonal canal to the river the pit was deepened vertically and the tailing was removed by teams. Another month was occupied in this work, giving a total loss of two months, due to bad management.

At Bogoslovsk, 1,663 prospecting shafts, of an average depth of 12.25 ft., cost \$8.50 each, equivalent to \$0.70 per ft. In Alaska, similar shafts cost from \$3.50 to \$8 per foot.

Neither of the two dredges on the Lobva river yielded any profit during 1905, although the gravel carried 16c. per cu. yd. In 1904, the Bogoslovsk estate began work with a Neviansk dredge of the New Zealand type on the bed and banks of a small sluggish stream, having a total width of 200 ft. The gravel is soft for a depth of 14 ft., with 5-ft. pay-dirt. This company is building two similar dredges of the New Zealand type, somewhat improved by a study of illustrated catalogues and of the Bucyrus dredges working in the region. A Neviansk dredge on the Sosva river, 60 miles north of Bogoslovsk, stuck on a rock at the beginning of the season, and in three months produced only 1.5 lb. gold.

The most successful work is being done at Ivdell, where a Bucyrus dredge built by the Putiloff works under the supervision of H. L. Lawson, an American dredge-master, was operated almost without a stop during its first season in 1905. Fig. 1 is a photograph of this dredge, which shows the steep banks of the river in the background. It has dredged nearly a mile of the Ivdell river, a swift stream 200 ft. wide, flowing through

a limestone formation. The amount excavated daily is estimated at 1,500 cu. yd. The cost of the dredge, complete, including a Keystone drill and some prospecting work, was \$70,000; and the profit for 1905 is estimated at \$32,500. A duplicate dredge, estimated to cost \$50,000, is under construction. On all these dredges, tables are used to save the gold; the Ivdell dredge has shaking screens; the others, revolving trommels.

COST OF OPERATING THE DREDGE AT IVDELL.

	Per month.	Total.
3 pilots	@ \$37.50	\$112.50
3 machinists	@ 37.50	112.50
3 firemen	@ 15.00	45.00
3 oilers	@ 20.00	60.00
2 woodmen	@ 17.50	35.00
2 clean-up-men	@ 12.50	25.00
1 blacksmith	@ 20.00	20.00
1 goldwasher	@ 15.00	15.00
1 dredge-master (American)	@ 180.00	180.00
Wood	@ 150.00	150.00
Total		\$755.00

The maximum expense per month, including repairs and all materials used, is thus estimated at \$1,500.

The following conditions should be assured:

1. The work should be under charge of an American or New Zealand dredge-master, who has had experience in cold countries. This is a vital point. The Russian engineers, though well educated and intelligent, are poor managers.

2. Extensive prospecting is needed and can best be done in winter, by sinking shafts on the Siberian system, that is, allowing the water to freeze, sinking a short distance, waiting for the water to freeze again, and eventually reaching the bed of the river, even through running water. This method sometimes fails in the Urals, owing to unfavorable weather, or the presence of warm springs. Hand-dredges, worked by parties of six men or of three men and a woman (see Fig. 2), and washing a few yards daily are useful for prospecting river beds. A Keystone drill should be used on the river banks by every dredging company. In most of the Ural rivers the richest gravel seems to be in the bottom, the banks being poor.

3. A small dredge, run by steam or horsepower and costing complete not more than \$5,000, would do good work on these rivers.

4. Dredges should be built on the bank and launched, in order to avoid the expense of a pit; wooden pontoons should be used.

5. If prospecting work shows that there is much clay in the gravel, the enterprise had best be abandoned, because no method of dredging has yet been devised that will handle successfully material of this character.

6. The gold, which is uniformly coarse, should be saved in iron-lined, wooden sluices, and not on tables. These sluices should be 120 ft. long, like those used in Montana. Nuggets which pass over ordinary tables can be saved in sluices. Repairs to sluices are trifling compared with the expense of keeping up the belts of tables. Moreover, in a cold climate, a sluice can be operated for a number of days longer than a belt or a bucket-elevator. The water flowing in a large stream does not freeze so readily; and hence it is not necessary to shut down when the first cold snap comes.

7. Grizzlies should be provided to remove the large stones, which should first be washed.

8. Two boilers are needed, steam being kept in one while the other is being cleaned. In this way less time is lost; and the extra boiler is also useful for other purposes. All driving shafts should be bored longitudinally, so as to allow an obstinate wheel or gear to be loosened for removal by heating, the shaft being kept cool by a stream of water flowing through it.

9. For swift rivers, buckets three cubic feet capacity are large enough. These should be closely set, and should excavate from 1,500 to 2,000 cu. yd. daily. For a dredge

*Abstract from July issue of Bi-Monthly Bulletin, Trans. A. I. M. E.
†One ruble is worth 50c. United States. We have converted the Russian currency into American money throughout this abstract.—Editor.

of this capacity, the following engines are advised: 60-h.p. for digging; 60-h.p. for 14-in. pump; 15-h.p. for swinging; 15-h.p. for trommel; 15-h.p. for elevating tailing (not needed if sluice is used); and 20-h.p. for electric light.

10. For swift streams, spuds are preferable to head-lines for holding the dredge in place. The top tumbler-

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

The rocks from Chilpancingo, Mex., are: No. 1, a much-altered intrusive rock, apparently Aplite; No. 2, typical quartz-porphry; No. 3, a very silicious phase of Aplite (Alaskite); No. 4, an intimate mixture of lead and zinc sulphide, which probably contains gold and silver. A little pyrite can be distinguished, and arsenic and probably antimony are also present. It is one of those complex sulphide ores for which Mexico is noted. No. 5 is Rhyolite; No. 6 is silicious Diorite, containing pyrite and chalcopyrite.

The rocks from Beatty, Nevada, may be described as follows: The unaltered piece is typical Rhyolite in which appear quartz blebs and crystals of sanidine (glassy feldspar), and a few black hornblende crystals are also seen. The flow structure is readily seen when magnified a few diameters. The soft piece is com-

posed of fragments of the same kind of rock as the first,

due to crushing of the rock mass, and may be from either a zone of fissuring and movement, or from a por-

shaft should be adjusted to move without difficulty. The mineral resources of the Urals are very great, and there is an immense field for dredging in the Russian Empire. When the present political troubles have passed away, the industry will exhibit a rapid development. The Russian laborer is good, considering his wage; and the officials, although sometimes troublesome, yield to tact and other influences.

AN ingenious method of separating the heavier metalliferous minerals from gangue is thus described in a recent patent: "The pulverized ore is thoroughly mixed with soap solution and the mixture treated with a mineral acid, when the fatty acids thus precipitated carry down the heavier metalliferous constituents, while the gangue is washed away. The residue is then treated with caustic alkali, when the soap solution is regenerated and the heavy minerals obtained. The soap solution may be replaced by alkaline solutions of crude carbolic or cresylic acid, or even by a solution of tar soap."

DARWIN said that geology was "an excellent science to begin with, as it requires nothing but a little reading, thinking and hammering." That is all any science or industry needs—and it is a great deal!

tion of the mass which has been crushed locally. It is Rhyolite-breccia. The crushing of the rhyolite has resulted in a greater or less alteration of the feldspathic mass to Kaolin, the larger fragments being little, or not at all altered. The presence of iron oxide suggests the occurrence of secondary pyrite and therefore of gold.

Fig. 2.

Fig. 1.

Copper at Butte, Montana.---III.

Written for the MINING AND SCIENTIFIC PRESS
By ARTHUR H. HALLORAN.

The Butte & Boston Co. operates the Gray Rock, Silver Bow No. 1, and Berkeley mines, 1,000, 1,600 and 800 ft., three-compartment shafts, respectively. A Reidler pump on the 1,000-ft. level of the Silver Bow No. 1 can pump 800 gal. per min. to the surface. A 28-drill Nordberg compressor furnishes air for the Gray Rock. A new shaft is being sunk on the Tramway mine by the Red Metal and Butte & Boston jointly, which, when completed, will be used by both companies. Both own interests in the Tramway and Snohomish mines, and the Red Metal owns the Minnie Healey, which adjoins the Tramway and Snohomish.

The Trenton Mining & Milling Co. is operating the

Clear Grit main two-compartment shaft is 600 ft. deep, with a 250-ft. winze. A $\frac{7}{8}$ -in. round rope and bucket are used in hoisting. The two-compartment Cambers shaft is 200 ft. deep and employs a single-deck cage and 1 in. round cable for hoisting.

The Rarus, Minnie Healey, Belmont and Corra are classed together, because formerly owned by the Montana Ore Purchasing Co., now under the Red Metal Mining Co. They are closely associated with properties already described and are to be operated in conjunction with them. The Rarus and Minnie Healey shafts are three-compartment and 1,500 and 1,100 ft. deep. The Corra has two compartments for 800 ft. and three compartments for the remaining 1,000 ft. It is being sunk 400 ft. deeper. The Belmont has two compartments 900 ft. deep; it is to be deepened and used to work a part of the Anaconda mine. The Rarus pumping plant comprises one 500-gal.

High Ore and Mountain View Mines.

Gagnon mine. The shaft is inclined, has three compartments and is down 2,000 ft. Double-deck cages are used for handling the men, changing to three-ton skips for hoisting rock. The water is pumped by two Aldrich electric pumps, one with a capacity of 100 gal. per min. on the 2,000-ft. level and the other 200 gal. per min. at the 1,000-ft. level.

The Parrot and the Original No. 6 mines are being worked by the Parrot Silver & Copper Co., of which H. A. Gallway is manager and Dan. Griffin foreman. The Parrot three-compartment shaft is being sunk to 2,400 ft. The Original No. 6 two-compartment is down 1,000 ft. At the Parrot two double-deck cages, with ten-ton skips attached, hoist the ore and dump it automatically into the bins at the surface. An 80-drill Ingersoll-Sergeant and a 20-drill Rand compressor are in use.

The Washoe Copper Co. operates the Moonlight, Clear Grit and Cambers mines, doing most of their work at the Moonlight. The main shaft has three compartments and is 1,300 ft. deep. A 20 by 48 in. Dickson engine, with 6-in. flat cable, hoists two double-deck cages. The

Worthington on the 800, one 420-gal. electric pump and a 500-gal. Jeanesville pump on the 1,300, a 500-gal. Knowles and two 250-gal. Camerons on the 1,400, and two 200-gal. Cameron sinkers in the shaft. Double-deck cages, with skips attached, and Webster, Camp & Lane hoists and flat cables are used at all the shafts except the Belmont.

The Lexington mine, a Heinze property operated by La France Mining Co., is said to have been transferred to the Butte Coalition. The main shaft is down 1,450 ft. A new Allis-Chalmers 20 by 60 in. cylinder-hoist, using a $1\frac{1}{2}$ in. round rope and double-deck cages, is being installed. An 800-gal. centrifugal and two 400-gal. Aldrich pumps are expected to handle the water. It is likewise reported that the Alice mine at Walkerville, an old silver producer that shows copper at depth, has been transferred to the Butte Coalition. It has been mined to a depth of 1,500 feet.

The North Butte Mining Co., A. C. Carson, manager, is working the Speculator, Edith May, and Jessie mines through the Speculator shaft. This is down 1,600 ft.,

with three compartments, and has recently been re-timbered and has been connected at the 1,600-ft. level with the old Jessie shaft. This was originally down 330 ft. By sinking a winze 500 ft. and by raising 470 ft., the shaft was completed. A Nordberg engine, similar to

sides and loading is done from but one side of the shaft. A 32 by 72 in. Nordberg engine and 1½ in. round cable is used. In square-setting the stopes both round and square timbers are used, the round for posts and girts and the square for caps. Round timbers are larger at one end

Western Portion of Walkerville, a Suburb of Butte. Alice Mill and Mine in the Background.

that at the Leonard, and a new head-frame 127 ft. high, are now being completed. The company is also developing the Carlisle and Protection claims. This company is working farther north than any other copper producer; to its recent phenomenal success may be ascribed the for-

than at the other and give uneven floors. The square caps give good floors and catch the girts better. With the round caps the flooring is more apt to slip off than with the square caps. A number of accidents have been caused by planks sliding off round caps. The West Stew-

Belle and Diamond Mines.

mation of the numerous new companies during the past few months.

The Original Mining & Smelting Co. is working the Original and West Stewart, W. A. Clark's properties, of which A. H. Wethey is general manager and Thomas Bryant superintendent. The Original shaft is down 2,200 ft., two compartments for 700 ft. and three compartments for 1,500 ft. Two double-deck cages with seven-ton skips are used. Sheet-iron sides inclose the cages on three

art, down 1,900 ft., has a hoist similar to the Original. Tramming is done with horses and men. A 60-drill Ingersoll-Sergeant compressor furnishes air for both mines. Steel head-frames are above the shafts.

A. J. Coram and associates, of Boston, own a large number of claims in the centre of the town south of the Amalgamated properties. These are now being opened up by the Davis-Daly Estates Copper Co., which has given a contract to the Original Mining Co. to run a

cross-cut 3,500 ft. from the 1,800-ft. level of the Original mine. A shaft will be sunk to connect with the southern end of this cross-cut. Another shaft will be sunk on the Hesperus and a cross-cut driven north.

Out on the flat, east of Butte, the Pittsburgh & Montana Mining & Smelting Co. has been working a number of narrow high-grade veins. To reach these, the shaft had first to be sunk through 600 ft. of wash. The Pittsburgh & Montana Co. has two shafts, the Farrel No. 1 and 2, each down 1,200 ft. No. 1 shaft is at the smelter, No. 2 half a mile north, and all the property, surrounded by a 12-ft. black fence, is undermined with cross-cuts. The surface has been pegged out so as to give an accurate map of the underground workings. Mechanical stoking is used for the power plant. Two centrifugal pumps on the 1,200-ft. level of the Farrel No. 2, the main working shaft, throw 1,000 gal. per min. for 1,200 ft., one Knowles on the 700-ft. level pumps 500 gal. per minute.

The Reins Copper Co., working the Combination mine east of the Leonard, has a shaft down 1,200 ft. and has established stations at the 800 and 1,000 and 1,200 ft. levels from which cross-cuts have been run. At the 800, a Jeanesville and a Knowles each can pump 700 gal. per min., and at the 1,000 a Jeanesville and a Cameron can handle 400 gal. Two sinking pumps in the shaft complete this installation. At present they are pumping but 200 gal. per minute.

At Centerville, north of Butte, the Raven Mining Co. opened up the Raven and Snoozer claims by means of cross-cuts on the 800, 1,200 and 1,500 ft. levels from the Buffalo shaft. But the Amalgamated Co. has recently caused them to stop work. W. D. Thornton is president and John Berkin manager. This property is west of the Mountain Con. group of the Anaconda Company.

South of the Silver Bow mine of the Amalgamated Co. the East Butte Mining Co. has consolidated a number of claims whose upper levels are now being worked by lessees. These include the Lassen, Yankee Boy, Oneida, Mary McLane, Dutton, Jackson, McDonald, Hancock and Wheeler. Shafts have been sunk to a depth of 300 ft. and cross-cuts have opened up five east-west veins. Lessees are shipping 125 tons of high-grade ore daily that runs from 8 to 12% copper, on which the company is getting a royalty of 25%. The company has put in hoists and a 16-drill compressor at the Dutton and Yankee Boy, and will sink two shafts to a depth of 1,000 ft. within the next six months. Jas. W. Neill is consulting engineer and Patrick Wall general manager.

The companies working along the east edge of the flat are the Butte & London, sinking on the Greendale placer; the Butte Copper Exploration Co., on the Six O'Clock; the Boston & Montana, on the Greenleaf; and the General Development Co., on the Altoona. The Venture Corporation of London is said to own a controlling interest in the Butte & London Copper Development Co. This company is sinking a shaft through the wash to bedrock. When a depth of 1,500 ft. is gained, a cross-cut will be run to tap veins believed to be there. Southeast of the Butte & London, the Butte Copper Exploration Co. unwatered the 400-ft. shaft at the Six O'Clock and will sink it to a depth of 1,000 ft., cross-cutting at intervals to prospect the country. South of this shaft, the Amalgamated has been sinking a shaft on the Greenleaf since last November.

The General Development Co., backed by the Lewishohns and engineered by J. Parke Channing, unwatered the Altoona shaft southeast of the Pittsmtont, preparatory to opening up the Amazon group. Options have been taken on many other claims, high-grade copper ore having been found in many places in the east belt. The Butte Copper Belt Mining Co. also is prospecting some of this ground.

Far north of any copper producers, toward the head of the Yankee Doodle gulch, the Butte & Bacorn Co. has nearly 400 acres of promising ground. Three shafts are being sunk and hoisting engines installed at the Colleen Bawn, Belinda and Calumet. Numerous veins can be traced throughout this territory. Although little copper is found on the surface, yet, following the analogy of the mines on Anaconda hill, it is argued that chalcocite will be found in depth. It is probable that the copper has been leached out in the zone of oxidation and re-precipitated on pyrite by descending solutions. If this be the case, this section should be as important a producer as the mines on the hill, for surface work has shown the veins are strong and well defined. Where the circulation has been poor, as in the 'gouge' on either wall, good copper values are found. Edward Renouard has charge of the work. The same lode is being explored by the Butte Hill Copper Mining Company.

The Butte-Montana Mining Co. is working the Alec Scott, the only claim on Anaconda hill not owned by the Amalgamated interests or those friendly to them. The shaft is down 680 ft. and sinking is to be started as soon as a new hoist and boilers can be put in. The company also owns the Little Annie claim near the Goldsmith. W. J. Dawson is superintendent. The Butte-Milwaukee Co. is sinking on the Stonewall and on the Pollock in the North Butte district. The East Butte Extension Co., the Alliance Copper Co., and the Northeast Butte Copper Co. are working in the East Butte section. The Butte & St. Louis Mining Co. is working the Kessler property in North Walkerville.

The Butte Commercial Copper Mining and Development Co., the Butte Central Copper & Smelting Co., and the North Butte Mountain Copper Co., are among the latest companies incorporated. The West Butte Mining Co. has taken over half a dozen claims under option, in addition to the purchase of the Columbia, on which the original capitalization was based. The Butte & Veronica Mining Co. owns 12 acres of ground west and south of the Belmont mine.

All of these companies, including the East Butte, have been formed within the past six months. Their formation, flotation and operation is today one of the most remarkable features of Butte. Since the wonderful showing of North Butte, public interest has been aroused in the possibilities of mining outside of the 'mile limit.' This in itself is laudable; but it is accompanied by a general dabbling in stocks. The population of Butte is becoming stock mad. Secretaries of mining companies are among the few who here violate the rules of eight-hour labor; they are feverishly at work endeavoring to write out certificates of stock fast enough to supply the public demand. This demand is universal among all classes. The bank president places a large order at the same time that his stenographer and office boy take their weekly earnings to the 'bucket shop.' The mine-owner and the mine-worker both hold stock in the same company. Many are putting their all on a margin, in the hopes of a rise. This is deplorable. Butte copper shares are surely on a rise, yet they can easily be controlled by an unscrupulous few, to the imminent danger of the small speculator. At all times and at all places among men, women and children, the one topic of conversation for the past ten months has been mining stocks. There are few school-teachers that do not own a share in at least one hole in ground. The ladies glibly discuss the strange terms of the stock-exchange over their tea-tables. Anyone having a 'tip' is sure of a welcome. The children on the streets can tell the market value of some share in which their parents are gambling. It is not my place to moralize on this condition. Some will gain and some will lose. Butte may be an exception, for she points

with pride to her past record of never having had a 'wild-cat.' The money is now going into the ground.

This stock gambling is but one of the contrasts presented by this overgrown mining camp, just waking to a realization of its size and strength. For the civic league has "shut out the tiger"; 'tin-horn' gamblers are almost the only professional men out of a job; poker is under a ban. To a visitor this seems inconsistent. Among those now most strongly opposing the existence of a "wide open town" are men who are risking everything on the rise of stocks.

As for suffering families, there are few here to be affected. Butte is a man's town, rude, strong and careless. Every day eight thousand men come up from underground and pour out through the streets into the saloons and lodging houses. Two thousand more come from the various surface workings. The rest of Butte's great population live from the wages of this basic class. Muckers get \$3.50 per day, and every other worker in ascending proportion. Men of every nation have floated to this cosmopolis; Austrians and Italians are herded in cheap tenements, Swedes and Norwegians are colonized in boarding houses, Welshmen and Cornishmen congregate clannishly, but the Irishman is generally the boss. He is a remnant of the old Marcus Daly days, big, powerful, overbearing—a driver of men. But right in his midst is growing up his master. Young men from every mining school in the land are toiling with the muckers, miners and timbermen, "getting their experience." Soon, as shift-bosses, foremen and superintendents, they will be more intelligently extracting this great amount of ore, even now aggregating 3,500 tons daily.

Because of the necessity of amusing this conglomeration, Butte is the best 'show town' of its size in the country. It patronizes them all, from the high-class opera to the low-down music hall, impartially too, for one finds the Italian car pusher at the opera, and the consulting engineer at the music hall, drinking his beer with the rest of the boys. St. Patrick's Day, Fourth of July, Labor Day, and Christmas are the great holidays, generally rendered memorable by a prize-fight, a horse-race or coursing. Big dinners and big drinks are the favorite means of entertainment. Because of the winter cold, many of the men are clad in furs, and diamonds flash from their fingers and ties more frequently than they do from the women elsewhere.

As a town Butte presents a queer jumble of unpainted shacks and magnificent steel buildings, all built helter-skelter around some tall gallows-frame or smokestack. A miner often lives within ten yards of his own little shaft, his cows and chickens running over his dump, the week's wash hung from the head-frame and fluttering in the mingled coal smoke and smelter fume. First laid out as roads, the streets are a tortuous perplexing maze, skirting waste-dumps, veering from high board fences around some shaft, and all following the rough contour of gulch and hill. Sight is often unavailing because of thick clouds of fume and fog, yet the locomotive's shriek, the engine's exhaust, the cable rattling over the sheaves, the piano's jangle, continually greet the ear, and the mingled odors of sulphur, coal, whisky, and garlic assail the nostril, each guiding one wheresoever he desires.

Night and day the streets and hills are alive with men, coming off or going on one of the three shifts. On a bright day the congestion of humanity often renders progress slow. From a distance the town is prettiest by night with the myriads of electric lights dotted over the hills, sudden brilliant glowings marking the lurid path of the molten slag from the smelters.

WITHOUT SPECULATION there is no good and original observation.

Tests for Tellurium.

In the *Monthly Journal* of the Chamber of Mines, Western Australia, Mr. H. B. Wright gives the several tests for tellurium in the presence of pyrite, he describes them thus:

1. The usual and very delicate test for the detection of tellurium occurring as a telluride, that of heating a little of the finely powdered mineral with strong sulphuric acid and securing a reddish-violet coloration of tellurium sulph-oxide, fails when applied in the presence of pyrites. This is due to the reducing action of sulphur dioxide, which is liberated when iron pyrite is heated with strong sulphuric acid.

2. The sodium-amalgam test also fails in the presence of pyrite, the sodium sulphide formed in the re-action destroying the reddish-violet coloration of tellurium sulph-oxide.

3. Oxidizing the pyrite with strong nitric acid, evaporating to dryness, boiling with caustic soda to dissolve the tellurous oxide formed, and precipitating the bases as hydrates and filtering to obtain the tellurium as sodium tellurite is also unsuccessful, as the tellurium is precipitated in combination with the iron.

4. The most reliable test for detecting even traces of tellurium in the presence of much pyrite is as follows:

Thoroughly oxidize the pyrite with strong nitric acid, evaporate to dryness, take up with strong hydrochloric acid, boil, dilute with water, and filter off the insoluble residue.

Through the filtrate made boiling, pass a rapid stream of sulphur-dioxide until the filtrate is thoroughly saturated with the gas; the tellurium and any gold will be precipitated in the metallic state. Filter off the tellurium (and any gold), wash with water until free from the salts of the filtrate. Wash the tellurium from the filter-paper into a small evaporating basin, evaporate just to dryness, and then add strong sulphuric acid and warm gradually; should tellurium be present, the violet-red coloration will rapidly develop.

This test, though somewhat lengthy, more than repays the operator for the trouble occasioned. It entirely removes any doubts which 1, 2 and 3 are almost certain to produce.

THE Greenwich observatory is seriously affected by the new main power-station of the London County Council electric railway system. The power-station is about half a mile distant from the observatory and almost due north. It is to have an ultimate capacity of about 50,000 h.p., but only part of the machinery is installed and not more than 3,000 h.p. is generated at the maximum; vertical engines are used. The vibration produced by the engine is noticed strongly at the observatory. The instrument most particularly affected up to the present is a portable transit used for longitude work. Trouble is also caused by the smoke and hot gases issuing from the stacks of the power-station, which give rise to disturbing refraction effects. An investigation is to be made by the British Admiralty and the London County Council to determine the nature and degree of the disturbance and how it may be remedied.

AS NO MAN fording a stream can dip his foot twice into the same water, so no man can, with exactness, affirm of anything in the sensible world that it is. As he utters the words, nay, as he thinks them, the predicate ceases to be applicable; the present has become the past; the 'is' should be 'was.' And the more we learn of the nature of things, the more evident it is that what we call rest is unperceived activity; that seeming peace is silent but strenuous battle.

A Quick Vertical-Shaft Survey.

Written for the MINING AND SCIENTIFIC PRESS
By W. E. DOWNS.

This article deals with the method I have used for 15 years in making quick and accurate surveys of various vertical shafts in Amador and other counties along the Mother Lode of California.

The essential features of the method are the use of heavy plummet lines and 'bobs,' hanging free, while being set, but securely fastened while observations are being taken. I can best illustrate the operation of this method by citing an actual case, that of my survey of the Oneida vertical shaft in six hours on July 6, 1902. This main working shaft of the mine was sunk 1,000 ft. east of the outcrop and intersected the vein, which dips to the east, 1,900 ft. below the surface. The vein was then being worked through six levels at 1,200, 1,500, 1,700, 1,800, 1,900, and 2,000 ft., vertically below the collar of the shaft.

The adverse conditions under which this survey was made were: A very wet shaft, through which water literally poured in torrents; a shaft distorted and narrowed by swelling ground at the 1,800-ft. level, and a shaft with an excessive number of working levels into each of which the survey had to be tied from one hanging of the plumb-bobs and as quickly as was consistent with good work, so as to interfere as little as possible with the regular operation of the mine and the use of the shaft.

To overcome these adverse conditions, two large-sized (No. 12 gauge), soft-drawn iron wires were suspended in the centre compartment of the shaft, with a 125-lb. plumb-bob attached to each, less than one foot below the 2,000-ft. level, the wires sliding from the surface with the bobs attached, through notches in plank. At the 2,000-ft. station, opposite each wire, a template, made from a piece of candle-box, was so placed and fastened with a wire-nail at one end that the free end could be swung or moved to or from the wire in a horizontal direction practically in line with both wires. By the interposition of a small piece of wood laid loosely upon each template, with its end projecting over, and in contact with, the advancing side of the oscillating wire, the latter was brought to rest after the retardation of a very few oscillations. The position of rest was then carefully marked on the template. As the oscillations diminished, the template was brought closer to the wire until finally, when the latter was at rest, the template was brought in contact with it and nailed in place. The wire was then fastened to the template from underneath, in the position of permanent rest.

Seven settings with a transit were made, one at each station and one at the collar of the shaft—all in the same vertical plane. In each instance the instrument was set, by the 'cut and try' method, as near the nearest wire as the minimum focal distance (about six feet) of the telescope would permit, with a lighted candle in range beyond the farther wire. When in this position, the telescope may be focused on either wire at will without any interference from the other wire and accurately adjusted to the exact plane of both; this was done in each instance. The slightest sidewise tremor of either wire, which neither lasted long nor caused serious delay, was readily detected. From each setting wire-nails were accurately centred on line and driven into solidly placed track-ties, plugs, timbers, or planks, and steel-tape measurements to the nearest hundredth of a foot made to locate them with reference to the wires—all in the same vertical plane. Subsequently, from these nails, courses were extended by deflection throughout each level and to the previously established surface boundaries and all

necessary measurements made, whereby the position of each point, or instrument-station, in the whole system was determined with reference to every other point. From these data the entire system was accurately mapped and the field-notes tabulated for future reference, so that the survey could be extended and mapped as development work progressed.

In this survey the horizontal distances between plummet-wire centres were respectively: 2.43 ft. at the collar, 2.44 ft. at the 1,200-ft. level, and 2.45 ft. at the 2,000-ft. level. The divergence of these wires downward is due to but one cause, which is purely gravitational. The mass of rock that would have to be in place between the wires to have them hang parallel or more theoretically to converge toward the centre of the earth, was absent, and of course the wires came to rest, diverging slightly downward. Drafts and falling water in the shaft do not have any effect upon the sum total of this divergence, although they do create tremors and also operate to check the same.

In contrast with the hard-drawn piano-wire method of hanging bobs of necessarily light weight in molasses or some other viscous liquid, this method has no equal; it is quick and reliable, it has proved so to my entire satisfaction in numerous instances where I have made surveys for underground connections.

A plummet line of large-sized soft-drawn wire has two decided advantages over one of small-sized hard-drawn wire; they are as follows:

First. In the process of hanging wire, all kinks and internal strains are absolutely removed by stretching, leaving the wire perfectly straight, a condition impossible with hard-drawn wire wherein kinks and strains are left, subjecting the wire to local wobbles nearly as great as the diameter of the wire itself.

Second. As external disturbances, due to drafts and falling water, are of a magnitude proportionate to the exposed surface of the wire, and as the strength of a wire is proportional to the square of its circumference and therefore to the square of its exposed surface, it is plain, although a hard-drawn wire is stronger per unit of cross-sectional area than a soft-drawn wire, that if the difference in size is great enough, a large soft-drawn wire is better adapted to withstand said disturbances than a small hard-drawn wire. The so-called advantage of being able to bisect a small-sized wire with the vertical cross-hair of the instrument better than a large-sized wire is in practice a myth, particularly when contrasted with our first advantage.

The bobs must be symmetrically made, preferably of solid shafting accurately turned in a lathe and centred with an eye at one end to receive the plummet wire which must be a continuation when suspended of the axis of the bob, so that there will be no local wobbles in the wire when the bob revolves, which it will do to a small extent.

It has been claimed that the gold-bearing veins of the southern Black Hills of South Dakota are unaccompanied by intrusive rocks of any kind—that no igneous rocks are found in the Black Hills south of the Lawrence county line. This is an error, for at and near Rochford, on Castle creek, and throughout the region of gold mines as far south as Spring creek, are found numerous dikes of diorite and diabase, probably all of Algonkian time, which merely shows that ore-forming processes were similar in pre-Cambrian time to those of the later periods, when the intrusives were generally more acid in character. In southern Pennington county and in Custer county are found many intrusive granite dikes (pegmatite), some of which are associated with gold-bearing quartz lenses and occasionally the pegmatite is itself gold bearing.

Haulage in Iron Mines of Alabama.

Written for the MINING AND SCIENTIFIC PRESS
By W. R. CRANE.

Of the many improvements inaugurated in the hard iron-ore mines of the Birmingham district, none are of more importance, considered from the standpoint of economy, than those that have to do with haulage and handling of the ore, both on the surface and underground. The change made in methods of mining, from stripping to underground working, necessitated a radical departure; with an increase in depth still further changes have been made, so that at the present time it would seem that a practicable economic limit has been reached.

During the period of open-cut work the ore was transferred by systems of rope-haulage from the outcrop at the top of the mountain (Red) to the level ground at its foot. Occasionally it was shot down in chutes. Later, lines of railroad were laid along the flanks of the mountains at such levels as to permit the ore to be drawn directly from the tipples, which are provided with storage-bins; and this is the system largely employed at the present time. (See Fig. 1.) The tipples are extensions of the main haulage-ways or slopes leading from the underground workings. Often, two or more slopes were connected by surface lines of haulage, either extending along the line of the stripping or on the waste-banks; usually one engine served a double purpose—that is, it furnished motive-power for the horizontal hauls and for the planes in transferring from one level to another to accommodate loading into the railroad cars.

As stated, mining was formerly done by open-cut, the work being done largely by hand; and, although such work is still carried on at favorable points, underground work is now almost universal. The room-and-pillar system is employed; this is done in two operations—namely, forming pillars on the advance and robbing them when retreating. The mines are opened by inclined shafts, but as the inclination is usually moderate (about 20 deg.), they are more appropriately called slope-mines. The pitch of the ore-stratum is variable in both horizontal and vertical directions, by reason of change in direction of strike. Usually at a point from 100 to 150 ft. from the outcrop, the pitch changes abruptly, becoming much steeper. (See Fig. 2.) These sudden changes in grade are called 'nuckles' and necessitate slower haulage.

The handling of the ore, delivered to the slopes in the pit-cars, is accomplished either by car or skip—preferably the latter. Cars were employed during the early period of underground mining and they are still in use in a few

mines, but skip-haulage has been found to afford increased capacity at lower cost, it requires fewer attendants (ratio, 1 to 8), and it simplifies mining and management. The choice of system determines the method of mine development.

The development work consists in driving passages called 'headings' from either side of the main slopes. These headings must be given proper grade for haulage, usually 3 to 4% in favor of the loaded cars. To maintain the grade, and still keep within the ore, it is often necessary to make the heading irregular. The angles of intersection of headings and slopes are often acute, owing to the effort made to maintain the desired grade, which may seriously affect the haulage of trains of cars from headings to slopes.

When car-haulage is employed, on the slopes, it is found advantageous to off-set or 'stagger' the openings of the headings on the slopes, in order that switches on opposite sides may not come at the same points on the slope-track, thus simplifying the operation of switching as well as

the laying of the switches. The off-sets range from 15 to 25 ft., but vary with the height of the lift. Further, with car-haulage the headings connect with the slopes by means of upward curved passages, as in slope-haulage in coal mines, while with skip-haulage there is no connecting tracks between headings and

Fig. 1. Tipple, With Skip in Act of Dumping.

slopes—the headings being driven from the slopes at right-angles. Little or no off-setting is done with skip-haulage, the headings being practically opposite each other. When skips are employed it is necessary to depress the slope-tracks in order that the skips may receive their loads from the pit-cars operating in the headings, which necessitates the running of the slopes in the underlying formations. If the lower bench of the ore-bed is soft, only the upper portion will be worked, the slopes being driven the full height of the stratum. A change in the system of haulage requires a lifting of the bottom of the slope, thus materially increasing its height—the headings remaining unchanged, save from the arrangement of the tracks. The depression of the slope-track for skip-haulage is 8 ft. 6 in. below the heading-track.

The skips have capacities ranging from 8 to 15 tons; they are made of steel, and are open at both top and front. The fore-end is, however, provided with a gate, G, which is kept closed during haulage by the bail acting on two arched ribs, E (Fig. 3), and is in turn freed at the instant of dumping by the raising of the bail. The partings in the headings, adjacent to the slopes, are usually provided with two tracks to accommodate empty and loaded cars, thus facilitating handling.

With car-haulage, trains of five to eight cars are hauled from the partings, where they are made up, onto the slope, thence to the surface, and are returned in like manner, the switches being set to turn the cars into a given heading. The acute angles and consequent short curves, often formed by headings with slopes, renders the transference of trains of cars, either way, extremely difficult. Deflecting sheaves, employed on the upper ribs of the headings, facilitate the passing of the cars, but do not by any means remedy the evil.

Formerly wooden cars, iron-bound, were employed almost exclusively both for mine and slope-haulage, while at the present time metal cars are rapidly replacing the wooden forms. These cars have a capacity of about two tons and operate on 36 to 42 in. gauges—the former for wooden, the latter for metal cars.

In hard-ore mining the pit-cars are filled by shovel,

being uncoupled and handled separately. Cradle-dumping of whole trains of cars, without breaking connections with the winding-rope, is occasionally employed.

When skip-haulage is the practice, the tipples are built close to the mouth of the slope and are given the inclination of the upper portion of the slope. Above the main tippie-track is built an elevated track, with a gauge of 70 in., or 10 in. greater than the slope or tippie-track below. This track stands 4½ to 5 ft. above the floor of the tippie, is strongly built and braced, and is connected with the tippie at the lower end by a section of track, *D* (Fig. 1), of considerably steeper grade. Surmounting the elevated track in turn is a wheel-guard, *L*, which stands above the rail, a distance slightly greater than the diameter of the rear wheels of the skip that run upon the track. The skips are provided with 24-in. wheels, which run upon the 60-in. slope-track. The rear wheels are double—t hat

Scale 1 : 1200

while standing on the heading tracks at the foot or bottom of the lifts, while branch tracks are often found to be necessary when soft ore is mined, and especially when the working face has advanced to the top of the lift. With moderate pitches these branch tracks can be run for at least one-half the height of the lift. The reason for the difference in arrangement of tracks in headings and rooms is due to the marked difference in character of ore and consequent variations in angles of repose—the hard ore breaks coarse and readily finds its way to the heading tracks, while the soft ore breaks fine and is moved with difficulty, especially on slight inclinations. The gauge of the skip-track is 60 in., weights of rails for cars and skips are 30 and 60 lb. per yard.

Prior to the employment of skip-haulage, rather elaborate systems of handling and emptying cars were employed. Switch-backs connecting the mine slopes with the tipples were the rule. Double-engine plane haulage was also common—that is, hauling up the mine-slope to the surface, then transferring the cars down the face of the mountain to the railroad-track, which arrangement often resulted in a combination of engine and gravity planes. As a usual thing, the surface ends of the haulage systems terminate on a tippie upon which the cars are run and dumped. Hand-dumping is in vogue, the cars

is, they have small side or hub-wheels of 12-in. diam., mounted upon the same axle as the regular wheels, which give them a double tread, so that when the skip reaches the tippie the fore-wheels maintain their position upon the main track, while the hub-wheels strike the inclined section of track, *D*, leading to the elevated track and mount upon it, thus securely and readily changing or reversing the inclination of the bottom of the skip. The inclination thus given, or the dumping-pitch, is about 40 deg. The gate at the front of the skip, which up to this time has been held tightly closed by the cross-bar of the bail, is freed by the change in position of the body of the skip and swings or is pushed open by the discharge of the skip's contents—the discharged material entering the ore-bin below.

To permit dumping at several points, two at least, as in the ore-bin, *A*, and the waste-chute, *B*, a change in inclination of the skip must be effected at a point below that necessary for dumping ore, which in this particular case is directly above the waste-chute, *B*. A second section of track, *C*, is then provided, which also connects the main and elevated tracks, as previously described. To permit the use of the track, *D*, a break is made in the elevated track just above and back of the point where the two join, also in the first inclined section or approach,

C, to the elevated track, both of which are provided with portions of track, *E* and *F*, hinged so that they can be raised, thus allowing the hub-wheels to pass *C*, or lowered, throwing the travel on *C*. It is evident that by means of the approaches, *C* and *D*, and the hinged portions of track, *E* and *F*, which are in reality switches, the contents of a skip can be readily discharged either into the ore-bin or waste-chute, as desired.

When the slope is being sunk simultaneously with the work of extraction of ore, the waste obtained from the sinking operations is handled in a second or trail skip, which is connected with the main skip through some 30 ft. of wire rope, and is thus lowered to the bottom of the slope and hauled to the surface with its load, both acting together. By a careful manipulation of the switches, *E* and *F*, the two skips can be made to discharge their contents into their respective places with little loss of time.

Change in method of handling ore, both below and above ground has been largely instrumental in bringing about a radical improvement in the power equipment. Centralization of power plants (air, steam, and electric) has resulted in increased output with a material reduction in cost. Air and steam, especially the former, are often piped from a central station for considerable distances to adjacent mines. Usually, however, each mine has its own steam-plant for furnishing power for winding and reduction purposes. Second-motion hoists equipped with 10 to 12-ft. drums, with post-brakes, and having a capacity of 50 to 100 tons per hour are in common use. Steel cables $1\frac{1}{2}$ and $1\frac{3}{4}$ in. diam. are used for slope winding.

Owing to the steepness of the mountain upon which the ore outcrops, it is often necessary for the tippie and hoist to be far apart, thus necessitating intermediate supports to reduce swaying of the winding ropes. The tipples proper are trestle constructions, the main floors of which have the same inclination as the slopes. They are made of bents strongly braced by levelers and diagonals; they contain the large ore-bins, which are really only feed-hoppers for the crushers situated below, and waste-chutes (see Fig. 1). Directly below the ore-bin is a large spindle crusher, which is supported by the same trestle-work construction that contains and supports the bin, waste-chute and dumping-track. Gates improved No. 8 crushers are largely used; they are operated single or double-eye, that is, with one-half or the whole of the hopper-space open for the passage of ore, according to the capacity desired. They require about 30 h.p. to drive them, and reduce mine-run ore to $2\frac{1}{2}$ inches.

Although the occurrence of the ore strata and the methods employed do not present any serious obstacles to the handling and haulage of the mine product, yet the extent of the operations, with respect to number of mines owned and operated by a single company, necessitates a large and efficient working force, well organized. That the work is carried on smoothly speaks well for the management.*

THE ORE of Rio Tinto, Spain, contains about three per cent copper disseminated in the form of copper sulphide (chalcocite), in massive iron pyrite, presumably by secondary enrichment. Great heaps of the mineral, as it comes from the mine, are allowed to oxidize under the influences of the weather, the copper sulphate thus formed being subsequently washed out by water and precipitated on iron. The success of this method of treatment is due to the fact that the copper occurs as glance, and not as chalcopyrite, which oxidizes very slowly in the atmosphere.

Canada's Nickel Deposits.

Written for the MINING AND SCIENTIFIC PRESS
By J. A. MACDONALD.

The report which Dr. Haanel, Superintendent of Mines for the Dominion Government, has prepared for the Minister of the Interior regarding the experiments in electric smelting recently conducted at Sault Ste. Marie is of exceptional interest to the Canadian mining industries. If what Dr. Haanel says is true, that the process of electric smelting, invented by Dr. Heroult, is a commercial success, there is no doubt that mining will be given a new impetus. Particularly will this be so at Sault Ste. Marie.

In the Sudbury district of Ontario there exists the greatest nickel mines in the world. The average Canadian, Englishman and American possibly is not aware that Canada is the biggest producer of nickel ore. According to a statement from the Geological Survey, the value of the nickel output in Canada in 1905 was \$7,550,526, or a little over 11% of the total mineral production of the country. There was an increase of \$3,331,373 as compared with the previous years. Out of the total production of 18,876,315 lb. in 1905, 17,218,059 lb. were exported to the United States and Great Britain.

The story of nickel mining in the Sudbury district is interesting, much more so than the ordinary person would suppose. It was in 1846 that nickel was first discovered at the Wallace mine. The interest aroused at the time soon died away, and it was not until ten years later that attention was again called to it by the discovery of large quantities of nickel and copper six miles north of White Fish lake, and near the present Creighton mine, probably the largest deposit of nickeliferous pyrrhotite ever discovered. This discovery also aroused but little interest, and not until the construction of the Canadian Pacific Railway did operations begin in earnest. Then inside of ten years, all the mines which are now in operation were located. In 1886 the Canadian Copper Company was formed with a subscribed and paid-up capital of \$2,000,000, afterward increased to \$2,500,000, to work a number of the larger mines. This was the first combination of capital and skill which seriously undertook mining in the Sudbury district. The first blast-furnace was blown in during December, 1888. A second one was installed in the following year. During these years numerous mines were located and operations begun, only to be abandoned a short while later for want of capital. The famous Creighton mine was opened in July, 1900. It is undoubtedly the largest in the district, and from the very beginning of operations has produced large quantities of almost pure sulphide, with little or no rocky admixture. The Creighton mine is at present the main source of supply, its equipment permitting a production of between 500 and 600 tons of ore per day.

Since the organization of the Canadian Copper Company a dozen other companies have been organized, but most of them have faded away, in the majority of cases because of a lack or waste of capital, owing to absence of business and judgment, and the need of technical knowledge of the difficulties to be encountered in both the mining and smelting departments. In many cases all the available capital was utilized in costly experiments to discover new methods of smelting or refining. The history of the development of mining in the Sudbury district includes a long list of brilliant successes, but the failures bring into strong relief the gallant and successful struggle of the only company that has been able until recently to surmount the numerous difficulties. The crisis, however, is now past and the industry has been established on a firm basis.

*For the outline showing method of handling ore in the mine, the writer is indebted to the Tennessee Coal, Iron & Railroad Company.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

MEANS FOR DISTRIBUTING MINE RESIDUES.

—No. 825,292; August L. E. Bergert, Johannesburg, Transvaal.

In apparatus of the nature specified, a conveyor belt and a boom supporting said belt, said boom being capable of swinging in a plane the angle of which to the horizontal is constant and of oscillating about its longitudinal axis.

APPARATUS FOR TREATING SLIMES.—No.

826,390; Carlos W. Van Law, Guanajuata, Mexico.

In an apparatus of the class described, the combination of a filtering-tank and a slimes-pressure tank, means for forcing slimes from the pressure-tank to the filtering-tank and through the filter by air at pressure above normal, means for equalizing the pressure in the tanks, and means for subjecting the interior of the filter to air at pressure above normal.

PROCESS OF TREATING ACID LEACHING SOLUTIONS.—No. 825,302; Percy F. Cowing, New York.

A process of treating pyrite containing iron in addition to metals incapable of remaining in a mineral-acid solution in the presence of hydrogen sulphide, which consists in fusing said pyrite in the presence of metallic iron and in the

absence of air or oxygen, and finally subjecting the product produced by such fusion to the action of an acid-leaching solution containing a metal whose sulphide is insoluble in the acid in the presence of hydrogen sulphide, whereby hydrogen sulphide is evolved, the iron goes into solution, and the other metals in the product and leaching solution are precipitated or left out of solution.

TILTING ORE-ROASTING FURNACE.—No. 825,446; Thomas Edwards, Ballarat, Victoria, Australia.

An ore-roasting furnace, having a pair of longitudinal chambers, one above the other, and a connection between them, the upper chamber being for ore, a plurality of lines of rabbles in the upper chamber having the intersecting hearth areas, the said lower chamber having the longitudinally extending partition therein and dampers controlling the fume outlets of the said chambers.

METHOD OF TREATING COPPER AND NICKEL MATTE.—No. 826,099; John A. Gilman, West Fairlee, Vermont.

Process for treating copper and nickel mattes which consists in finely subdividing the matte while in a molten state, projecting the particles in a stream downwardly by gravity, and blowing the stream laterally with a current of air to remove the sulphur of the particles.

SAFETY GEAR FOR MINE SKIPS AND CAGES.—No. 825,353; Bruno Schlesinger and Edwin G. Weldon, Johannesburg, Transvaal.

In safety gear for mine skips, cages and the like, in combination, a cage or skip, an oscillating cylinder carried by said cage or skip, a piston arranged in said cylinder, a piston rod attached to the piston and means which operate when the support for the load is removed to bring said piston rod into engagement with teeth, projections or recesses in the guide-rails or runners of the shaft, well or the like.

The Nissen Stamp.

Written for the MINING AND SCIENTIFIC PRESS
By PETER N. NISSEN.

The largest gravity stamp-mill in the world is to be built at Garfield, in Utah, by the Boston Consolidated Mining Co., for the crushing and concentration of ore from its great low-grade copper mines at Bingham.

After severe tests, conducted for a period of over six months, by Mr. A. J. Bettles, the contract was awarded to Messrs. Fairbanks, Morse & Co. for the installation of 360 Nissen independent stamps, with a provision in the contract that a further number of 360 stamps shall be added after completion of the first installation. By the tests it was conclusively proved that on the ore to be treated, which is a

The Nissen Stamp.

quartzite of medium hardness, the Nissen stamp has a capacity of 10.75 tons per 24 hr. through a 28-mesh screen. The daily capacity of the finished plant may therefore be estimated at 4,000 tons, which will be much in excess of the capacity of any existing stamp-mill. The gravity tests were conducted with the greatest fairness. Complete mills, including besides the Nissen stamp, ordinary five-stamp batteries, rolls, and circular mills of various kinds, were run on the same ore, so that there could be no error in comparing results under different conditions. Mr. Bettles's problem was to reduce to 28-mesh ores averaging 1.5% copper and to get the best possible product for concentration at the least possible cost. Without wishing to go into comparisons, I may say that the fact, as demonstrated during the test, that the Nissen stamp made 10% less slime than any other competing mill, had much weight in the final choice.

In the Nissen stamp there have been retained the well-tried principles of the gravity stamp, the new features being particularly in the use of a circular independent mortar to increase the discharge of the stamp, thereby increasing its capacity as much as 10% in proportion to the horsepower required for its operation. The cross-section of our mortar is similar to that of the ordinary mortar, and the screen is relatively the same distance from the stamp in its horizontal points. Owing to the fact that the area is so great and also that the screen is in a position to receive the impact of the pulp against it at right angles always, a uniform crushing is accomplished without excess wear on the screens. The mortar is effectually protected from wear by a lining that is cast in one piece and held in such a manner that it causes no trouble by working loose. The feeder is of the improved Challenge type, designed to work easily, so that constant attention is not required to keep the nuts and pins from becoming loose; also by feeding the stamp independently, steady and regular operation is insured, so that the shoe and die wear much more evenly than in other types of mortars, and allow closer feed. As to material used, the cam-shafts and stems are of hammered steel, the shoes and dies are of a

special mixture or hard metal; the cams and tappets are of cast steel. A cam-shaft bearing is placed on each side of every cam, which goes far to do away with the danger of breakage.

Briefly, the advantages of this type of stamp lie in the ready and positive discharge—owing to the increased screen surface, every part of which is at right angles to the splash; in the avoidance of slime, because, for the reasons above cited, there is less re-grinding, and economy in power—chiefly for the same reasons. The effort has been made to relieve the mill promptly and as thoroughly as possible of pulp fine enough to pass the screen; and although in the course of ten years' experiment certain minor advantages have been developed, the feature mentioned is the main issue, and to it the success of this type of mill is due.

In operation, the Nissen stamp-mill is similar to the ordinary five-stamp battery, save that each stamp is independent and larger, weighing 1,500 lb. and the shoe is of 10-in. diameter; there is an independent mortar for each stamp, and the screens are semi-circular for each unit. From one to six stamps may be operated on the same cam-shaft, and any stamp in the battery may be hung up for any purpose without interfering with the continued operation of the other stamps.

In 1905, Fairbanks, Morse & Co. entered into an arrangement whereby they became the sole manufacturers and selling agents, controlling our patents. They have sold several plants of good capacity since the first of the year, and are now about to install plants in Idaho, Oregon, and Montana, besides several in Mexico, the Southwest and the great plant at Garfield.

Bulletin No. 291, of the United States Geological Survey, A Gazetteer of Colorado, and the Redding, Cal., quadrangle Folio 138 of the Geologic Atlas of the United States.

The Twenty-Fourth Annual Coal Report of the Illinois Bureau of Labor Statistics for 1905. Including the Seventh Annual Report of the Illinois free-employment offices.

The production of quartz and feldspar, slate, phosphate rock, magnesite, carbon dioxide and of salt, in the United States during the year 1905, being advance sheets of the 'United States Mineral Resources,' by the Geological Survey.

The Denver, Northwestern & Pacific railway has issued a pamphlet descriptive of the oilfields through which that new road passes, which cannot fail to interest oilmen. It describes the geology of the region and gives results obtained at several wells together with analysis of the oil.

Commercial Paragraphs.

GEORGE W. PRICE & Co. is now at the old place, 25-31 Jessie St., San Francisco, with a large shop and good facilities for handling pumps, gasoline engines and fittings.

THE PELTON WATER WHEEL Co. is temporarily at 517 Market St., San Francisco, but expects to be permanently situated in the Monadnock Bldg., San Francisco, by August 15.

THE BUFFALO FORGE Co., of Buffalo, New York, has installed a large irrigation plant on the McBryde plantation, on the island of Kauai, one of the Hawaiian group, where the plant is in successful operation.

ALLIS-CHALMERS Co., of Milwaukee, reports the following recent sales: Boston & Montana C. & S. M. Co., two 32 by 72 in. hoisting engines; Ansonia Brass & Copper Co., Ansonia, Conn., 19 and 38 in. by 42 in. Reynolds combined horizontal and vertical engine; Bullychoop Gold Mining Co., Trinity county, Cal., complete hydraulic electric transmission and mining equipment, including 20-stamp mill, motors, a 450 kw. generator, direct connected to water wheels, and a transmission line 3½ miles long; Camp Bird, Ltd., Ouray, Colo., thirty 6-ft. Frue vaning machines, stamp-mill machinery, etc. Wheeling Milling Co., Mine La Motte Station, Mo., 25 ft. Hancock jig. St. Joseph Lead Co., Bonne Terre, Mo., standard 25 ft. Hancock jig.

Editorial.

THERE IS to be an International Mining Exposition at New York in 1908. Already a company has been organized at 564 Monadnock Bdg., Chicago, to further the interests involved. It is the intention to have a grand exhibit of mining machinery and to utilize the occasion for a meeting between all those who are connected with the mining industry of this and other countries.

SPECULATIONS concerning the locality of the next mining excitement in Colorado lately occupied the attention of our friends at Denver, and now we read that Mr. S. F. Emmons has suggested the White River plateau and the North Park, on the western slope of the Front range. Why not? This is an area of granite traversed by late eruptives and suggests geological conditions known to be favorable elsewhere, as at Butte.

WE PUBLISH a description of a smelter employing the Pöhle-Croasdale process, which has been undergoing trial for several years, with varying results. In brief, this process consists in crushing ore to 20 mesh by methods commonly employed in dry-crushing plants, mixing the crushed ore intimately with salt, and subjecting it to a chloridizing roast in an oxidizing atmosphere of 1,000° C. The volatilized metals—gold, silver, copper, and lead—are cooled in sheet-metal flues and the condensed fume is caught in a bag-house and subjected to further treatment for the recovery of the metals named. The metallurgical world will wait with interest to learn how successful the process proves in its commercial application.

THAT STRIKING PERSONALITY who combines the attributes of St. George and St. Vitus has thrown his spell over the country and asks everyone to endorse the funetic methods of Brander Mathuse and Andru Carnaygy. It revives memories for the 'Bad Boy's Diary' and of the sad efforts for which we were punished in early youth. The President's notions on phonetic spelling are interesting, everything he does is calculated to add to the gaiety of nations, but he takes himself too seriously sometimes, as in this matter of making a violent change in our orthography. Changes must come, but by evolution, not revolution; they will come in due course of literary development, not by the ukase of any individual, however distinguished. Language is only mutilated by such surgical operations which, after all, are not final, although "perfectly successful" from the perpetrator's point of view. The letters of the English language, unlike the Latin, have no fixed sound. Phonetic to one is funetic to another.

THE LADIES of Nevada do credit to the sagebrush State. We referred lately to the lady prospector, but we find that she is not singular, but plural. There are several of

them. It is announced in a special dispatch that another lady has been finding gold ore; this one is an expert, for she graduated from a miners' boarding house. Her vigor does credit to the cooking, for on May 23 she staked claims covering altogether a thousand acres, and thereby located an old lake, the dry bed of which consisted of gold-bearing sand. Not to be outdone, two other ladies fluttered location notices over the desert until they had 10,000 acres to their credit. They do things on a large scale in Nevada, where the horizon is so far away and the distance so magnificent.

DURING THE past week a number of Italian and Slav miners went on strike at the Kennedy mine, in Amador county, California, in order to compel the management to use safety clutches on the skips. A minority of the men refused to join the foreigners in their protest, not for lack of sympathy in the purpose of the strike, but because they could not endorse the action of men who did not belong to their union—the action was 'irregular' because it had not been authorized by the union. It appears that there is a law requiring the use of safety clutches, but there is no specific penalty to compel its enforcement, so that a company is only placed on the defensive should an accident occur and is then liable for damages. But there is a touch of humor in the other feature of the incident, namely, that a protest looking to safety of life is to go unhonored unless it be endorsed by the union.

Black Sand.

The daily newspapers have published several sensational accounts concerning thousands of acres of placer ground in different parts of the country which have been rendered of phenomenal value by reason of the alleged discovery of Dr. David T. Day, that the gravel contains large amounts of gold. It is said that samples sent to him at Washington or Portland have assayed thousands of dollars per ton, and so forth. Now, while we would not belittle any effort of the Geological Survey to aid the miners in making the most of our mineral resources, we are beginning to believe that Dr. Day's researches into black sand are affording more ammunition to irresponsible promoters and to a sensational press than they are actually improving the treatment of a material, the existence of which was known long before the much-advertised experiments were made. However well-intentioned, this work of one of the most active officers of the Survey is being ridiculed, not undeservedly. Here is a telegram from Cheyenne saying that his assay "shows that the dirt runs \$7,800 to a ton in gold, 30 per cent magnetic iron, 54 per cent hematite, making these claims the richest placers in the world." At the same time we read in one of the leading papers of Australia that "Dr. David T. Day, an American Government expert, has created a new industry in the northwest of the United States. After months of patient investigation, he has proved that the common black sands of the Pacific coast are rich in useful minerals, and that good steel can be made from this sand." This is the sort of stuff that is appearing periodically; it puts the Survey in an absurd light. Not long ago some one discovered that

clay contains aluminum and then proceeded to form a company to smelt that metal from a common mineral; indeed, Dr. Day's black sand reminds one of the story of old Governor Gilpin, of Colorado, who took Professor N. P. Hill into the San Luis valley and there expatiated to him on its possibilities as a great wine-producing region, ending up with an index finger that pointed to the glistening quartz sand at the foot of the Sangre de Cristo range; "And there, Professor, is the silica from which the bottles will be made."

A Few Inaccuracies.

The 'market letters' of stockbrokers often belong to the humorous part of current literature; they illustrate what is termed the pathetic fallacy, in its most aggravated form. Here is a sentence from the epistle of a man at St. Louis. "The fissure is 150 ft. wide, and we see no reason on earth, with the rapidly widening orebody as shown by this winze, why the ore should not become as wide in depth. There is nothing in Nature to prevent it and it is good sound reasoning to expect it. These orebodies were formed by the mineral-bearing solutions coming from depth, and isn't it reasonable to assume that the nearer you get to the source the greater will be the width in orebodies of this character. We believe we have a deep mine because it is a fissure vein. It is an orebody formed in the fissure of the earth's surface. Deep mines are what pay. Look at that great mine in Cornwall, England, 9,000 ft. deep, mining the ore from under the sea and a dividend payer for four hundred years." Here is our old friend the 'fissure vein' masquerading as an assured source of wealth and here is geology in the guise of blatherumskite. It is not too much to say that every statement in this extract is untrue. Mineral solutions do, for the most part, ascend from below; nevertheless, it is not the mineral solution, but the precipitation in concentrated form of the metals that it carries, which forms the orebody valuable to man. Mineral solutions come from the deep, true enough, but their work of deposition is done chiefly in the approach to surface, at least much nearer to grass-roots than to the centre of the earth. If lodes did become richer in depth we should see shafts sunk right down to the heart of creation, instead of fooling on top. Yes, you can have a deep mine if you follow a fissure vein, but you do not necessarily have a rich one either because it is deep or on a 'true fissure.' Some deep mines pay handsomely, but they are less numerous than the shallow ones that also pay satisfactorily. There is no mine in Cornwall, or anywhere else, that is 9,000 ft. deep; the deepest is the Tamarack No. 3 shaft in Michigan, which has been sunk to 5,128 ft. The longest incline-shaft is No. 4 Calumet, of the Calumet & Hecla, which is 8,100 ft. long and nearly 5,000 ft. deep. The tin mine under the sea is Botallack, now idle for many years, because the lode became poor. The deepest mine in Cornwall is Dolcoath, where work is proceeding at 3,000 ft. As shareholders unfortunately read the literature of the bucket-shop more than that of the technical periodical, we hope the gentleman at St. Louis will be more careful next time.

By the Way.

IN a recent address before the American Association for the Advancement of Science, Mr. Wm. H. Burr, professor of civil engineering in Columbia University, described the work on the Panama canal. As reported in *Science*, he said:

The length of the Panama canal is about 45 miles between 40-ft. contours at low water at its termini, but the length between shore lines will be not more than 42 miles.

The topography of the isthmus at the Panama crossing is well adapted to the construction of this ship canal, the original summit of the divide on the line of the canal being but about 330 ft. above sea-level. This has now been reduced to about 170 ft. above mean sea-level by the French excavation at Culebra. About one-half of the length of the canal lies along low marshy ground on either side of the isthmus, making two natural sea-level sections, one about eighteen miles long on the northerly side of the isthmus, and the other about seven miles long on the southerly side; that on the northerly side running for the greater part of its length generally along the course of the Chagres river. This river has been one of the main features in the consideration of the canal work since the beginning of operations by the old Panama Canal Co. in 1881. It is not a large river, as it has not more than about 800 square miles of watershed above Bohio, where in its flow toward the sea it leaves the rising ground and enters what may be termed the coastal plain, through which it meanders along a sinuous course to the ocean. It has even changed its course in the past at various locations in this marshy ground.

That portion of the canal route lying in the higher ground of the divide is but about 24 miles long, and but little more than three-quarters of a mile of it had an original surface elevation exceeding 200 ft. The surface material is largely clay of ordinary character, slippery and easily moved when wet, but holding well in place when protected from the entrance of water. Below this covering of clay lies material of irregular character, as the entire isthmus is of volcanic origin. In the continental divide, at a depth varying from 20 to 40 or 50 ft. below the surface, an indurated clay, classed for purposes of excavation as soft rock, is found. This material gives place irregularly to hard rock at greater depths. Much of the rock of the isthmus is soft, although there is hard basalt in a number of places and, in one locality on the Panama slope of the divide, columnar basalt is found.

The work performed by the old and new Panama canal companies amounted in the aggregate to not far from eighty million cubic yards of all classes of excavation, of which possibly forty million cubic yards at most will be found available for the American construction of the canal, whether a lock plan or a sea-level plan be adopted. This work extends practically over the entire canal route, with the exception of the approach channels in the two terminal harbors, and it is nearly continuous. Over considerable stretches of the higher ground it is little more than shallow cuts through the softer surface materials, but at the great Culebra cut the material which has been excavated varies from the surface clay, readily removed by steam-shovels, to hard basaltic rock, requiring blasting by high explosives before it can be removed. All the material, even the indurated clay, below the softer covering, requires blasting before it can be excavated, although the softer portions need the action of black powder only.

Except the deep cutting at Culebra, through the summit of the continental divide, the most marked work done by the old French company was the dredging through the low marshy lands from Colon to Bohio. There is at present a strip of partially completed canal

about 14 miles long with a bottom width of 72 ft., which may be navigated by vessels drawing 12 to 14 ft., with the exception of a short distance near Colon. Indeed, so much excavation was completed in this portion of the canal, intersecting the Chagres at a number of places, that the waters of that river have abandoned the old bed and now flow through the partially completed canal prism.

DEPRESSION IN CONSOLS.—In explaining the recent sharp break in British consols to the lowest level for the year, *The Times* says:

Motor-cars and the consequent fur coats, the ever-growing costliness of feminine decoration, and the modern habit of dining, uncomfortably and on preposterous terms, at hotels, while the relentless chancellor snips, with his 'abhorred shears,' a shilling out of every pound that we receive—these are a few of the influences which have led investors to forsake the arid austerity of the consols market and to look for a security which will pay them something. At the psychological moment came the Japanese loans, providing a comfortable yield and, for some time, advancing premiums and improvement in capital value. The public learned its lesson readily, and has substituted for the old-time thrift, that used to lay up treasure and invest it, a habit of turning out its tin boxes, realizing its gilt-edged securities, and re-investing in stocks with a higher yield.

There is economic authority for a theory that the price of capital is likely, on the whole, to tend upward in future, from which, if true, it will follow, as a corollary, that the prices of gilt-edged and other securities will tend downward. Economic authority is rather at a discount at present, having lost its edge in the clash of partisan political warfare, but this theory is a fascinating theme, and may well be pondered by those who question the advisability of writing down their securities. Recent experience has been against it, for in spite of the movements of the last few years capital has certainly grown cheaper and more abundant in the last half-century. On the other hand, the organization of industry on the modern scale and the development of the use of machinery and mechanical appliances, cause an ever-growing demand for capital, which has at present outstripped the supply, and may easily justify the economic theorist by continuing to do so. Moreover, it must not be forgotten that the last few years have witnessed the destruction of capital on an enormous scale. The South African war and the Russo-Japanese war are sufficient instances.

When we remember that trade is active nearly all over the world, and also the vast amount of development work that is being done in the comparatively backward countries, we have hit upon another very important reason for depression in gilt-edged securities. The program of railway construction in Canada is a case in point, and almost every report issued by the great South American railways contains the announcement of the proposed issue of a million or two of capital. As for the United States, there is not only remarkable industrial development, and enormous expenditure of capital by railroads and other corporations, but there is also a huge fabric of speculation which has to be financed somehow, and it is at present being to a great extent financed in London and on the Continent. Borrowers complain that the spring of capital in London has dried up; perhaps it is truer to say that it has been connected with New York by hidden pipe-lines, and so has little supply to send down the old taps. It has been calculated that New York at present owes some eighty millions sterling on bills, 'kites' and stocks on this side of the water. This development has undoubtedly affected the supply of money here, and so the price of securities.

Special Correspondence.

Butte, Montana.

Another Company Formed to Develop Old Mine. Important Discovery in the Rarus. Encouraging Prospects on the East Side.

Another large mining company has been organized under the laws of Maine, and is called the Butte Central and Boston Copper Co. The main property of the company is the Ophir mine, in the southern part of the city, with a shaft 525 ft. deep. The company is cutting a station at the 500-ft. level, and will install machinery to sink to 2,000 ft. The old mine has yielded a fair amount of ore and is now being worked in the upper levels, producing 100 tons daily. It carries enough silver and gold to make a paying proposition. Among the promoters are Freeman I. Davison and Robert G. McMeekin, of Boston, and Samuel Hill, of Butte. Other directors are Sir Frederick W. Borden, of Ottawa, Canada; F. Orr Lewis, of Montreal; J. F. Tufts, of Wolfville, Nova Scotia; Morgan Strong and Alexander Robertson, of New York; Lee Mantle, E. G. Blackburn and J. H. Leyson, of Butte, and B. F. White, of Dillon, Montana. The capitalization is \$15,000,000. The company claims to have \$1,750,000 in the treasury, of which it will use about half to get full title to the properties. The Ophir has been worked by several companies in the past and was a paying proposition until silver dropped. The present company is the holding corporation for the stock of the Butte Central Copper Co., organized last spring, which has sunk the shaft nearly 200 ft. this summer. The veins in the vicinity are large, and there is a good body of ore in sight. The object of sinking the deep shaft is to ascertain whether copper ore can be found in the southwest part of the city, as well as on the hill. The company claims to have found a new cross-vein that contains ore high in gold and silver.

The Mountain View mine of the Boston & Montana Co. has opened its main shaft again, the timbering being fully replaced. The operation took nearly six weeks. In the meantime nearly 900 tons per day were hoisted through an air-shaft, and it is expected that the main shaft will soon be hoisting 1,200 tons per day. There are said to be nearly 1,000,000 tons in sight in the mine. The shaft was not only re-timbered for 900 ft., but was equipped with automatic skips, which will expedite the handling of ore. The Manhattan Con. mine of the Anaconda Co. has been shut down for repairs to the shaft. The engine-frame broke early in the week, and as it became necessary to close down for a few days on this account, it was thought well to begin re-timbering, which was much needed. It will take a month or more to finish it. At the same time the Clear Grit mine is, for the most part, closed down, as the ore from that claim was hoisted through the Mountain Con. shaft. The Mountain Con. ordinarily yields about 500 tons of ore per day and the Clear Grit about 50 tons. The output of some of the other mines of the company will be increased, if possible, until the repair of the shaft is finished.

The discovery in the Rarus mine of the Red Metal Co. is being explored. The cross-cut proves the orebody to be nearly 30 ft. thick, but drifting and raising have not yet progressed far enough to prove the full extent of it.—The East Butte Co. has struck a small vein of high-grade ore in the shaft of its Dutton mine, at a depth of about 200 ft. Sinking continues in the several shafts, all the work at present being exploration and development.

The development which has been in progress near the ridge east of the city has developed a number of small strikes of ore, some of which are being worked by tributors, as is the Bertha, on ground belonging to the Bull-

whacker Co. In the Bullwhacker shaft ore was found averaging 4% copper and carrying some silver. Similar bodies had been struck, on what is probably the same vein, in the Maggie and Bertha, and this week in the Montgomery, under bond to the Lewissohns. The Bullwhacker shaft will soon be down to the 400-ft. level, when a cross-cut will be started to determine the character of mineralization below the water-level. It is expected that copper sulphide will be found, as was the case with the mines of the Amalgamated and Heinze, and with the Pittsmont, which lies nearer these new mines. The vein is nearly 100 ft. wide on the surface near the Bullwhacker, and the country near there is traversed by other large veins. If the results are as expected it will add at least one-half to the present copper-producing area about Butte.—G. C. Hopkins, purchasing agent for the Pittsburg & Montana Co., is the purchaser named in a deed of the Lillie claim, near Park cañon, not far from the claims just mentioned. The purchase price was \$125,000. It is supposed that the claim was bought for some unnamed party, probably the company, but the real purchaser has not been divulged. The Pittsmont mine, belonging to the same company, is being rapidly developed and the orebodies explored, but little information is given out concerning it.

The East Butte Extension Co. has declared a 1% dividend, payable October 1. This represents more than 1% to the investors, as most of the stock was sold at 50c., par being \$1. The company owns several claims near the Belmont and J. I. C. of the Anaconda, and has four shafts sinking. It is hoisting 40 tons of ore per day from its main shaft, besides the sinking. F. H. Cooney, the manager, claims that it will soon be hoisting 100 tons per day. New ore-bins are being built. The chief claim is the Westlake, on which the company has two shafts.

The Great Falls smelter, of the Boston & Montana Co., the capacity of which is to be increased one-third, is now receiving 4,000 tons daily, of which about 3,000 is second-class ore. The increased output of the Mountain View mine will tax its capacity to the utmost. There is great difficulty in planning for increased capacity, as the power is limited and former additions to the plant have left it in such shape that it will have to be largely re-modeled. A new stack will probably be necessary, as well as new furnaces and buildings. But the main difficulty will be in securing an increase of power. At present 3,000 h.p. is now being developed by steam to augment the water-power, and the decrease in water in the Missouri river will make still more steam power necessary later in the season. It is thought that the company intends to devise some plan by which power from the lower falls can be utilized. There is a greater fall than where the smelter now is, and it may be considered advisable to build a large power plant there.

Spokane, Washington.

The Annual Report of the Bunker Hill & Sullivan in the Coeur d'Alene. Splendid Production at Low Costs.

The annual report of the manager of the Bunker Hill & Sullivan mine in the Coeur d'Alene district of Idaho, for the fiscal year ending May 31, 1906, has just been made public. It is chiefly interesting for the reason that the Bunker Hill & Sullivan mine is the most productive of its kind in America and is second only to the Broken Hill Proprietary mine, in New South Wales, as a producer of lead and silver. Among notable statements found in the report are the following: The Kellogg shaft was sunk 580 ft. on the incline below the Kellogg tunnel, at a cost of \$38.68 per ft. The shaft has two hoisting compartments, each 5 by 5 ft., and a pump and manway compartment. Experiments have been conducted during the year to determine the most ad-

vantageous method of re-working the mill tailing, which has accumulated to the amount of 2,000,000 tons, and a satisfactory system has been arrived at which permits a profit at even lower prices for the metals than are now obtained. During the year 308,800 tons of concentrating ore were stoped at a cost of \$368,490, or \$1.252 per ton, divided principally as follows:

Detail of Labor and Supplies.	Total for Year.	Average per Ton for Year.
Foremen, bosses, blacksmiths, machinists, tool-packers, etc.	\$ 41,010.01	\$0.133
Timbermen and carpenters	14,467.64	0.041
Miners	105,270.42	0.346
Carmen	8,478.20	0.027
Shovelers	112,902.57	0.366
Power labor	4,929.70	0.016
Repair labor	6,371.20	0.021
Explosives	20,145.30	0.065
Illuminants	6,677.66	0.022
Lubricants	850.84	0.003
Iron and steel	3,102.30	0.010
Miscellaneous supplies	8,144.00	0.026
Timber and lagging	43,083.05	0.139
Power supplies	3,068.40	0.010
Wood	4,453.90	0.015
Stable and stock	920.00	0.003
Exploration charged off to stoping, 484 ft. of drifts, raises, etc.	2,625.39	0.009
Total	\$368,490.58	\$1.252

The mine also produced 38,550 tons of shipping ore, at a cost of \$60,228.37, as follows:

Details of Labor and Supplies.	Total for Year.	Average per Ton for Year.
Foremen, bosses, blacksmiths, machinists, tool-packers, etc.	\$7,058.82	\$0.183
Timbermen and carpenters	2,876.11	0.075
Miners	14,469.93	0.375
Carmen	1,033.06	0.027
Shovelers	19,649.15	0.510
Power labor	685.40	0.015
Repair labor	980.30	0.025
Explosives	2,801.25	0.073
Illuminants	959.46	0.026
Lubricants	66.80	0.002
Iron and steel	437.10	0.012
Miscellaneous supplies	1,223.35	0.032
Timber and lagging	7,185.20	0.184
Power supplies	353.25	0.009
Wood	549.20	0.014
Total	\$60,228.37	\$1.562

Making the total ore mined 347,350 tons, at a total cost per ton of \$1.296.

Tramming was mostly accomplished by means of an electrically operated railroad, which handled all of the above-mentioned tonnage of ore at a cost of \$0.059 per ton. In addition to the ore 507 tons of waste rock were hauled, and timber, lagging, and other supplies were hauled into the mine, which is included in the cost, together with hauling men to and from their work in portions of the mine.

During the year 308,750 tons of ore were concentrated, making the average work of the concentrator 846 tons per day, or say 895 tons per 24 hours of acutal operation.

The cost of concentration was \$64,270.25, as follows :

Details of Labor and Supplies.	Total for Year.	Average per Ton for Year.
General Labor	\$ 7,110.85	\$0.023
Millmen	21,916.75	0.072
Laborers	1,754.25	0.006
Power labor	1,322.17	0.004
Crusher labor	2,540.65	0.008
Repair labor	3,572.08	0.011
Illuminants	928.00	0.003
Lubricants	1,000.10	0.004
Iron and steel	752.99	0.002
Miscellaneous supplies	12,351.43	0.040

Trommel screens	1,226.00	0.004
Crusher supplies	1,990.00	0.007
Wood	2,575.00	0.008
Power	2,495.00	0.008
Total	\$64,270.25	\$0.209

The gross income of the mine was \$4,816,677, of which 43.1% was available for dividends. There are ore reserves, available on May 31, amounting to 1,671,953 tons. The gross assay-value of the ore and concentrate sold was \$4,705,543, from 347,350 tons of ore mined, of which 308,750 tons were concentrated, yielding 46,616 tons concentrate and 4,949 tons slime. In addition, 38,580 tons of ore were shipped direct to the smelters. The total production was 97,566,290 lb. lead and 2,099,084 oz. silver.

The Bunker Hill & Sullivan mine paid its 107th dividend on August 6, the total to date being \$6,966,000.

Calumet, Michigan.

Activity in the Lake Superior Copper Mines. The Keweenaw Co. The Hancock Consolidated. Prospecting at the Caldwell. Other news.

At a meeting of the board of directors of the Keweenaw Copper Co., this week, the reports of development work accomplished were received and discussed. All the directors were present with the exception of Spencer R. Hill, of New York. The directors, including C. A. Wright of Hancock, Capt. James Hoatson of Calumet, Thomas F. Cole, of Duluth and John D. Ryan, of Butte, went from Calumet to the company's mines in Keweenaw county. Capt. Thomas Hoatson, mining director, and C. A. Wright, Jr., secretary and treasurer, who is in charge of the New York office, also visited the properties. Reports from the development on its Medora property, where a new shaft is being sunk in the Medora lode, continue to be encouraging. The construction of the Keweenaw Central Railroad is progressing rapidly and the contractors expect to have the grading finished to Calumet by next January. Men are now engaged in laying rails near the Delaware mine.

The presence of Messrs. Cole and Ryan in the copper country this week led to the report that important plans regarding the future work of the Hancock Consolidated Mining Co. were being discussed. Cole and Ryan, together with the St. Mary's Mineral Land Co., of Boston, own 60,000 of the 100,000 shares issued by the Hancock Co. Capt. James Hoatson, of Calumet, and John D. Cuddihy, of this city, also are in the district, so that a quorum of the board of directors is available. The Hancock is progressing steadily with the unwatering of its 1,000-ft. shaft on the Hancock lode. The water has been lowered to the second level and as soon as the workings are entirely cleared men will be put in the shaft and development started. The site of the proposed vertical shaft, which will tap the Pewabic lode, from which the Quincy mine has paid \$16,000,000 in dividends, has not yet been selected. The vertical shaft will also tap the Hancock and other lodes traversing the lands of the Hancock Consolidated Company.

Explorations on the Caldwell Copper Co.'s property south of the Tecumseh is under way, a diamond-drill being in use. The Caldwell is controlled by the Calumet & Hecla Mining Co. At a recent meeting of the directors the following officers were elected: President R. R. Goodell; vice-president, R. Skiff Sheldon; secretary and treasurer, Courtney C. Douglas, and the foregoing, together with P. W. Nichols and Allan Rees, directors. All of these are Houghton men. The Caldwell property comprises 560 acres lying between the Tecumseh and Rhode Island. The company has an authorized capital of \$2,500,000. A little less than 50% of the capital stock was issued to the original land-owners in exchange for the property, and the Calumet & Hecla took slightly less than 50%, paying cash therefor. The remainder of the capital stock, which is held in the treasury, is under option to the Calumet & Hecla, which, if purchased by the latter, will give the Calumet & Hecla Co. control.

Capt. James Hoatson, of Calumet, has been elected president of the newly organized Cananea Central Copper Co. C. A. Duncan, of Duluth, is vice-president and treasurer, and F. R. Kennedy, secretary. These men hold the same offices with the North Butte Mining Co., and the general and executive offices of the Cananea Central Co. will be with those of the North Butte Co., at Duluth. Capt. Hoatson, beside being president of the Cananea Central and North Butte Co., is vice-president of the Calumet & Arizona and Superior & Pittsburg, and a director of the Butte Coalition, Hancock Consolidated and Keweenaw Copper companies.

Arrangements are being made by the Michigan Mining Co. for the construction of a railroad spur to its C shaft. It will be extended from the main line by the Mineral Range Railroad. Plans are being made for the construction of a shaft and rock-house at C shaft at an early date. It will be similar to those that will be built at the Centennial and Franklin Junior mines, being of the circular type. C shaft is being sunk in the Calico lode, and from that formation cross-cuts are driven to reach the Branch vein and to investigate the Minnesota conglomerate. The Michigan is opening its most promising ground in the drifts eastward from shaft B and extending toward C shaft. The latter is now equipped with temporary hoisting facilities, there being no need of larger machinery at present.

The Mass Consolidated Mining Co. has started a new shaft on its property. It is known as D shaft and is situated 1,400 ft. south of C shaft. The latter is opening promising ground in the direction of the new shaft and therefore the outlook for D is considered encouraging. It is sinking on the Knowlton lode. At C shaft the results are good. Ore shipments average 350 tons daily. After September 1, when the Michigan releases one head in the Mass mill, the Mass Consolidated Co. will double its production. The mine is now shipping approximately 500 tons of ore daily, and with the output and earnings doubled, the stockholders ought to receive tangible benefit.

Salt Lake City, Utah.

Progress at Bingham. Sale of Alta-Quincy Mine. Demurrage on Cars of Ore. Developments in Sierra Madre District.

The ore and bullion settlements last week amounted to \$550,200, and during the same period 221,399 shares of stock were sold on the Salt Lake Stock & Mining Exchange for \$188,712. The management of the Ohio Copper Co., at Bingham, has about completed arrangements to begin sinking a working shaft, which is to be equipped with a hoisting plant capable of going to a depth of 2,500 ft. During the present week shareholders will meet to discuss the matter of limiting the company's indebtedness to \$650,000 and re-incorporating under the laws of some other State than Nebraska.—Owing to the delay in shipment of equipment, the Utah Copper Co. has been unable to get its second steam-shovel working in the removal of overburden from its Bingham property.—The Gold Development Co. has resumed development at its properties near Marysville, which have been idle for several months. M. F. Murray, of Richfield, is manager.—The sale of the Alta-Quincy mine, at Alta, has been consummated, the purchaser being Tony Jacobson, manager of the Columbus Consolidated Co., operating in the same camp. Considerable low-grade ore has been developed in the mine.—The mill of the Columbus Consolidated Mining Co., at Alta, is now operating with two 10-hour shifts, and turning out a car of concentrate daily. There is a possibility of a consolidation of the Odin, California, and Comstock mines, at Park City, being effected. Negotiations have been pending for some time.—Davis Calyx drills are being used to develop the West Quincy mine, at Park City; the machines have been installed on the 400-ft. level. The main working shaft, double-compartment, at the Silver King Consolidated mine, at Park City, has reached the depth of 1,100 ft., and the management reports a change in the bottom which indicates the proximity of an ore-body.

The new Garfield smelter is getting well under headway and it is a matter of only a short time until the entire plant will be in operation. Four MacDougal furnaces are now working and the converters were started

up a few days ago. The plant will handle about 1,200 tons of ore daily when in full blast.

Articles of incorporation of the Nevada Douglas Copper Co. will be filed in this State during the present week to operate the Douglas mine, at Yerington, Nevada, which recently changed hands, the same having been purchased by a Salt Lake and Boston syndicate. The capital stock will be \$5,000,000. The officers will be: President, J. D. Wood; vice president, Frank J. Hagenbarth; secretary and manager, Walter C. Orem, of Salt Lake, who, with W. V. Rice of Salt Lake, A. L. Pearse of London, E. R. Hastings and A. J. Orem of Boston, are members of the board of directors.

The Utah Car Service Association, of which all transportation lines operating within the State of Utah are members, attempted to introduce new demurrage rules, effective on the 28th inst. It was proposed to allow the samplers and smelters only two days' free time for the unloading of cars of ore. The circular announcing this change was met with such a strenuous protest from the sampling and smelting companies, as well as from the producers, that the Car Service Association consented to a modification of the rule. But as it stands, three days is the maximum that a car can be held after receipt without being subject to demurrage charges of \$1 per day. Under former regulations, the samplers were allowed four and the smelters five days free time.

A large body of milling ore has been opened on the 800-ft. level of the Cyclone mine at Stockton. It has been exposed by a cross-cut for 11 ft. The shaft at the Eagle & Blue Bell mine, in the Tintic district, has reached the depth of 1,100 ft. and a station is being cut. A cross-cut will be run to cut the orebody opened on the 1,000-ft. level. Excellent headway is being made with the construction of the new plant of the Utah Smelting Co. near Ogden. The management is in the market for ore and has closed several good contracts with Utah and Nevada mining concerns.

Unusual activity is being displayed in the Sierra Madre mining district, north of Ogden. Recent developments indicate that it will become a good copper camp as well as a producer of lead-silver ore. The management of the Majestic Copper Co. has an opportunity to dispose of its lead smelter at Milford to mine-owners at Good Springs, Nevada, who have opened negotiations for it.—The Skylark Copper Co.'s property, in Beaver county, has been undergoing examination, in the interest of Eastern people.—Copper ore has been struck in the Black Rock mine, in Beaver county, the shaft cutting a 4-ft. vein at 165 ft. depth.

The management of the Bingham & New Haven mine, at Bingham, has announced an initial dividend of 10c. per share on the issued stock, amounting to \$22,600. The company will probably make quarterly distributions hereafter.

Toronto, Canada.

Quartz Mining in the Yukon. Fresh Activity in the Manitou District. News From Cobalt. The Gillies Timber Limit.

The Department of the Interior at Ottawa has received from Mr. Snyder, superintendent of the mounted police at White Horse, Yukon Territory, a report to the effect that quartz mining is experiencing a great boom. Numerous discoveries have been made in the Watson and Wheaton River districts, at points from 15 to 25 miles southwest of Robinson Siding, on the White Horse Pass & Yukon Railway. Samples of rich ore are claimed to run from \$200 to \$600 per ton. Claims are being purchased as soon as staked, prices ranging from \$250 upward. Applications have been made for two townsites, one at the mines and one at Robinson Siding, the nearest

point on the railway. In the neighborhood of Conrad work is being done on about 40 claims, giving employment to some 400 men. The Conrad Con. Co., employing over 200 hands, was to begin shipping to the southern smelters in August. At the Pueblo copper property, five miles from White Horse, extensive operations are being carried on, and it is expected that fully 1,000 tons of ore will be shipped this fall. The various placer fields in the district are yielding well, 1,025 oz. gold being brought from Livingstone creek in one week.

There is a marked revival of activity in gold mining in the Lake Manitou district and neighborhood, largely owing to the introduction of American capital. Anthony Blum, owner of the Laurentian mine near Crystal lake, has decided to handle it as a free-milling proposition. In addition to quantities of free-milling ore, there are deposits of pyrite which are being explored. Chalcopyrite has also been found studded with gold, which in some samples makes up half the weight. Considerable development work has been done during the last few months. The shaft has been carried down 270 ft., a tank cut at the 200-ft. level and a skip put in. Cross-cuts 230 ft. long at this level have tapped rich orebodies. A 20-stamp mill is at work on the ore removed in development. A pipeline brings water from Crystal lake, and a telephone line to the neighboring town of Dinorwic is being constructed. The locations of the Glass Reef Mining Co. on Lower Manitou lake, where work was suspended in December, 1900, are being examined by Edwin H. James, secretary of the company, with a view to the resumption of operations. Buffalo capitalists are investigating conditions on the Pritchard property, near the Redeemer mine, where a test shaft was sunk some years ago, samples from which were said to run from \$12 to \$40 per ton. Walpole Roland is engaged in making tests on behalf of the prospective purchasers. E. H. Page, of Minneapolis, is developing the Page-Holmes property on Contract bay on behalf of several St. Paul investors, and has secured samples of rock containing free gold from a rich 4-ft. vein, which widens as it is followed, and is intersected by a larger one.

The Ontario Government has a force of 30 men employed on the exploration of the Gillies timber limit, near Cobalt, under direction of Prof. Willet G. Miller. A 75-ft. shaft is to be sunk for the development of the silver-ore deposit recently discovered. A rich find of antimonide of silver has been made on the Kerr Lake Mining Co.'s location, otherwise known as the Jacobs property, in the Cobalt area. It is reported that free-milling gold assaying \$1,827 per ton has been found on a location in the southern part of the Cobalt camp. A 6-in. vein, struck at a depth of 12 ft., has been exposed for 250 ft., and work is being prosecuted day and night. McKenzie & Philbrick, in sinking a shaft on their claim on Trout lake, in the Temagami forest reserve, struck a vein of niccolite at 54 ft., which assayed \$1,100 per ton. A drift on the vein exposed a shoot of pure native silver.

Cecil B. Smith, chairman of the Temiskaming & Northern Ontario Railway Commission, states that a Kentucky prospector has made a rich strike of gold in Playfair township, about 80 miles north of New Liskeard. Samples showed on assay about 411 oz. gold in addition to 400 oz. silver per ton. The discovery was made three or four days ago and a big rush of prospectors is anticipated. A branch of the railway, which has already been located by the commission, will pass near the new goldfield. Tenders for construction work will be advertised for in a few days.

Willet G. Miller, provincial geologist, who has been engaged in exploration work on the Gillies timber limit during the summer, has returned to Toronto. He leaves

next week to attend the International Geological Congress at the City of Mexico. He states that although previous to the Provincial Government undertaking to develop the mineral resources of the Gillies limit, many prospectors claimed to have made discoveries, the standing offer of a bonus of \$150 per inch width of vein, to any person who would disclose such discovery, has failed to elicit any information from such alleged discoverers. Despite all rumors and statements to the contrary, the policy of the Government to continue the development of the tract as a public work was thoroughly settled, and work would be steadily prosecuted through the fall and winter.

Johannesburg, Transvaal.

The Coolies and the Posters. Labor Statistics. Mineral Output of the Transvaal. Base-Metal Mining. Tube-Mills for Diamond Washing.

So far the coolies have behaved quite satisfactorily over the new poster, which has been stuck up in the compounds by order of the Liberal Government. There has not been a rush on the part of the coolies to embrace the offer of repatriation, even though it mean a free trip to China. So far the number of applications is between 200 and 300, out of a total of 52,000 coolies employed. The danger is not yet over, but it does not seem likely that there will be a wholesale departure of the coolies. There is still a feeling of uncertainty, however. It is devoutly to be hoped that after two abortive attempts to get the coolies out of the country, the Liberal Government will now drop the Chinese question, and leave the final decision to responsible Government. What that decision will be is, of course, unknown. Many leading men, however, are of the opinion that in spite of all the anti-Chinese talk the decision will be 'pro-Chinese.'

The official labor returns for June show that there are 17,959 whites, 90,882 Kaffirs and 52,352 coolies employed on the gold mines of the Transvaal. The coal mines give employment to 461 whites, and 10,076 Kaffirs. The diamond mines accounted for 664 whites and 5,837 Kaffirs. All other mines and prospects employed 151 whites, and 1,260 Kaffirs. These figures show an increase of 4,458 white workmen over June, 1904. The 52,000 coolies have therefore been the means of employing 4,458 white men in the Transvaal mines.

The Government returns for the statistical year July 1, 1905, to June 30, 1906, show that the mineral production of the Transvaal has increased £3,473,092 over the period 1904 to 1905. The figures are as follows:

Gold production.....	£22,100,707
Silver ".....	66,458
Diamond ".....	968,229
Coal ".....	837,176
Total.....	£23,972,570

Truly a splendid total!

An announcement made the other day by a big gold producer employing Chinese shows the feeling of directors. Owing to the uncertainty regarding Chinese labor, it has been decided not to pay the usual dividend as yet. The dividends being paid by the mines of the Central Rand, run by Kafir labor, are high. A new gold producer in the Central Rand will pay a dividend of 45% this year. Even with the depressed state of things these 'gilt edge' shares stand at figures which do not appeal to the investor. The mine referred to will last about 12 years. On present prices this mine will give an interest of 6%, and return the money. Considering the uncertainty of the future, 6% for a mine investment is none too attractive.

The base metal industry of the Transvaal looks far from cheerful at the present time. Silver mining was tried years ago, and any product of this metal will come as a by-product from lead, or from gold mining, as at present. There were great hopes a year ago that

the Transvaal would become a big tin producer. The proposition that was to "turn out so much tin that the market of the world would be affected," namely 'Sallies,' is just about to close down its mill, after a disastrous run of several months. The shares of this concern stand at five shillings today, whereas a year ago people were paying 140 to 150s. for them. A lead proposition, Edendale Estates, seems to be getting fair results in opening up the property. It is said that it is quite probable that this will turn out a payable mine. Asbestos is coming in for a lot of notice. So far the prospects for copper are not over bright.

Quite a novel idea is a scheme to treat the 'blue ground' (diamantiferous) from the Premier diamond mine by means of tube-mills. A trial run of 1,000 loads has been made. It seems almost impossible for the Premier company to floor its 'blue ground,' as is done at Kimberley, and it is therefore to be hoped that the tube-mill idea will be successful.

London.

Tin Mining in the Malay States. The Cornish Boom. Oroville Dredging. Foreign Capital in the Urals.

The acting Senior Warden of the Federated Malay States in his report on the working of the Mines Department for 1905, gives the total mining revenue derived from all sources as \$9,689,501, against \$9,249,189 for 1904, an increase in 1905 of \$447,312. Of the total amount collected the export duty on tin accounted for \$9,249,627, an increase as compared with 1904 of \$434,939; the export duty on wolfram yielded \$2,213; and the royalty on gold produced only \$11,439, as compared with \$28,148 in 1904. The output of tin is stated to have been 114,221,333 lb.—a decrease in quantity, as compared with the output of 1904, of 1,662,400 lb. The acting Senior Warden sees no cause for alarm in the decreased output, and is of opinion that no evidence is forthcoming to show that the stanniferous deposits of the country are nearing exhaustion. The gold-mining industry was not prosperous in 1905. The total quantity exported was 9,972 oz., of the approximate value of £39,888. The quantity of ore crushed was 67,421 tons, of which all but 200 tons was treated in Pahang, yielding 9,073 oz. of gold. The only mines that continued working in Pahang at the close of the year were the mines of the Raub Austalian Gold Mining Co., where operations were carried on vigorously throughout the year, a force of some 800 men being employed.

Very little information of a genuine character is available regarding the various new enterprises launched in Cornwall on the tin boom; but the returns show that the old established mines are jogging steadily on. It is reported that at Clitters United, the electric pumping plant has been completed, and is expected to commence permanent work at an early date. The directors of Clitters, in view of the developments, have announced their intention to commence the payment of dividends with an interim distribution of 6d. per share. Clitters United claims to be the pioneer in Cornwall in the economical treatment of complex ores. The shareholders subscribed £40,000, and ores of that value have been sold, the profit being re-invested in the mine. The Hingston mine, which is a part of the set, has been drained without fresh capital being called up. The Dolcoath report for the half year ended June 30 shows an advance all along the line. It states that the profit earned amounts to £40,165. Exclusive of slime, the black tin sold was 858 tons 13 cwt., of which the average price realized was £107 11s. 8d. per ton, as compared with 812 tons 4 cwt. 3 qr. 22 lb. sold in the previous half year at an average price of £93 7s. 6d., showing a rise of £14 4s. 2d. The slime

sold amounted to 61 tons 11 cwt. 3 qr. 20 lb. at an average price of £79 6s. 2d. per ton, while in the previous half year 54 tons 13 cwt. 3 qr. 27 lb. were sold at an average price of £69 16s. 3d. per ton, showing a rise of £9 9s. 11d. The quantity of tin ore treated was greater by 1,462 tons; 53 tons 5 cwt. 3 qr. 27 lb. more black tin was sold; the quality was 1.22 lb. per ton of ore better; the average value of a ton of ore treated was 6s. 11.04d. higher; and the selling price of black tin was £13 15s. 5d. more than in the previous half year. The general result was an increase of £17,598 in the amount realized, equivalent to 22%. Compared with the half year ended June 30, 1905, the increase is 44½%. The total receipts on profit and loss account give an increase of £18,178. The profit for the half year, added to the balance as per last account, £6,997, makes a total of £47,162. From this must be deducted the amount written off as allowances for depreciations on buildings, plant, etc., £9,482, leaving a balance of £37,679. The dividend recommended at the rate of 15% per annum will absorb £24,296, leaving £13,383 to be carried forward. The starting of Wheal Alfred, at Perranporth, in the once flourishing parish of Perranzabuloe, is reported. In this set there are said to be no less than seven lodes, forming a junction with a main lode which is 13 ft. wide. Most of the mineral raised to the surface is blende and copper. The company has a capital of £30,000. North of Wheal Alfred is the inactive, but celebrated Wheal Leisure, formerly a great copper producer; and northeast is Budnick, which has been worked in a small way by a local party for several years.

It is feared that with the flotation of new companies the Cornish labor difficulty is likely to become more acute, and it is urged that the Cornish miner, of all men, should be the last person in the world to object to a foreigner working in the Cornish mines. He has long neglected the home industry, and has invaded foreign fields with a nerve that does him credit. Having laid down the rule that he himself is free to go where he wills, the Cornish miner could not logically object to Chinese or any other alien laborers coming to the Duchy to dig for him. Another difficulty in the way of obtaining new capital for tin mining in the county is found in the 'dues' or royalties. It would be expecting too much from the owners of the soil to ask them to put their hands in their pockets and subscribe for shares in new ventures, but it is a pleasant recollection that in the case of Wheal Grenville, some few years since the ground landlord helped the shareholders to the extent of some £5,000 to furnish the property with the necessary plant, etc. He now gets as his reward one-fifth of the profits on the present scale of working, and no one having regard to his liberality, begrudges him the money. Other ground landlords have responded to similar appeals in a measure, but if the 'lords' would go further and agree to commute their royalties for shares in the mining companies or to take them out in a percentage on profits, a heavy incubus would be removed from the leading Cornish industry.

The two last weekly gross returns recorded by Oroville Dredging Limited—\$24,000 and \$17,000—confirm the report that some of the old dredges have been thoroughly overhauled and improved so as to increase their capacity considerably. The profit from Stratton's Independence for July—£3,000 from 1,559 tons of shipping ore averaging 2 oz. 8 dwt. per ton—is slightly better than for the preceding month. The future of this mine is now thought to depend on the solution of the low-grade ore problem which, according to rumors, is about to develop a new phase.

The British commercial agent in Russia reports that the sale of several big mineral enterprises in the Urals has been made to a syndicate of foreign capitalists. The

sales comprise the copper mines in the Atbassarski district of the province of Akmolinsk, the silver-lead works with mines in the Turgaiski territory by the river Kara-Turgai, and the coal deposits in the same territory along the river Bai Konur.

A cable from Cape Town announces that the decision of the English courts on the subject of the liability of the De Beers Co. to pay income-tax in England (noticed in my correspondence last week) gave rise to a discussion in the Cape House of Assembly, when the following resolution was unanimously carried: "That this House regrets the action of the Imperial Government in levying the income-tax on companies which originated in South Africa, and which to all intents and purposes are South African undertakings, and desires most respectfully to point out that such a proceeding may have far-reaching consequences prejudicial to the best interests of the Empire."

Apropos of 'sand-bagging,' Sir Francis Carruthers Gould, who began life as a stockbroker and who for his clever political caricatures is known as the "greatest asset of the Liberal Party," speaking at a dinner the other night, is reported to have said that the Stock Exchange was sometimes scoffed at; but in his judgment there was no place where the standard of morality was higher, or where the line between right and wrong was more sharply drawn.

Bisbee, Arizona.

The Shattuck Tramway. Sale of Mines in the Huachuca Mts. Progress at Tombstone.

A plan is being worked out for the installation of electric power throughout the Copper Queen mines. At the Calumet & Arizona mines the Shattuck-Arizona has been added to the list of producing mines. Just two years after the first work was done on this property with a windlass, preparations for ore shipment were complete. On account of the inaccessibility of the Shattuck by railroad, it was necessary to build a 3,200-ft. aerial tramway to the nearest point where a spur could be built. The tramway is supported by 14 towers, varying in height from 12 to 40 ft. The towers are constructed of 12-in. timbers and are set on concrete foundations. The orebins at the loading end of the tramway have a capacity of 1,000 tons. The lower terminal, where the railway cars are loaded, is so constructed that five cars can receive ore at one time. The ore will be loaded directly from the tram buckets into the railroad cars. The tramway will handle 500 tons per diem. The Shattuck people will ship to the Copper Queen smelter. It is expected, however, that they will construct their own smelter next spring. At present two large orebodies are being opened up on the 700 and 800-ft. levels. There are a number of stopes being worked on each level in sulphide and oxide ore. Development work is being prosecuted on the 600, and at the present time the drift is in vein matter and iron ore. On the surface, the steel head-frame is in position and ready for service. The old hoisting engine is being moved to make room for the installation of the hoist borrowed from the Junction. The Allis-Chalmers hoist is expected to arrive by September 15. The Junction hoist will be used until that time. The new 25-drill Sullivan compressor is expected to arrive about September 5.—At the Denn-Arizona, driving continues on the 1,000-ft. level to make connection with the Saginaw. As soon as the drift is north of the diamond-drill bore, a cross-cut will be driven to the latter point. When the drill was put down a year ago, it went through 27 ft. of copper ore, so it is expected that a large body will be opened by the cross-cut. The drift is in altered limestone and is showing favorably. Sinking was discontinued in

the shaft, on account of the breaking of a pump. As soon as this is repaired, sinking will be resumed.

It was learned a day or two ago that the Princeton Mining Co., in the Huachucas, had purchased a large amount of adjoining property from Berner & Campbell. These properties are reported showing up well. The Amalgamated people are operating there under the name of the Butte & Arizona.—At Tombstone the new pumps are doing well. Ore shipments from the Tombstone Con. are about as usual.—The Cananea-Central deal is still attracting the attention of the public. It is known that the company has acquired some of the best properties in the Cananea district, and it has already started operations on a large scale.

Cripple Creek, Colorado.

Healthy Activity. New Exploration Company Organized. A Rich Strike. More Mills Being Built. A Peculiar Decision. A Record Shipment From the Vindicator. The Telluride Mill Nearly Ready. The Drainage Adit.

A new company has been formed in the district by several prominent operators titled the Mines Exploration Co. This company will take over and work several promising properties which are now lying idle. The directors include such men as Spencer Penrose and Chas. McNeill of the United States Reduction & Refining Co., C. C. Hamlin of the Granite mine, K. R. Babbitt, and G. C. Jacklin. Mr. Jacklin is general manager of the Utah Copper Company.

The Isabella Gold Mining Co. has bought for its new cyanide plant, now in course of erection, some of the machinery and the vats of the Los Angeles mill, which was burnt to the ground about a year ago. The vats were found to be very little injured by the fire and will shortly be installed in the new mill, which will be running in about two months.—The Strong mine on Battle mountain has again resumed operations after a partial closing down due to the accident several weeks ago to the pumping plant. The machinery is now at work again and it will only be a short time before the lower levels of the mine are accessible for work.—Carlton and associates, lessees, operating on the Lonaconing on Beacon hill have been shipping some ore of good grade. A four-foot vein which is being worked at a depth of 300 ft. is producing about four cars of shipping ore per week, which give returns around four ounces.—Several more lots in the town of Independence have been sold to the Vindicator Gold Mining Co. by the Western Packing Co. for the site of the proposed mill the Vindicator company intends to build.

Marsh, Hodges & Co. operating on the Little Clara claim of the Work company's property, have made a rich strike during the last few days. Work is being carried on through the Moffat tunnel where a rich streak consisting of sand and talc has been cut, carrying free gold. A car per day of ore running on an average \$40 per ton is being shipped from this place. The Columbia Mining & Development Co. has erected a large ore-house at the Chicken Hawk mine on Guyot hill. Ore of good grade was cut in the shaft at a depth of 500 ft. and the shaft was then sunk another hundred feet so as to obtain sufficient stoping ground.

The second clean-up within a month has been made by the Home Run cyanide mill which is treating ore from the Home Run claim of the Schuylkill Gold Mining Co. and the Climax No. 2 of the Little Puck Co., both of which are situated on Squaw mountain. The gold brick obtained is valued at \$1,400. Sherman Bell is general manager and Dan Mahoney superintendent. It is rumored that another small cyanide mill is to be erected in the district. The Blue Flag Mining & Milling Co. on Raven hill is to build a mill having a capacity of 100

tons per day. Large bodies of low-grade ore have been opened up on the second and third levels of the Blue Flag property and good profits are expected to be obtained from this ore by cyaniding.

The El Paso mine on Beacon hill shipped three cars of five-ounce ore last week from the Little May and Beacon Hill-Ajax claims, where operations are being carried on by lessees and the company. The water has risen in the El Paso shaft lately to the 600-ft. level, and from recent developments it is thought that there will be enough ore above this level to keep the mine in the producing stage until the completion of the drainage adit, which, if started now, should reach the El Paso property within three years.—The Cody shaft of the Granite mine, on Battle mountain, under lease to Messrs. Fry, Becker & Travell, after a shut down of four or five days on account of bad air caused by the wet weather, has resumed operations and will drive the 125-ft. level to connect with the ore-body, which has been stoped by the Portland up to their boundary.

A peculiar decision was rendered by a Justice of the Peace last week, in the case of the people vs. A. R. Pierce; Mr. Pierce was charged with assault with intent to kill. It was proved by five different witnesses that Pierce entered the Christmas shaft-house on Bull hill and at the point of a gun, which he admitted was loaded, ordered the engineer to stop running the hoist which was lowering the men about to go on shift. It was held by the Court that this action did not constitute a cause of action and the prisoner Pierce was discharged. A decision of this kind, if upheld, renders it perfectly lawful for any person in the Cripple Creek district, whenever he feels so inclined, to go upon a property and shut it down in the above manner and no redress can be had.

The 40-drill compressor, which was ordered some time back from a New York firm for the Golden Cycle mine, on Bull hill, has not yet arrived. The foundations are all ready to receive this large piece of machinery, which, when working, will materially aid in the increase of the Golden Cycle output.—The removal of the Vindicator dump is steadily progressing, the waste being shipped away by the railroad free of charge, they are using it for the filling of bridges and trestles on the various lines of the district. The Vindicator mine made a record of 346 mine cars for one day's hoisting last Sunday, which did not include several cars of waste, and made a total of 175 tons of ore hoisted in one day. Few properties have the ore reserves to supply the material, and for handling such an enormous tonnage there are few hoists in the camp capable of doing so in 24 hours. The average grade of ore on 1,700 tons for August, from the Vindicator, will not vary more than a dollar either way from two ounces per ton.

The management of the Telluride mill at Colorado City announce that they will be ready to treat ore October 1; they have, however, ample room for storing ore that will be shipped in the meantime, principally from the Findley. The Golden Cycle Gold Mining Co. purchased the Telluride mill and ore will be treated from that property and the Findley, while other mines in the vicinity of these properties will contribute of their output. It is gratifying to know that the plant has been thoroughly overhauled and put in working order in so short a period of time. It is replete in the latest devices of machinery, and the trust faces the fact that the management is prepared to meet any reduction in rates it may make.

Advices from Colorado Springs state that \$500,000 of the amount necessary to construct the drainage adit has been raised, another \$100,000 is in sight, and there is not the slightest doubt but that the remaining \$100,000 necessary will be forthcoming within a week.

Mining Summary.

ALASKA.

An electric railroad will be built from Ketchikan to Unuk river next year by the Unuk River & Smelting Co., according to J. W. Daly, manager of the company. It owns a wagon road to their Unuk river mine, but requires better transportation facilities. The length of the road will be 42 miles and construction will be started early next spring. The ore which has accumulated on the dumps carries silver and gold. Twenty men are employed stoping in the company's Unuk river property, and many more will be required when facilities have been provided for shipping the ore in a less expensive manner than at present.

ARIZONA.

GRAHAM COUNTY.

(Special Correspondence).—N. L. Jenkins, superintendent of the Home Copper Co., has shipped a large sample of the ore of that company to the Territorial Fair, at Phoenix. This company is now sinking a 100-ft. shaft, and will run an adit 600 ft. to cut a body of ore which assays on an average 30% copper. The rock in which they are now working assays 5% copper, with \$4 gold and \$10 silver per ton.—Word has been received here of a strike on the 150-ft. level of the total wreck mine, a lead-silver proposition. This mine is under new management. The old company which worked it sank a shaft to a great depth, but this last strike proved that the old company had gone away from the larger orebodies. The new management, among whom are Epes Randolph, E. P. Drew, C. T. Roberts, and L. J. F. Jaeger, began work by sinking 560 ft. away from the old shaft. It is believed that the strike is near the junction of the main vein and a smaller vein. It is thought probable that the company can now stope from 600 to 800 ft.—H. K. Burtch, in charge on the construction of the concentrator recently completed by the Detroit Copper Mining Co., has finished his work here, and gone for a two months' vacation. On his return he will accept a similar position for the Montezuma Copper Co., at Nacozari, Sonora, Mexico, a property owned by the Phelps Dodge Co. George Booth, Mr. Burtch's assistant, will assume charge here.—At the regular annual meeting of the New England & Clifton Copper Co., recently held at Portland, Maine, with one exception, an entirely new board of directors was elected. These two companies, under one management, own some of the most valuable properties in this district, but no satisfactory work has been done on them for over three years. With the new board of directors, however, it is hoped that affairs will change, and that these properties may become dividend payers. The tramway, which has been under construction for some time but which, owing to lack of funds, is still uncompleted, will be finished at once.—At the Gold Belt Development & Reduction Co.'s properties a solid body of manganese-copper ore was uncovered last week. Assays show 30 to 35% copper. The shaft is now down only 15 ft., yet about \$4,500 worth of ore has been taken out, which will be shipped to the Detroit Copper Co.'s smelters.

Morenci, August 25.

NAVAJO COUNTY.

It is reported that large tracts of coal land have been discovered and located in the Mogollon mountains, in this county. Thomas Cunningham headed the prospecting expedition.

YAVAPAI COUNTY.

The Rincon Mines Co. is boring for water near Congress Junction.—The Hite Co. has stopped work on the shaft for the present on account of water, but will resume as soon as they can get a pumping plant installed. The shaft is over 400 ft. deep, and there are 800 ft. of drifts. R. J. Rice is superintendent.

CALIFORNIA.

AMADOR COUNTY.

At the Kennedy mine, last week, the non-union miners, Italians and Slavs, went on strike to the number of more than 100, to enforce the placing of safeties on the skips.

About 50 men, members of the Western Federation of Miners, refused to go out with the foreigners, although in sympathy with the request for the protective appliances; as they could not sanction the acts of these men, for nothing had been done regularly in the union with regard thereto, and they looked upon the strike as an effort to force them into a secondary or subordinate position.

NEVADA COUNTY.

With a capital stock of \$1,000,000, the Eclipse Mining Co. has been incorporated under the laws of South Dakota. W. B. Simmons is manager and superintendent. The company will develop the Eclipse mine at Gold Flat, near Nevada City, on which considerable work has been done.—The Sultana Co. will build a trolley-line for the transportation of ore from the Sultana mine, formerly the Green Mountain, to the Prescott Hill, a distance of 2,800 ft. Building will soon commence on this undertaking. Ten three-ton cars will constitute a train. The cars will cross the ravine at the Prescott Hill shaft on a high trestle, and will be hauled direct to the rock-breaker in the head-frame. Eventually the Sultana will be worked through the lower levels of the Prescott Hill. The five-stamp mill at the Sultana may be abandoned later, or as soon as the 20-stamp mill at the Prescott Hill shaft is ready for operations.

W. Baltz, F. Bishop, D. Whilden, and other miners have a lease on the Reward mine near Nevada City. It is the intention of the lessees to erect a hoist. When the Reward was worked in 1900 it produced some rich ore and a small mill was kept running there for several years.

SAN BERNARDINO COUNTY.

The smelter at Needles now has in its ore piles \$250,000 worth of ore. With the supply on hand and the ore already purchased and being received, the smelter will run steadily for a couple of months. If the coming season should be one of successful development of the prospects around the country, the smelter will receive custom ores sufficient to keep it in continuous operation. With the receipt of ore from the Copper World property of the company and the completion of the copper furnace, it is thought that one of the stacks will be running all the time, and a great portion of the time two will be in operation.

TUOLUMNE COUNTY.

(Special Correspondence).—The Spring Gulch mine, situated southeast of Tuolumne, has been bonded to Truman Schench, of Salt Lake City, who represents Utah and Colorado capitalists. Since the company, which until a few weeks ago worked the property, forfeited its bond, a strike was made by the owners in a raise between the 400 and 500-ft. levels. The present bondholders made a substantial payment on the purchase price when they took the property.—Paul F. Green, a local mining man, has purchased El Oro mine, situated two miles south of Tuolumne, and will erect a mill on the property. The adit, 290 ft. long, will be extended and stoping commenced.—Work has been started at the Columbia mine with a force of seven men. This property recently changed hands. It is situated near the town of Columbia.—Preparations are being made for resuming operations at the Hope mine, in the eastern suburb of Sonora. It is the intention to start the mill in the near future. The Hope is a combination pocket and milling mine and yielded largely until recent years. It is owned by local people, Mrs. Julia Ralston, of Sonora, owning the largest interest.

Tuolumne, August 27.

SISKIYOU COUNTY.

(Special Correspondence).—Mining in this section has been active during the past eight months.—The Jumbo near Snowden, in White gulch, is running five stamps on ore stated to return \$12 per ton on the plates, with a general average of \$6 to \$8 per ton. The owners are Holman & Co. The recent litigation on the Lanky Bob mine having been settled, the present owners, under the superintendence of Mr. Poleon, are developing the property and erecting their mill, which will soon be in operation with G. E. Bateman as millman.—The Moltry mine on Tanner mountain, near Sawyers Bar, with \$40,000 of ore blocked out, is handicapped by a lawsuit, a condition not unusual when a mine becomes

of value. The latest reports indicate an early settlement of the difficulties.—An aerial tramway to the south fork of the Salmon, where the mill will be situated, is being considered. The vein is from 18 to 30 in. wide, and the ore will, it is claimed, average \$30 per ton.—Some excellent ore has been found in the Highland mine in China gulch, much of it being specimen rock. The owners are Letherow & Co.—At Taylor lake the Harris mine is being developed. Several pockets have been found recently, beside average ore. The vein is usually 15 ft. wide and in some places 25 ft. The two-stamp mill is running on excellent ore.—Five stamps are running at the Advance mine under direction of Mr. Brokaw. This property is being thoroughly developed. It is stated that \$100,000 has been blocked out in the mine.—Near Sawyer's Bar, little hydraulic work is going on, it being now late in the season for water. About the only property under way is the Ball mine, now owned by the California Con. Mining Co., of Boston, Mass., under the superintendence of Charles W. Raymond, who has had charge of the work since last January, when the present company took hold. As long as water was sufficient the 20-stamp mill was in operation. Since about May last the lower mines on the Mountain Laurel group have been systematically developed. The upper levels have been connected with the lower by shaft and the pay-shoot found to be more extensive than supposed, the previous owners having been stopped by litigation, just a few feet short of high-grade ore. This pay-shoot shows a width of one to four feet of ore-ribbon rock in black slate. The 100-ft. level is reported to show a pay-shoot over 200 ft. long, the ore of which will average three to four feet and assay \$15 gold per ton. The ore is free-milling with 1 to 3% sulphides assaying \$60 to \$150 gold per ton. A drift is being advanced on the 230-ft. level.—Plans are being made to get electric power at Sawyers Bar, with a transmission line about four miles to the mill. This is likely to be done next season. The indications are that the mine will be thoroughly developed before further improvements are placed on the property. Wayland H. Young is manager.—About 10 miles southerly from the Ball mines are the King Solomon mines, owned by the Canyon Mining Co. of New Hampshire. This property is at present idle, having been developed during the past winter, but it is reported that active operations will begin as soon as the new wagon-road is extended to these mines, when machinery can be hauled at reasonable cost.—The Copper claims, below Bennett, at Nordheim, on Crapo mountain, 30 miles from Sawyers Bar, are showing excellent copper and gold ore, but as work has only just been started it is too early to make predictions.

Etna Mills, August 25.

COLORADO.

PARK COUNTY.

(Special Correspondence).—Several adits are being driven in the vicinity of the London mine, which is the largest producer in the county, shipping 50 tons of ore per day. It is reported that this mine is producing over \$1,000,000 per year.—The Pawnee Gold Mining Co. has about 400 ft. of adit. It is driving on a fissure and estimates it will strike ore within 200 ft. The company is composed of Rochester, N. Y., and Iowa people. A. M. Anderson is manager.—The Butte Gold Mining Co. has men at work driving in Pennsylvania mountain directly across from the London, on the fault. The adit is in over 500 ft. The mine is controlled by the owners of the Vindicator mine, in the Cripple Creek district.—The London Extension Mining Co., composed of Ohio people, claim to have reached the same character of ore as that taken out by the London Co.—The South Mosquito Mining Co., Carnahan, Moffat & Mosher, owners, recently installed a power-plant. The adit on this property is in 600 ft.—C. E. Street, manager of the Ophir mine, has several hundred feet of development work on the property.—The Clipper Con. Mining Co. recently made a shipment of high-grade ore.—The London-Twist is still driving its adit. The company has been working for two years in hope of tapping the old London vein.—The New York, above the London-Twist, has been developing for several months and has resumed shipments.—The Hock-Hocking mine is again shipping good ore.—Toledo, Ohio

parties, are developing what is known as the Broom of the Hills mine. P. T. Rigg is in charge. — W. E. Thorne, manager of the Snowstorm Hydraulic Co., has a large force at work on the placers. Three giants are in operation. A clean-up will not be made until they close down for the season, but it is believed they are operating in good ground, as it was thoroughly tested before starting. Work has been handicapped by the delay in delivery of new pipe and by the scarcity of men. Nearly every district in the State reports a shortage of men. — R. S. Bartley, of Denver, has a lease on the small mill at the town of Montgomery, and is getting same in shape to handle ore.

Alma, August 24.

SUMMIT COUNTY.

(Special Correspondence).—Affairs at the Oro mine are now straightened out, and the mine is in shape for operation. The Wellington Mines Co. is reported to be endeavoring to secure an option on this producer to consolidate it with its other holdings.—The Helen group of claims, situated at the junction of Australia and French gulches, below Bald mountain, has been leased to Griffith & Engle. This property contains large veins of high-grade, free-milling gold ore, and with a mill at the mine, could be made to pay handsomely. The lessees intend to install a hoisting-plant and sink a shaft in the gulch on a quartz outcrop 12 ft. wide, the ore of which assays well.—Dean & Sullinger have made a rich strike on the Vossburg, on Mount Helen. The situation of this vein is such as to make it difficult of access, and it will take some time to get connections made for transportation.—The Bullion King is still making a good record under the lease of Foote & Hight. High-grade zinc ore is the chief product.—The new mill and reduction works on the Wire Patch are nearing completion and are expected to start operations early next month.—The Pennsylvania mine, at Argentine, is shipping ore regularly, as well as running its 40-stamp mill and producing a good grade of concentrate.—The King Solomon, at Frisco, is making good progress with its main development adit. The president, F. C. Dinsmore, brought a party of Eastern investors from Denver to see the property.

Breckenridge, August 24.

(Special Correspondence).—The Country Boy mine, on Nigger Hill, is proving a bonanza to the Lanyon Zinc Co., of Iola, Kansas. Since this company took the lease on the property they have mined and shipped over 1,000 tons of high-grade zinc ore. During the month of July over 450 tons were sent to the zinc works at Iola. This ore ran nearly 50% zinc. The ore is granular and has the appearance of concentrate and is easily mined, being picked down and shoveled into the cars without blasting. On each side of the main streak, which averages three feet in width, there is a good width of lower grade ore which is being piled for future treatment by concentration.—At the Kitty Innes an increased force of miners has been put to work in the lower adit. After driving this 60 ft. further a raise will be cut in the ore-shoot to connect with No. 2 level, when stoping will commence. The outlook of this property is exceptionally good.—Coffelt & Deane are now working the June property under lease, and shipping high-grade gold-silver ore.—Montezuma camp is showing up well this year and many new enterprises are now being organized. The Lenawee Mining & Milling Co. now has its mill completed, and stamps dropping. This company has secured control of the Fisherman mine, which is now furnishing an abundance of ore for the mill. The Little Jumbo property, which has a fine record among the shippers of the camp, is now being operated by E. W. Fairchild of Montezuma.—The Lucky Baldwin, on Collier mountain, another shipper of high-grade ore, is being worked by A. L. Harrison and George Worthington. The ore runs high in copper, and shipments of \$60 ore is not unusual.—Orizaba is the name of a new company operating on Wise mountain, under the management of S. F. Stoughton.—The Braganza, on the north side of Collier mountain, is to be worked vigorously this summer. Mr. Nikirk is now having the road fixed for hauling the ore to Keystone.—Swandyke Camp is showing signs of renewed activity, on account of the general improvement in mining matters in Summit county.—Windy moun-

tain was the scene of an important strike last week by C. F. Appleman, who uncovered a vein of lead ore two feet wide assaying \$50 per ton.—In the Three Kings, Eibs & Co. have reached their main vein by a cross-cut adit in Sheep mountain. Ten to fifteen inches of high-grade zinc ore is now shown. The shaft on the I. C. N. property is being sunk on a vein, the ore from which assays 15 to 20% zinc and 15 oz. silver per ton. C. H. Johnson has charge of this work.—P. L. Cummings reports a good find of copper on his property on French pass, near Mount Baldy. The property is difficult of access, being above timber line, but the quality of the ore is such as to warrant operating under the difficulties of transportation which attends such situations.

Breckenridge, Colo., August 24.

(Special Correspondence).—Near the top of Hoosier Pass, John L. Roberts, of Alma, has begun operations on the old Bemrose mine for Elmer Loring, of Brockton, Mass., president of the Hoosier Pass Gold Mining Co., who is at present at Breckenridge looking after his mining interests. The shaft on this property is down 118 ft., with a cross-cut of 100 ft., where the vein was cut. It is the intention to sink 400 ft. deeper. The mine is equipped with hoisting plant and surface buildings. This old mine has been worked spasmodically for years, but it is now the intention of the Eastern owners to develop it extensively.—A short distance from the Bemrose, Mickey Howe is developing the Wonderful mine, and also operating the Senator, farther down the hill, and near the head of the Blue. In the vicinity of the Senator, Arthur Howard has charge of the O'Reilly Gold Mining Co.'s property for Boston people. The Governor mine on the Blue, above town, has been in litigation for a number of years, but the difficulty is about to be settled and operations again started. This was a large producer at one time.—Kennedy & Case are prospecting in McCullough gulch, where they claim to be finding good ore.—B. F. Anderson, manager of the Old Union mine and mill, is treating 45 tons per day in the mill, which has a capacity of 100 tons per day, but owing to the scarcity of men he is unable to produce a greater tonnage.—The Reliance dredge in French gulch, under the management of Ben Stanley Revett, has discontinued operations for a few days on account of a broken shaft. Mr. Revett is of the opinion that four or five new dredges will be built here next year. He expects to install another on his property. He is also testing ground on the old North American property, for which he was manager at one time, with a view of taking a lease on it. Should the ground prove what he thinks it to be, and the lease be granted, he will build a dredge on that ground.—About 500 tons of zinc ore is being extracted at present from the Country Boy mine, a short distance above the Old Union mill, in French gulch. The ore averages over 50% zinc by the carload. The property is being operated by the Lanyon Zinc Co. It is understood that an adit is to be driven from the bottom of the gulch. The ore is of such a nature that it requires no blasting. Occasionally the miners are obliged to blast the walls where the vein narrows, but on the whole, very little powder is used in the mine.—Across the gulch from the Country Boy, the Wellington mine is being operated. The control of this property has been sold by R. W. Foote to Kansas City parties. The final payment is nearly due, and when made it is stated they intend erecting a mill. They have a large amount of medium-grade ore on the dump in addition to that blocked out in the mine.—Some work is being done at the Lucky and Minnie properties by Chas. Putner, of the Wire Patch.—The old Jessie property, on Gold Run, is being operated by lessees—James T. Hogan, president, and C. F. Gilbert, manager. At present they are operating with 25 men, but would put on more if they were available. The mill contains 40 stamps, and is yielding a concentrate for shipment.—This district is enjoying a good, substantial prosperity and with the present price of zinc and lead there is no reason why it should not continue.

Breckenridge, August 25.

IDAHO.

BLAINE COUNTY.

The Lipman Mines & Tunnel Co., under direction of M. H. Lipman, is driving an adit near Hailey that will tap

the Bullion veins at a depth of 1,200 ft. The long adit being run on Boulder creek by a Boise company will develop another district near Hailey.

Two feet of ore have been cut in a raise from the adit driven to tap the Galena Belle and other veins in the property of the Carbonate Hill Mining Co., situated on Cherry creek, two miles east of Galena. Four samples taken from the vein assayed from \$60 to \$160 per ton, of which 48 to 60% is galena, 40 to 200 oz. silver and \$7 gold. The long adit was run to tap another vein that outcrops in the company's property. An exploring drift had been driven 20 ft. in this body.

WASHINGTON COUNTY.

In the Warren district, shipments of bullion have recently been made from the Silver King mine averaging about 225 lb., being the result of a 40 days' run. The mine is reported showing up well and some bodies of ore of good grade are being opened.

MONTANA.

FERGUS COUNTY.

George M. Nelson of the Chicago-Montana Gold Mining Co. is in St. Paul, Minn., arranging to re-open the company's mines near Gilt Edge.

SILVER BOW COUNTY.

Copper production is being handicapped somewhat in Butte by lack of miners. Never before in the history of the district has there been a lack of competent miners, but at present nearly all the big companies are short of men and some companies are offering to pay above the union scale. Shaft men, ordinarily paid \$3.50, can get \$5 per day, while the Pittsburgh & Montana Co. is paying ordinary miners \$4 per day. The labor shortage is responsible for the decrease in the output of ore and copper.

NEVADA.

NYE COUNTY.

(Special Correspondence).—Notwithstanding the boom at the new camp of Monarch, which has taken hundreds of people from Manhattan, Tonopah and Goldfield, Manhattan is still prospering. Last night the news came in that a strike had been made on the Searchlight claim, one mile northeast of town, where a vein eight inches to one foot wide, averaging \$400 per ton gold, was found. A rich stringer two inches in width was found on the surface of the Searchlight claim several weeks ago. A shaft was started below this find, and at a depth of 50 ft. a cross-cut was started to strike this vein, which it encountered last night, as stated above. The ore is being sacked.—A new placer discovery was made on the property of the Manhattan Whale, and when traced, was found to extend into the property of the Manhattan Crescent. It is said 34 oz. of gold was taken from the ground yesterday by means of dry washers. This eclipses all other placer discoveries in camp to date.—A contract has been closed for extending the cross-cut from the 75-ft. level on the Manhattan Cowboy Mining Co. From indications on the surface, a large vein will be found within the next 25 ft., at a depth of about 120 ft.—In the adit of the Georgy group of the Manhattan Nevada Gold Mines Co., the vein is widening and the ore increasing in value. The vein cut a few days ago in the breast of the adit is five feet wide and pans well.—The Toquima Copper Co., owning copper deposits a short distance east of the Con. Manhattan and Manhattan Mammoth properties, at East Manhattan, will build a concentrator.—Some samples of ore were brought to town today from the new camp of Monarch, which assay high in copper, as well as carrying payable quantities of gold and silver. Almost every merchant of means in Manhattan and Tonopah will have branch stores in the new camp of Monarch. Loads of supplies and lumber are now on the road, and building is in progress. Fifty-five frame buildings will immediately be put up. The town has increased from seven tents a week ago to nearly 75 today.

Manhattan, Nevada, August 25.

EUREKA COUNTY.

The Eureka district is developing rapidly and the present season has seen a notable change in every way throughout

this region. A large number of the properties, whose achievements in the early days are matters of history, are being prepared for production. Within the past 10 months 45 new locations have been made. Among the new mines, the Van Norton is producing shipping ore. Numerous properties, with abundant tonnage of low-grade ore, which could not be successfully operated under the old rates for transportation, are being worked at a profit under the new condition of affairs. Everything is contributing to the prosperity of both the high and low-grade propositions in the district. Operations are handicapped by insufficient railroad facilities. All the ore shipped over the road has to be transferred by shovel from the narrow-gauge to the broad-gauge cars at Palisade, for the reason that sufficient labor cannot be secured, either in Nevada or the surrounding States, to complete the construction of the ore transfer-bins. — From the United States mines on Ruby hill, ore shipments are being made as fast as the railroad can haul it away, and with improved transportation facilities a still greater tonnage will be sent from these properties. The United States Co.'s office building, the mess, bunk and store-houses are nearing completion; to these are being added the residence of the superintendent and the assay office.

NEW MEXICO.

GRANT COUNTY.

In the Carpenter mining district, just across the Black range from Kingston, the Monarch Mining & Development Co. has taken a 90-day bond on the Swartz-Spats group of 17 claims, the company agreeing to spend \$2,500 in development. These properties adjoin the Grandview group, owned by C. T. Barr, of Kingston. — The Enterprise Mining & Milling Co., owners of the Enterprise and Perseverance claims, are building a 100-ton mill. The ore is free-milling and runs from \$15 to \$20 per ton gold.

WYOMING.

CARBON COUNTY.

A 15-ft. vein of copper ore was cut recently in an adit being driven in the property of the Morris Mining Co., near Encampment. The vein was cut at a depth of 150 ft., and 500 ft. from the mouth of the adit. There is also said to be a cross-vein of gold-bearing quartz in this property.

CANADA.

BRITISH COLUMBIA.

The Northport smelter is to be re-opened and operated on ore shipped from Le Roi mine at Rossland, an agreement having been reached between the Le Roi Co. and the Consolidated Mining & Smelting Co. Owing to the discovery of new shoots of high-grade ore in the Centre Star and the War Eagle and a large increase in the quantity of custom ore from outside mines there was no particular necessity for Le Roi ore, but under the circumstances the Consolidated Co. has agreed that the Le Roi may furnish 60,000 tons of ore to the Trail smelter within the next several months at a guaranteed minimum and maximum rate.—Shipments for the week ending August 25 were: Centre Star, 1,950 tons; Le Roi, 2,820; Le Roi No. 2, 450. Total for the week, 5,220, and for the year, 206,613 tons. At the Trail smelter there were received during the week 5,430 tons in addition to that received from the Rossland camp. The following mines sent in shipments: Snowstorm, Larsen, Idaho, 63 tons; Snowshoe, Phoenix, 63 tons; St. Eugene, 41 tons; Iron Mask, Kamloops, 455 tons.—The Boundary mines' shipment for the week ending August 25 was increased over last week's figures, the Idaho mine being on the list for the first time. Shipments were made as follows: To Granby smelter—From Granby mines, 17,944 tons; from Skylark mine, 20 tons. Dominion Copper Co. smelter—From Brooklyn-Stemwinder, 2,763 tons; from Idaho, 330 tons; from Rawhide, 858 tons; from Sunset, 726 tons; from Mountain Rose, 72 tons. To Trail smelter—From Snowshoe, 620 tons. To Nelson smelter—From Emma, 255 tons. Total shipment for week, 23,588 tons. Total shipments for year to date, 795,092 tons. Boundary smelters' treatment for week was: Granby, 15,495 tons; Dominion Copper Co., smelter, 4,749 tons; total for week, 20,244 tons; total for year to date, 790,212 tons.

Personal.

J. H. MACKENZIE starts for Dawson this week.

F. W. BRADLEY is at the Alaska-Treadwell mine.

J. V. N. DORR has returned to Deadwood from Denver.

W. L. AUSTIN has gone to Denver from Clifton, Arizona.

F. L. BOSQUI has been to Tonopah on his return from Denver.

THEODORE J. HOOVER is in New York, on his way to London.

ARTHUR L. WALKER has returned to New York, temporarily.

H. FOSTER BAIN is on his way to the Geological Congress at Mexico City.

FRANK LAWRENCE, of South Australia, is at Idaho Springs, Colorado.

F. H. MINARD, on his return from British Columbia, has gone to New York.

M. F. MURRAY is manager of the Gold Development Co., near Marysville, Utah.

JOHN ROSS, JR., of Sutter Creek, is at the Granite Hill mine, Grants Pass, Oregon.

J. H. G. WOLF is examining the mines of the Tonopah Exploration Co. in Nevada.

EDWARD SAMPLES is manager of the Gold Bar Mining Co., Spokane, Washington.

J. BRUCE MARRIOTT is on his way to Buenos Ayres, to inspect mines in the Argentine.

O. WISER is manager of the Kimberley-Nevada Gold Mining Co., at Kimberley, Nevada.

M. J. CONNELL, formerly of Butte and now living at Los Angeles, visited Monterey this week.

ALLEN H. ROGERS has resigned from the service of the American Smelters Securities Corporation.

J. A. COX, of Colorado, is manager of the Annie Laurie mine in the Gold Mountain district, Nevada.

FRANK L. NASON has returned to West Haven, Conn., from a professional journey to Newfoundland.

W. A. MICHELL is on his way to northwestern Australia, where he is manager of the Balla Balla copper mines.

BERNARD MACDONALD has returned to Guanajuato from an important inspection in western Durango, Mexico.

O. P. ANKENY is superintendent of the Gilt Edge-Maid Mining Co., operating near Deadwood, South Dakota.

ELMER LORING, of Brockton, Mass., is in Breckenridge, Colo., looking over his mining interests in that vicinity.

W. LAWLOR, of Fremont, Neb., has been looking after his mining interests in the Black Hills of South Dakota.

T. J. GRIER, general superintendent of the Homestake mine at Lead, South Dakota, is on his way home from England.

R. R. LUND has been appointed chemist and assayer at the Old Union Mining & Milling Co., of Breckenridge, Colorado.

JOHN A. CRAWFORD has resigned as master mechanic of the Dominion Copper Co.'s smelter at Grand Forks, British Columbia.

W. L. BOWRON has gone to Grass Valley to take charge of the cyanide plant of the New York-Grass Valley Mining Company.

GEORGE A. BAIRD, president of the Western Exploration Co., has returned to Chicago after making an inspection of his Utah mines.

FREDERICK GRUNDY has returned to Los Angeles from examining mines in southern Nevada and he is now in northern California.

N. C. BONNEVIE, general manager of the Denver Ore Testing & Sampling Co., is visiting Alma and Breckenridge on professional business.

HUGH ROSE has been appointed assistant to the superin-

tendent of mining operations (CORTLANDT E. PALMER) of the American Smelters Securities Corporation.

THOS. R. WEBB, formerly with the Gold Pig mine in San Bernardino county, Cal., is now general manager for the Rothschild's Gold & Silver Mining Co. at Argentine, Colorado.

Books Received.

THE CYANIDE PROCESS, by Alfred S. Miller (second edition), has just been issued. This work describes in a general way the methods employed in the operation of the cyanide process, the interfering substances (cyanicides); the chemistry of the process, etc., and brief illustrated descriptions of some of the more important cyanide plants. Sent by the MINING AND SCIENTIFIC PRESS upon receipt of price, \$1. John Wiley & Sons, publishers, New York City; Chapman & Hall, London.

Trade Treatises.

THE DEISTER CONCENTRATOR is fully described and illustrated in a handsome pamphlet issued by the Deister Concentrator Co., of Fort Wayne, Ind. The Deister is a new form of the table type of concentrating machine, and differs materially in construction from other table machines. It is claimed that but one-fifth horsepower is required to operate the machine when running at 320 vibrations per minute.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

STRONTIUM is obtained mostly from its sulphate, celestite. It is used in the preparation of 'red-fire' in pyrotechnics. It is prepared by the electrolysis of the fused chloride.

FREE-MILLING GOLD ORE occurs in California from the outcrop of veins at the surface to a depth of 3,000 ft. or more, in both Nevada and Amador counties, and in the Bendigo field of Australia, at a depth exceeding 4,000 feet.

WHERE mispickel occurs in ore in depth, its presence may usually be detected at the surface by the peculiar yellowish to grayish-green color of arsenic oxide which discolours the ore in the superficial portion of the deposit or vein.

IN a district where veins are irregular in dip, the best way is first to sink a shaft on the vein for prospecting purposes, and when the direction of average dip has been ascertained, a working shaft may be sunk where it will prove most convenient and economical in handling the ore. Shafts sunk on a vein which frequently changes its dip and strike are usually unsatisfactory and increase the cost of mining.

IN Charters Towers district, Queensland, Australia, good timber being scarce and long timbers with difficulty obtainable, the method of support adopted is there known as the 'pig-sty.' The sty is built up as a crib and filled with waste rock, reaching upward to the hanging wall. The ground is heavy and swells on exposure, making timbering additionally expensive on account of frequent necessary repairs.

IN the gold mines of the Kalgoorlie field, Western Australia, the water is not fresh, as in most mines elsewhere. It contains from 6 to 19% solids. That from the Great Boulder, on evaporation, yields sodium chloride, 11.164%; magnesium chloride, 1.425; calcium sulphate, 0.462; lime, 0.4223, a total of 13.473%. The water was formerly sold at the collar of the shaft for \$1.25 to \$1.50 per 1,000 gal. This was before water was piped into the district from Helen river.

AN ORE which carries disseminated lead sulphide (galena), may also contain silver and gold. A careful separation of the lead ore from the gangue and assay of the products of concentration will then determine whether the precious metals are only associated with the lead sulphide or occur in the gangue as well. In some instances the gold is most abundant in the quartz, and the silver is closely associated with the lead, but concentration separates most of the gold from the gangue, collecting it with the lead-silver minerals. In such ore the gold may usually be recovered by amalgamation before concentration.

MOUNT MORGAN, the noted gold mine of Queensland, Australia, is practically a hill of gold-bearing mineral. Originally its summit was about 600 ft. above the Dee river which flows at the base of the hill. The outcrop was a heavy cap of ironstone, the greater portion of which has since been removed. Most of the material beneath the iron cap is silicious kaolin and has a dry, chalky appearance. The great open-cut is dazzlingly white in the sunlight. At depth the rock constituting the ore becomes hard, dense, and dull gray in color, scintillating with the bright particles of iron sulphide.

The original rock-mass is described as felsite, which is intruded in every direction by dikes of diabase.

BARON VON RICHTHOFEN wrote a treatise, entitled, 'A Natural Succession of Volcanic Rocks,' in which he attempted to prove that igneous rocks of the various kinds were ejected, in any particular district, in a regularly successive order, and that these eruptions were not a matter of haphazard occurrence. His conclusions were based largely upon the occurrence of the eruptive rocks in Washoe district, Nevada (Comstock Lode). It has since been shown in widely separated regions of the world that Von Richthofen's theory of geological succession of eruptive rocks is well supported by facts. This valuable contribution to the literature of mining was published as a memoir of the California Academy of Sciences, in 1867.

ANNUAL ASSESSMENT WORK must be done on unpatented mining claims by the owner, or by some one in his employ, or at his instance. Work done by a stranger cannot be credited to annual assessment. It is possible that work done by a friend with the consent of the owner might be properly called assessment work. If there is any likelihood of serious dispute, and the owner is still in possession of the property, the safer way would be to begin at once work and continue it until \$100 worth has been performed. The law is such, that although the claimholder may have done no work for several years, his title is good until some other person appropriates that which the original locator evidently thinks worthless, but the owner having commenced work, no stranger may interfere, and the Government does not require the labor due in past years.

FAULTS have occurred in the rocks of every geological age, and similar processes are operative now. The greater number of earthquakes occurring within historical time has been due to movement of rock-masses on fault-planes. Such was the earthquake occurring on the Pacific Coast of California on April 18, 1906, and that which visited Chile, S. A., on the sixteenth of the present month. The greatest faults known to geologists represent displacements, of rock strata, of many thousands of feet, but none of these great movements were abrupt. In most cases erosion has nearly kept pace with the movement of the rising side, as is well illustrated in the Hurricane fault, crossing the Grand canyon of the Colorado river in Arizona, where in a maximum displacement of 12,000 ft., the rising side has been eroded at a rate which permitted it to gain only 1,000 ft. in elevation over the lower side.

THE simplest form of condenser employed in distilling the salt water in Western Australia was constructed of five cubical tanks of 500 gal. capacity each. These tanks are set on edge to form a boiler 20 ft. long. A similar row is set parallel with the first, with the edges adjoining. These are built in with stone or brick, a fireplace being provided in front between the two lines of tanks, and flues so arranged that the heat after passing beneath the boilers returns to a chimney near the fireplace. The tanks are connected below, while above they lead to a common pipe through which the steam passes. This pipe leads to a closed jacket which surrounds a galvanized iron tank, the tank itself being full of the salt water, which has to be distilled. A portion of the steam generated is condensed to water and drains away to a reservoir. The water in the tank is raised to near the boiling point through its contact with the steam, and runs continuously into the first tanks, or those on each side of the fireplace. The salts in the water, which soon deposit, are blown out at the opposite end of the improvised boiler from time to time.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Copper in Cyanide Solutions.

The Editor:

Sir—I am on my way back to the mines again. Just had a letter from my cyanide man, which says we are getting a fearful lot of copper in the zinc-boxes. Will you send me, to my address at the mine, anything that has been printed of late on this subject, for all I know seems very meagre on the matter.

R. B. S.

New Orleans, August 14, 1906.

The presence of copper in ores causes decomposition or loss of cyanide when they are treated by the cyanide process, especially when it occurs in the form of carbonate, each pound of copper dissolved combining with about four pounds of potassium cyanide. A further trouble is met in the precipitation by means of zinc-shaving, owing to the tendency of the copper to form a firm metallic coating on the surface of the shaving, when the cyanide solutions used are comparatively weak. With stronger solutions less copper is precipitated, and then in a more loose and spongy form, which does not prevent the deposition of gold and silver. The experiments of Von Oettingen (*Journal Chem. & Met. Soc. South Africa*, Feb., 1899, and *Proceedings*, Vol. II, pp. 557-570), and of Christy (*Transactions A. I. M. E.*, Sept. 1899), show that the difference of potential between zinc and copper is greatest in very weak solutions of KCN, becoming very small in strong solutions. This is brought out in a graphic manner in Prof. Christy's Fig. 19. Experiments and working results quoted by Sharwood (*Proceedings 13th Convention California Miners' Assoc'n*, pp. 209, 210, MINING AND SCIENTIFIC PRESS, April 29, May 6 and 13, 1905) show that much more of the copper present was thrown down from weak than from stronger solutions. See also Browne (MINING AND SCIENTIFIC PRESS, Jan. 24, 1903).

Whether it will pay best to use stronger solutions, or to add cyanide before precipitating, or to substitute some other method of treatment or of precipitation, will depend on a number of circumstances. This is discussed by Julian & Smart (*Cyaniding Gold and Silver Ores*, p. 209). The dipping of zinc-shaving in a solution of lead, patented by MacArthur, was intended to overcome the difficulty caused by copper in the zinc-box. Another patented process (Porter's) is said to be used at the Bagdad-Chase mine, the gold being precipitated by zinc shaving and the copper afterward removed by prolonged treatment with zinc-dust and ammonia. This was described in the MINING AND SCIENTIFIC PRESS of May 20, 1905.—EDITOR.

The Flood of Gold.

The Editor:

Sir—Since the annual production of gold has been climbing up beyond the figure of 300 million dollars' worth annually it has become less valuable, as indicated by the rising price of commodities; that is, the purchasing value of money, based upon a gold standard, has been decreasing. As a result of this, labor has demanded a larger money compensation; and, with increasing prosperity, has often secured it; but the habit having been formed by the workingman of demanding more pay, in the future, have to be met by the employer of labor by organization, just as the laborer has employed it to obtain his increased pay. So long as greed exists, either on the part of the employers or employed, conflicts are sure to

result. I recollect some years ago noticing on the rocks adjoining a canyon road of a mining camp a sign painted by some down-trodden agitator and prospector in the words, "Suppress greed or this republic dies." Later on I found the average prospector, coming to our reduction works to obtain assays, was ready with every specious excuse to get his work done without having to pay for it. Indeed, greed is a trait which recognizes no condition of life but is found everywhere, among the highest and lowest. That high wages no better satisfy than low ones is exemplified by a case in my experience in 1884 during prosperous times in Leadville. The local brick-layer, busy on the construction of roasting furnaces, was receiving \$6.50 per day payable every two weeks. Before the two weeks were up these men were owing for their board, having blown in their wages shortly after payday. Dissatisfied with their pay these men went on strike for \$7 per day. One of the walking delegates therefore appeared upon the scene where the brick-layer was busy at the furnace and asked him: "Jim, are you going to work for \$6.50 per day?" "I'm damned if I do" replied Jim, and throwing down his trowel he walked off.

Berkeley, August 9, 1906.

Best Shape for a Shaft.—II.

The Editor:

Sir—Alexander Forsyth favors the 5 by 16 ft. shaft, and considers it well adapted to the probable requirements of the mine in question, but points out the fact that no mention has been made of the character of rock-handling appliances to be used in the shaft. He also suggests the advantage of an auxiliary timber-hoist in a separate compartment, which would permit the exclusive use of the other compartments for the hoisting of ore. He discusses the amount of timber required in shafts of the various shapes that have been proposed, but says he can see no necessity for enlarging the shaft to 10 by 16 ft. The final suggestion of Mr. Forsyth is that the lower portion of the shaft be sunk beneath a bulkhead constructed at some convenient point in the shaft, hoisting being done by an auxiliary engine placed above the bulkhead. This is an excellent idea, and one frequently adopted in deepening shafts in working mines, below levels already opened, which Mr. Forsyth assumes to be the case in this instance. It permits the uninterrupted conduct of mining operations while shaft-sinking is in progress. The waste rock, or ore, is hoisted and automatically dumped into a pocket or bin, from which it may be drawn into cars and distributed where required in stopes for filling, or, if ore, it is drawn into a skip and hoisted to the surface; but if only shaft-sinking is being done, and there are no stopes to fill above, there is no apparent advantage in this extra hoist and additional handling of rock underground. He concludes by truthfully saying: "I believe that local conditions so influence this shaft question that unless the local conditions in two places are first found to be similar, argument from authority is of little avail."

R. V. Norris shows that an attempt to sink a shaft to neat lines is usually impossible, and that although the 5 by 16 ft. shaft contains but 80 cu. ft. to the foot in depth, and the 10 by 10 ft. shaft contains 100 cu. ft. per foot in depth, as it is usually impossible to excavate hard rock to these neat lines, the ratio of any excess of excavation beyond these lines is increasingly in favor of the square shaft. Mr. Norris also thinks that fewer and deeper holes can be employed in breaking ground in a 10 by 10 ft. shaft than in one 5 by 16 ft., and that there would be less shattering of the sides. As a general proposition this is theoretically correct, but the character of the rock to be excavated, its hardness, cleavage, and the direction and amount of dip are important factors in the consideration of this propo-

sition. It must be ascertained by experiment to what depth holes will clear themselves in any particular kind of rock. The necessity of carrying timber close to the bottom of the shaft also influences to some extent the depth of holes and the quantity of dynamite that may be safely used in shaft-sinking. Mr. Norris ingeniously divides the 10 by 10 ft. shaft into two compartments of equal dimensions, placing a timber at one side of the excavation reaching from wall to wall, and another across the centre parallel with the first. These timbers are put in like horizontal stulls; one compartment to be used for pump and ladder-way, the other for two skips

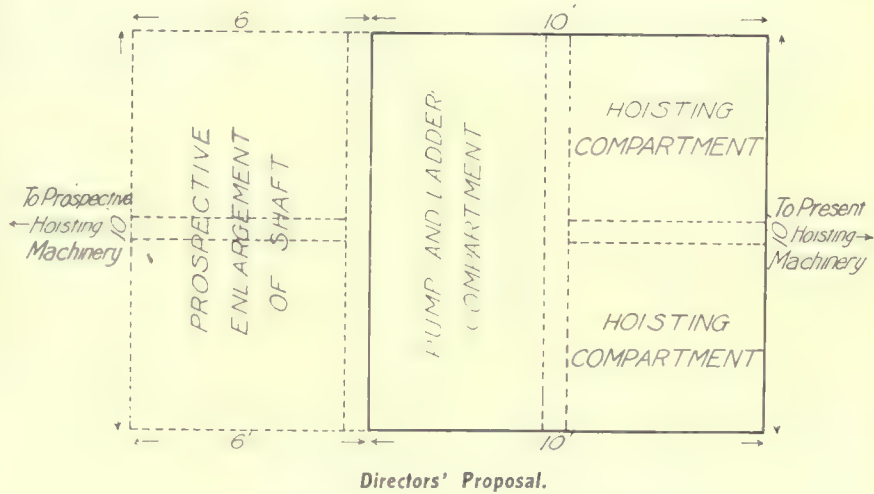

or cages, running in guides. This plan appears entirely feasible, and as the timbers are to be solidly set in hitches they would probably give no trouble after once having been carefully placed. The exact cutting, however, of over 1,500 hitches in hard rock is no small matter. This idea, it seems, might be improved upon by setting the central timber or bunt on a little nearer to one side, allowing a full five-foot width of compartment inside the guides, otherwise the two timbers and guides will take up about 20 in. of the 5 ft. allowed this compartment by Mr. Norris, to which must be added at least two inches for thickness of sides of the skip, draw-bar sides, guide-shoes, and free-running space between guides and shoes, making a total of 22 in., leaving but 3 ft. 2 in. for inside width of skip. If steel I-beams be used in place of timbers, as suggested by myself, the dimensions of which, according to Mr. Thos. H. Leggett, need not exceed four inches in width, then the space occupied by I-beams, guides, etc., may be within 16 in., which would leave 3 ft. 8 in. By shifting the centre bunt on four inches to one side, as previously suggested, a full four feet could be had for interior of skip. This would admit of two skips side by side in this compartment, each having a sectional area 4.5 by 4 ft. A skip of these dimensions, six feet deep, will safely carry five tons of ordinary broken rock, necessitating but 100 trips of each skip to hoist 1,000 tons during 24 hr., which amount may be

easily doubled with proper hoisting machinery. The pump compartment would then be 10 ft. by 4 ft. 8 in., but that compartment should also be provided with a similar steel wall-plate at the opposite side, for support of pump-columns, sinking pump hangers, platforms and ladders.

John Ross, Jr., favors the rectangular 5 by 16 ft. shaft, but believes the shaft should be fully timbered with shaft-sets. His experience has been largely with heavy ground and he considers substantial timbering imperative. He also points out the difficulties in the way of accurately placing shaft-timbers like stulls, and the dangers arising from their getting out of alignment. Mr. Ross also cites an instance where he sunk a shaft 8 by 20 ft., outside dimensions, with an average of 18 holes per round — six for the cut, and a double row of three each at the ends back of the cut. In his opinion the first cost of a shaft should be given less consideration than the cost of operation after the shaft has been completed.

R. Gilman Brown states clearly that in his opinion the 10 by 10 ft. shaft should be utilized, and does not favor changing its shape to 5 by 16 ft. or otherwise, except possibly, to enlarge it to 10 by 12 ft. He also insists that the shaft be provided with end plates and centre-piece, and that these sets be supported by posts to afford the necessary rigidity, binding the sets, and permitting a distribution of any strains taking place to a number of timbers.

Mr. Brown is properly opposed to sinking a deep shaft without using full shaft-sets, owing to the danger of collapse or the fall of individual members, of which there is always danger in any other than the full shaft-sets, where all timbers are inter-dependent, each forming part of a complete system. Where speed in sinking is desired, Mr. Brown thinks the rectangular shaft has the advantage, and says, "ordinarily in an oblong shaft two bars and two machine-drills are in use with two sets of drillers. This results in: an immediate gain of speed; in placing the centre-cut holes to better advantage, and in making possible mucking out one end of the shaft, setting up one machine, and then mucking out the other end, while drilling is in progress. In a 10 by 10 ft. shaft I have not found this method possible; it results in too much crowding for good work." The east shaft of the Kennedy mine, near Jackson, Amador county, Cal., now down vertically nearly 3,000 ft., contains three compartments, each about 5 by 5 ft. It is timbered from top to bottom by an elaborate system, including 'bridges,' which were unnecessary owing to the hard ground. In this shaft three shifts worked, employing four machines on two bars. From 28 to 35 holes, five to six feet deep, constituted a round, requiring usually about 180 ft. of drilling, the rock being hard, tough meta-diabase, metamorphosed diabase-tuff, and diorite. In this formation about three feet were sunk daily. The

timber gang worked on a platform while drilling was in progress below. Whenever the full round of holes was completed, the round was blasted. In anticipation, the muckers, an entirely different set of men, were previously called, no matter at what time, day or night, and went down as soon as the air was clear enough to make it safe to venture below. Usually a few minutes after blasting, the air was better at the bottom than 50 to 100 ft. above it. In this shaft everything was made subservient to speed, no hand-drilling was done at all, all squaring up being done by machines. We know of no shaft sinking accomplished at greater speed through equally hard and tough rock, though in numerous cases the speed of sinking has been greatly exceeded under more favorable conditions.

Carl Henrich summarizes his opinion on the subject by saying, "In deciding on any particular shape for a shaft, it will be advisable to consider, in the first place, what I may call the ultimate maximum duty which the shaft may be called upon to perform, in the way of hoisting rock, water, men, tools, etc.; and in the second place, if two different shapes would serve the same purpose equally well, or approximately so, to give that shape the preference that will afford the best facilities for the work of sinking. And in this last consideration it is the facility and convenience of handling the water, which are of far greater importance than the possible saving of 15 or 20% of mucking. Any blast may bring a sudden and unexpected influx of water." Mr. Henrich is of the opinion that there is not a great difference between a shaft 10 by 10 ft. and one 5 by 16 ft. either in cost or facility of sinking, and says most engineers favor the rectangular shaft, for the reason that shafts of that shape are customary, and the real reason which brought about a discussion was the proposal to make a jog in the shaft at 320 ft. by changing the shape of the shaft from 10 by 10 ft. to 5 by 16 ft. As the jog is not customary, this raised the question, "What is the best shape for a shaft?" In the opinion of Mr. Henrich the only important consideration favoring an oblong shaft is custom, as in his opinion anything that may be done in a 5 by 16 ft. shaft may be done equally well in one 10 by 10 ft., and concludes by remarking that in contemplating the sinking of a shaft, that shape and size should be selected which will best fulfil the requirements of each particular case.

Wilbur E. Sanders is of the opinion that the rectangular shaft is preferable because of its easy construction in the first place, and the facility with which all or any portion of it may be repaired. He suggests, however, that the 10 by 10 ft. shaft may be divided into four compartments by placing across it three 8 by 10 in. buntons, set edgewise with the shaft, and one central buntion crossing these at right angles, and considers that all the requirements mentioned by Mr. Burrows could be met in such a shaft. Mr. Sanders, in a supplementary communication, suggested the ingenious idea of dispensing with the side buntions and securing the guides to the wall by means of U-shaped brackets, the ends to be wedged tightly into holes drilled at the proper place in the walls of the shaft, thus affording two ample hoisting compartments, and two pump and ladder-way compartments. He even suggests, that by this arrangement the 10 by 10 ft. shaft might be reduced in size below 320 ft. and still be large enough for all purposes of the mine under discussion.

Summarizing: the opinion of the several engineers who have contributed to this discussion may be considered as representative of a wide range of practice in deep shaft-sinking, including the Rand, the Pennsylvania coal mines, California, Nevada, Montana, Colorado and other important mining regions. The majority of these engineers favor the oblong shafts, though several admit the possible

utility of the 10 by 10 shaft by the employment of unusual methods of timbering.

One important and interesting feature is the expedient suggested to obviate, as far as possible, the use of timber in this shaft because of its expense. It certainly would be short-sighted economy to sink a vertical shaft to a depth of 2,000 ft. or more without timbering it securely from top to bottom, for without proper timbers and lagging there is a constant menace in the exposed rock-walls. It is not difficult to imagine the result of a mass of rock which may become loosened in some manner in the upper portion of the shaft, falling into the excavation, and unless men are cheaper than timbers no such risk should be taken by any mining company.

W. H. STORMS.

August 4, 1906.

Accidents in Shafts.

The Editor:

Sir—The article in your issue of July 14 on 'How bodies fall in deep vertical shafts' attracted my attention, not from the point of view which it gives, but from the point of how human bodies falling by accident into shafts are found usually stripped of all clothing. It has been my misfortune to have had two such accidents happen in mines under my control, under the following circumstances: One frosty morning at the Rarus mine, in Butte, two top-men stepped onto a water-tank at the surface, and signalled to the engineer for the 40-ft. level, which is actually 112 ft. below. The engineer lowered to about this point, when, to his surprise, he received the same signal, and immediately thereafter the cable on the reel gave a great jerk, and then snapped back, broken, into the engine-house; the two men, with the 1,000-gal. tank, had fallen to the water-level 1,550 ft. below. The tank mushroomed on striking the water, just as a leaden bullet will do on striking a wall; it destroyed the timbering and the pipe-column, so that it was about a week before the bodies were recovered; both were in the tank, and with them all, or nearly all their clothing, including their boots, but the corpses were *stripped naked*. On my expressing my surprise, I was told by the foreman and others that this is the universal result of a human body falling any great distance into a shaft.

The other accident only corroborated this in part. The victim, an Italian miner, had been gambling and had lost all his pay-check; he and his partner were eating their lunch on the station of the 700-ft. level of the mine, when after bewailing his loss, he suddenly jumped to his feet, ran to the shaft, and with a wild yell plunged over the guard-rail, and fell to the sump just below the 1,000-ft. level. His body was at once recovered, it still retained the shirt and overalls, but his boots were found, still tightly laced, beside the bare-footed body. He had fallen a little over 300 ft., and the men declared this was not far enough to complete the stripping process, but to my mind the loss of his shoes is rather a poser, if the other supposition be a true one.

Possibly some of your readers have had similar experience and can add to the evidence for or against the above theory?

JAS. W. NEILL.

Pasadena, Cal., August 14, 1906.

To THE struggle for bare existence, which never ends, though it may be alleviated and partially disguised for a fortunate few, has succeeded the struggle to make existence intelligible and to bring the order of things into harmony with the normal sense of man, which also never ends, but, for the thinking few, becomes keener with every increase of knowledge and with every step towards the realization of a worthy ideal of life.

Mining in Transylvania.

Written for the MINING AND SCIENTIFIC PRESS
By ERNEST LEVY.

Transylvania, or Siebenburgen, is the extreme eastern portion of Austria-Hungary, and is bounded on the west and north by Hungary proper, east by Bukowina and Moldavia, and south by Walachia. It occupies 21,000 square miles surrounded on all sides by mountain chains, whereas the interior is barred and striped with lower ranges. It is only along the courses of the principal

A Roumanian House.

rivers, the Aluta, Maros and Szamos, that plains of any size are found. These mountains, which attain an altitude of 8,340 ft., may be regarded as forming the south-east group of the Carpathian system. The western portion of the mountains of this district, known as the

A Hungarian Stamp-mill.

Erzegebirge, is the ore-bearing country, as its name indicates.

The geology of the Csetras chain of mountains, with which we are chiefly concerned, is quartz andesite or dacite and extends as an interrupted body for six to seven miles in a north and south direction. Of the various rocks associated with the dacite may be mentioned trachytes in various degrees of alteration, containing free-milling gold veins and enclosing large masses of normal sandstone and conglomerate. In the neighborhood of this occurrence is found a cup-shaped deposit of altered trachyte known as greenstone measuring at the surface 3,000 ft. long and 1,800 ft. broad, and in this free-milling gold and gold telluride veins of great value occur; so

numerous are these that they might be classed under the heading of 'stockwerks,' although it has been considered best to mine them individually. Further to the north, intrusions of amphibole, andesite, and melaphyre are much in evidence and play an important part as ore-producing ground. They contain rich fissure veins and appear to be factors in the formation of auriferous and argentiferous brecciated contact masses. The dacite itself may also be credited with the production of profitable veins.

Transylvania abounds in mineral springs of all kinds, more especially such as are saline and chalybeate. Hills largely formed of pure salt are met with here and there,

A Gang of Mine Splinters.

and there are also rich subterranean deposits of salt which in some cases crop out at the surface. Some of the saline springs also yield salt enough to render their evaporation profitable. Coal occurs in considerable abundance, but a superabundance of timber has retarded the exploit-

Porkura, Hungary.

ation of it. Deposits of iron are also found. The forests consist mostly of oak, elm, beech, and ash. River washing has also been a source of livelihood to some of the inhabitants.

In the Erzegebirge, the orebodies occur in different forms, including fissure veins, shear-zones, stockwerks, brecciated contact masses, and beds of auriferous conglomerate. Zinc, copper, lead, silver, and gold constitute the valuable metals, although gold has been the chief attraction. The metals occur in the form of blende, chalcopryrite, tetrahedrite, bornite, galena, silver glance, sylvanite, krennerite, nagyagite, native gold, etc. Evidence of the value of the ores is found in the shape of old dumps,

old mills and old smelters, as well as by exploitation, exploration and ore treatment now in progress.

The age of mining here dates back to Roman times; some of the ancient mines still give employment and profit; others are of much later date. One of the present largest and main producers owes its existence to an accidental discovery of ore by a peasant about 160 years ago, and now has 270 kilometres of workings.

To give an idea of the size and results achieved in some of the properties now being worked, a short consideration of actual figures obtained from two of these will suffice. During the last few years several men of the energetic and go-ahead type have proved that there is considerable gain to be made from many of the low-grade deposits, and there are good chances of many more of these being found. At one time it was considered beneath the dignity of a manager to do more than grace the property with his presence and receive the salutations of all his subordinates. Energy devoted to such adornments as spotless kid gloves and spick and span uniforms is now generally consumed in the more immediate work of real supervision.

As instances of paying mines, the following may be cited:

No. 1. This is a gold mine where the ore is found in veins up to four metres wide. During the twenty years ending 1903, the tonnage has regularly increased each year; simultaneously, the costs have gradually decreased until they have reached a very low figure. Occasionally, specimen ore is found and is treated apart from the rest. During the period under review a total of 1,235,833 tons were stamped. The ore production rose from 5,855 tons in 1884 to 157,803 tons in 1903; costs went down from \$6.90 to \$1.97 per ton.

The tonnage quoted yielded:

Bullion.....	Kilo. 7,403.219
Specimens.....	4,778.239
Concentrate.....	410.549
Total.....	12,592.007
The bullion is 650 fine.	

The average assay-value therefore has been 4.42 dwt. gold and 2.38 dwt. silver per ton. In the year 1902-3, the assay-value was 4.18 dwt. gold-silver bullion, 650 fine, and of this 88% or 3.68 dwt. was saved, leaving a loss of 0.5 dwt. Specimen ore increased the saving per ton by 1.35 dwt. bullion, making a total of 5.03 dwt., equivalent to a value of \$3.41 per ton. The mining cost was \$1.97; the profit was consequently \$1.44 per ton, or a total of \$227,236 for the year. In the year 1903-4 the loss of gold in the tailing has again decreased to a small fraction of a pennyweight.

No. 2. The orebodies are principally contact lodes and true-fissure veins of small width, more or less regular and continuous along the strike as well as dip. In relation to strike, two systems are known; and where these cross there is found a wide brecciated contact-mass carrying good gold ore. Treatment and dressing are accomplished in a 50-stamp mill with amalgamation plates and concentrating tables, treating 150 tons per day.

During the past ten years 322,830 tons have been mined and treated. The ore has varied in value from 8 dwt. gold and 10.8 dwt. silver to 5.8 dwt. gold and 12.2 dwt. silver during the last four years. Probably 7.7 dwt. gold and 11 dwt. silver may be taken as having been the average. The extraction has only attained figures of 63% for the gold and 20.74% for the silver. Costs have varied from \$4.40 in the earlier years to \$2.68 in later ones and averaged during the period under consideration \$2.86, which includes development and preparation, mining and extraction, aerial ropeway (1.2 kilometres), haulage, milling and concentration, and general and realization costs. The average profit per ton has therefore been 67.4c. per ton.

The method of acquiring land is to apply to the Government for prospecting rights over one or more areas (treischurf) which are circular in shape, and comprise 202,887 square metres for gold prospecting and 566,948 sq. m. for other metals. On proving the existence of ore on such an area, a concession may be applied for; this is rectangular in shape and embraces an area of approximately 58,000 sq. m. for gold concessions and 90,000 sq. m. for other metals.

The population of Transylvania is over 2,000,000, the greater number of whom consists of Roumanians and Walachians. Labor is cheap and varies from 0.8 to 2.4 *kronen* (5 *kronen* being equal to one American dollar). A mine-foreman is paid about 120 *kronen* per month. Many nationalities are found among the miners—Roumanians, Germans, Austrians, Hungarians and Italians. The Italians seem to do the best work and the Roumanians the poorest; the last mentioned as a rule are a lazy and unintelligent class who live almost wholly on maize and liberal supplies of a sort of gin made from damsons which saps their intelligence. The lower class population as a whole is priest-ridden; in consequence operations proceed in a satisfactory manner if a little tact be displayed on the part of the managements in regard to the feelings of those who take charge of the men's spiritual welfare.

Owing to the scarcity of employment, the Government is solicitous for the welfare of the workmen. Government schools will provide the more intelligent miners with courses in mathematics and elements of geology, assaying and surveying. A workman's Compensation Act necessitates the laying by of a sum of money equivalent to two per cent of the pay-roll by the owners for the benefit of the employees in cases of distress, and to this may be added a similar sum deducted from the men's wages. Further, an elaborate form of brotherhood has been introduced in certain cases. By the use of miners' permits (certificates filled by the manager of each successive company with which a man has worked) showing the character, length of employment, etc., of the bearer, both master and man share a benefit.

Smelting is performed at Government works. Certain treatment charges are made, but these are intended only to be sufficient to cover the working costs of such treatment, and when the smelters show a profit at the end of the year, this is apportioned between the contributing mine-owners in proportion to the total value of their ore smelted. The railways which intersect the country are also owned by the Government.

IN Chota-Nagpur and Sambhalpur, two provinces of India, diamonds are found in river-beds, from which they are obtained by some of the low-caste tribes. After a rainy season, the Mahanadi river near the town of Sambhalpur becoming low, a large number of these tribes begin to dam the north channel of the river between an island and the bank. Later, when the river gets still lower, the gravel included in this dam is collected and carried to a dry, flat place, where it is washed for gold and diamonds. The quantity of gold obtained is very small, and may be barely enough to pay for the daily meals of one person, but sometimes the washers are rewarded by the find of a good-sized diamond, which may keep a family in ease and comfort for years. The diamonds found in this river-bed have evidently been brought down from a higher source, perhaps from the headwaters of the Mahanadi river, and a thoroughly equipped prospecting expedition possibly would find the matrix bearing the diamonds.

ARGUMENTS concerning the workings of nature usually regard nature as formerly parsimonious of time and prodigal of violence.

Cyanide Practice With the Moore Filter....I.

Written for the MINING AND SCIENTIFIC PRESS
By R. GILMAN BROWN.

The plant, of which the following is a description, was designed, erected and brought to satisfactory operation during the years 1904-5. Much of the burden of the preliminary investigation and construction fell naturally upon the shoulders of Mr. Theodore J. Hoover, superintendent of the company, for which the writer was general manager. During the progress of the work a large mass of data, experimental and practical, was collected, which the two of us had planned to collate and publish in collaboration. This was all lost in the San Francisco fire. This paper and drawings have been prepared, largely from memory, but with the valuable assistance of the private notes of Mr. E. H. Nutter, who from his position as mechanical engineer and later superintendent for the Standard Co., had been fully in touch with the plant from the first.

Ever since the installation, in the early '90s, of the first cyanide plant at the Standard mine, at Bodie, California, under the initiative of Mr. Thos. H. Leggett, the treatment of the slime has been a problem of growing importance. The earliest practical attempt to solve it was in the nature of an evasion; namely, to break the caked slime from the ponds with a disc-harrow and mix it with sand. Apart from the cost, which came to an additional 30c. or more per ton on the whole tonnage, including the sand, the coarse material was only sufficient for the dilution of a portion of the slime product. Besides, this method took no advantage of the fact that by agitation the slime would yield a higher extraction in a shorter period. For want of a better way, the practice was continued for a time, as the only way of preventing the congestion of the tailing ponds with untreatable slime. But active experiments were made in other directions.

Agitation and decantation were discarded because of the flocculent character of much of the slime, that would not settle in 72 hr. to over 15% solids. Filter-pressing was tried and abandoned, because an eighth of an inch of pure slime would make the cloths impervious, even under 120-lb. pressure; and even if the slime was mixed with fine sand, the filtering was so slow that the sand settled out in the chambers, with the same result.

Dehydration of dry slime by roasting made both filtering and decantation possible, but with lower extraction and high cost; moreover, it was not applicable to the direct treatment of the wet product from a stamp-mill. More than one method of filtration in vats during agitation was tried and discarded. In the summer of 1903 the first crude tests with the Moore method were made, with no brilliant results. Later a personal investigation of the plant at Mercur made clear the inherent advantages of the method, while at the same time it exposed certain mechanical deficiencies. An experimental plant of half a ton capacity was installed at Bodie and from the first the results were good. Such was our success that by the middle of the winter we decided to apply it to all the tailing from the Standard mill. In designing the plant every care was taken to avoid the defects of the Mercur plant, but notwithstanding this, several months were consumed, after the plant was nominally completed, in alteration and modification, the major part, let it be noted, being in details outside of the Moore process proper. By the middle of 1905 operations had become fairly regular and the profit for the whole year amounted to more than half the cost of the plant.

The ore consists of quartz, iron oxides and clay, the last coming from the decomposition of feldspar in the country rock. At times this equals 50% of the ore and as an average can be taken at 33½%. The gold is partly

coarse and partly very fine, the latter portion amalgamating badly, to such an extent that at any time fine colors can be panned from below the vanners. The proportion of silver is high, the mill bullion being worth only \$10 to \$12 per ounce. Altogether it is a difficult ore to treat, despite the total absence of all minerals ordinarily classed as deleterious.

In conjunction with the introduction of the Moore method weak cyanide solution was substituted for water in the 20-stamp mill and the grade of the plates was increased from 1½ in. to 2½ in. per foot, in order to cut down the proportion of liquid to keep the plates clear. This steep grade, in conjunction with the hardening effect of the cyanide solution on amalgam, has diminished the extraction by free milling from 60 to 50%. After considerable experiment the strength of cyanide solution was settled at two pounds per ton, and with this at first no trouble was experienced with the plates, but of late the lower ones, where the amalgam lies thinnest, have shown signs of wasting, and some have been renewed. Possibly this can be lessened by using Muntz metal or by carrying a heavier coating of amalgam. Lime, at the rate of 10 lb. per ton, is added to the ore before it goes to the crusher. After passing over vanners, the pulp is raised 63 ft. to the high-level flume for conveyance to the slime-plant, 1,800 ft. away. The elevation is done by four Frenier sand-pumps, in series. The three lower ones, 10 by 54 in., have a lift of 16 ft. 4 in. each; the upper one is 8 by 48 in., and has a lift of 14 ft. The high-level flume is four inches wide and nine inches deep, set on a grade of ¾ in. per ft.; the pulp carries 17 to 19% solids and at this grade it flows freely under all conditions of temperature. A grade of ½ in. was found insufficient, particularly in cold weather; a broader flume was also found to give trouble by accumulations of sand. When received at the slime-plant, the pulp is again raised by a centrifugal pump to the cone-separators. A word regarding the two methods of handling pulp: The Frenier pump, for a regular flow and for lifts within its capacity, is most satisfactory; the consumption of power is nominal and the wear is confined to the stuffing-box at the discharge; however, it requires more attention in operation, particularly in starting or stopping, and a great deal of pains in erecting.

The re-grinding is done in a 5 by 22 ft. trunnion tube-mill of Allis-Chalmers make. The feed is from the underflow of two cone-separators. These are of wood, approximately five feet deep and with 60 deg. slope of side. No extra solution is used to effect the separation, the degree of which, that is to say the proportion of overflow to underflow, being regulated by a simple needle-valve actuated by a screw and hand-wheel from the top. The routine test for separation is to catch the overflow on a 150-mesh screen and raise the needle-valve until no material is held on the screen. The underflow, containing the coarse stuff and a certain proportion of adhering slime, passes to the tube-mill, being mixed with sand and slime from the ponds, automatically fed into the stream. The outflow from the mill is returned to the cones. The mill makes 26 rev. per min. The pebbles are Greenland concretionary flints, the charge being about 12 tons, which fills the mill a short distance above the middle. This charge seems to be the best for grinding and most economical of power, but the difference is not great and the charge can wear to half this quantity with small diminution of grinding. The attempt was early made to use selected pebbles from local glacial drift, but their irregularity prevented free motion, and gave a high wear of liners, with increased power consumption. The insufficient hardness also of the pebbles made them expensive.

The linings originally furnished were of white cast iron, secured in place only by the arch of the shell. They

were a constant source of trouble from dropping, and their life was short. Soft-wood blocks on end, six inches long, were next tried. There was no diminution of the grinding, but besides their short life—of about 10 days—they introduced an unexpected element in excessive foaming of all the solutions. It was assumed that this was due to a saponification of the wood oils by the alkali in the solution. But whatever the cause, it produced an overwhelming mass of suds, overflowing all the launders and covering the vats with 18 in. to 2 ft. of foam. Mountain mahogany was tried next, diminishing this trouble, but with scarcely a longer life. Silix was subsequently used, and for a time answered well, but when partly worn there was continual delay from replacing worn-out blocks. This objection was entirely aside from the delay of four weeks or more demanded for the full setting of the cement that held the lining in place. The continuation of the use of silix meant the addition of a second tube-mill, that is, the duplication of the re-grinding plant.

Finally, the practice settled down to wrought-iron plates for liners. These are $\frac{1}{2}$ in. by 8 in., cut into 7 and 15 ft. lengths and bolted through the shell. Some of the plates of this lining would be worn through in 90 days, but by replacing these the average life came to over 100 days and the duty to 4,800 tons of sand, ground to 200 mesh. The consumption of pebbles was $15\frac{1}{2}$ tons; reducing this to pounds per ton, the lining wear was 2.44 lb. and the pebble consumption 6.47 lb. It seems likely that the wear of lining and pebbles is rather a function of time than of tonnage and in any case it is certain that the rate of wear of lining at least is much affected by the manipulation and proportion of solid in the feed; so that this somewhat anomalous success with the softer lining is probably in a measure due to the increased skill in adjusting the feed to the mill. It is to be noted as a point in favor of the wrought iron that there is little waste, as it can be worn down thin without breaking. Aside from this, the ease of inserting and securing the straps—all of which can be accomplished in 10 hr.—was the determining argument for their final adoption. The power for the mill is approximated as 50 h.p. when running and 100 h.p. at starting. The maximum grinding capacity of the single unit has not been definitely reached, but it is safe to place it at 60 tons of sand per 24 hr. This makes the duty of a horsepower month 36 tons. At normal cost of electric power in California the power cost comes to 17c. per ton; at the Standard mine, which produces its own power, the cost is $5\frac{1}{2}$ c. An interesting comparison can here be made between the cost in power of stamping from $2\frac{1}{2}$ in. size to 30-mesh and grinding from 30-mesh to 200. The consumption of power in the Standard mill of 1,000-lb. stamps is, for stamping alone, 28 h.p. The monthly tonnage is 1,800, so that the duty of one horsepower-month is 64 tons. The reduction of linear size from $2\frac{1}{2}$ in. to 30-mesh is given in the ratio 25:0.025 or 100:1. For the tube-mill the ratio between feed and product is 0.025:0.001 or 25:1. Summarizing: One horsepower in the stamp-mill reduces 64 tons per month at a ratio of 100:1, and in the tube-mill 36 tons, at 25:1. These figures are, for several reasons, far from accurate, but they serve to show in a sketchy fashion the largely increased power cost of fine-grinding. In connection with the recent notes* of Mr. Butters on the necessity of heavy foundations for the tube-mill, it is interesting to note that the foundations at the Standard are piers of heavy timbers, tied and bolted together with heavy angle pieces of $\frac{3}{4}$ by 8 in. flat iron and carefully bedded on mud-sills set in hardpan. Mr. Nutter tells me that after nearly a year's use, these were tested with a transit and found unremoved. As a final comment upon

the tube-mill, it can be said that it has proved itself a highly efficient fine-grinding machine, but that when the whole plant depends upon a single unit, as in this case, any accident to it shuts down the whole plant. This virtually demands the duplicating of the entire tube-mill equipment—for a small plant, a heavy extra capital expense. This led to experiment with a modified pan for fine-grinding. It was found that a single five-foot pan had a capacity of about five tons per 24 hr. and consumed 10 h.p. or from eight to nine pans were required to handle the coarse product of 20 stamps, at a marked increase of power-cost. No determination was made of wear of metal, but judging from experience with grinding concentrate it would be high, and probably the labor of attending to a battery of pans would be large. Altogether for a small plant, so far as this experience goes, three smaller tube-mills, any two of which could do the whole work, would be preferable to pans, and probably cheaper in installation than two large units.

The percent of solids has been increased in the tube-mill discharge to 25%, or perhaps higher, by the addition of material from the ponds. The settling vats, of which there are nine, aggregate a capacity of 21,000 cu. ft.; they are flat-bottomed wooden vats in two sizes of 70 and 80 tons solution capacity, representing 2,200 and 2,550 cu. ft. respectively. On the basis of inflow of 400 cu. ft. per hour, the one size fills in 5.5 hr. and the other in 6.4 hr. While filling they are agitated, then allowed to settle 28 hr. and slowly decanted down to the upper surface of the slime. This occupies eight hours and two more hours are taken to mix and pump out the sludge, a total of about 43 hr. Forty-two per cent of the solution is recovered by decantation. It passes to an additional clarifying tank and then to the gold tanks. The remaining pulp carries from 34 to 40% solids. Returning to the mechanical details of the settling room: the agitators are drags, actuated by a vertical shaft, driven by overhead crown gearing, but stepped on a steel button, running in quicksilver, on the floor of the tank. Above any level at which the heavier pulp can collect, an 8 by 8 in. cross-arm is secured to the shaft and from this the drags hang by links or short chains. The drags are short lengths of 30-lb. T rail; the speed of seven or eight r.p.m. is ample and the power consumption is low. This drag type of agitator is essential, as otherwise the slime packing around the blades would stall the driving gear. After decantation, the pulp is made homogeneous by stirring with the drags and then transferred to the storage or treatment vats by centrifugal pump or air-lift, both devices being used. For decantation there are hinged pipes that are lowered into the vat, after the requisite clearness is attained and that can be kept near the surface so as to draw off the least turbid solution. These discharge through the sides of the vat a short distance above the bottom. The sludge is drawn off through pipes in the bottom.

For many years the New Chum Railway mine has been the deepest on the Bendigo goldfield. Both the New Chum Railway and the Victoria Quartz companies have been sinking to a depth of 4,300 ft., and the other day the Victoria Quartz wrested from the New Chum Railway its distinction of being the deepest mine. The sinking of the New Chum Railway's shaft has been hampered by heavy water, and recent measurements showed that, while that company was down 4,242 ft., the depth of the Victoria Quartz was 4,255 ft.—*Queensland Government Mining Journal*.

THE gold mines of Western Australia have yielded gold to the value of \$323,833,227, and they have paid dividends amounting to \$70,520,910.

*MINING AND SCIENTIFIC PRESS, May 26, 1906.

The Application of the Pohle-Croasdale Process.

Written for the MINING AND SCIENTIFIC PRESS
By O. H. FAIRCHILD.

The Rigby Mining & Reduction Co. has recently put into commission its new plant, at Mayer, Yavapai county, Arizona. This is interesting as the first attempt on a commercial scale to employ the Pohle-Croasdale volatilization process.

The ore is unloaded directly from the railroad car to a steel-covered crusher-floor in the sampler, which is a building 36 by 38 ft., four stories high. From here, it is fed into a Blake crusher. From the crusher, chutes lead into a 62 ft. elevator, which carries the ore to the top of the sampler. Here, all material passes into a 60 in. by 10 ft. hexagonal screen, the undersize passing thence into a double-cut Vezin sampler, which takes one twenty-fifth, the oversize being deposited in a belt-conveyor 16 in. wide by 135 ft., which feeds it to ore-bins, each having a capacity of 150 tons. The oversize from the screen goes to a pair of Allis-Chalmers rolls, where it is crushed, the product going to the elevator that takes the ore from the crusher.

From the bins the ore is taken in a car to a hopper in the dryer-room, which is a building 30 ft. by 56 ft. From

is deposited and from which it is carried to a bin in the mixer-house. This is a building 64 ft. long, 14 ft. wide and 34 ft. high. It contains an iron ore-bin of 30 tons capacity, in which the finished ore from the roll-house is deposited, and a salt-bin of five tons capacity, in which the salt is stored. Under each of these bins is placed a hopper-scale, the one under the ore-bin being capable of weighing four tons; the one under the salt-bin has a capacity of 1,500 lb. On both of these scales are sheet-iron hoppers to receive the product from the bins above them. Running under these hoppers is a 16 in. by 52 ft. belt-conveyor, which rises at an inclination of about 30 deg. and deposits its material in a bin that holds six tons. Underneath this storage-bin is a box-mixer of four tons capacity. Underneath that is a storage-hopper of six tons capacity.

The material for a charge is drawn from the salt and ore-bins, in proportionate amount, into the scale-hoppers, where it is accurately weighed. The valve-gates are then opened and the ore and salt are fed in a stream to the belt-conveyor and deposited in the 6-ton hopper over the mixer. This is a square box made of sheet steel, something after the pattern of a cement-mixer. The mixer is then rotated until the salt and ore have been thoroughly mingled, and is then dumped into the lower 6-ton hop-

The Rigby Reduction Works at Mayer, Arizona.

the hopper the ore is removed by an elevator to the dryers. The smaller of these is 41 in. at the large end by 18 ft. long; the large dryer is 60 in. at the large end by 26 ft. long; it has four compartments, the compartments and shells both being made of wrought iron. The ore is dumped from these dryers into brick bins from which it is drawn into a car on a track sunk eight feet below the floor of the dryer-room, this track running into the lower part of the roll-house, which is 30 ft. by 56 ft., three stories high. The track from the dryer-room runs over the tops of four hoppers, in the bottom of which are screw-feeds actuated by an independent counter-shaft. After the ore is dumped into these hoppers it is fed into the bottoms of four elevators that deliver it to the screens in the top story of the building. The ore which passes the 20-mesh cloth, covering the 50 in. by 8 ft. conical screens, is deposited on a 16 in. by 84 ft. belt-conveyor and carried to an iron pulp-bin in the mixer-house. The oversize goes to three 30 in. by 14 in. rolls and one 20 in. by 13 in. roll, the latter being used largely for crushing salt. After being crushed, it returns to the hoppers which receive the ore from the dryer, whence it goes again to the screens. There is a dust-collecting system of three No. 39 Prinz & Rau machines with their fans and the necessary galvanized pipes which are connected with all dust-producing parts of the machinery, the dust that is collected being deposited directly on the 16 in. belt-conveyor, which takes it to the pulp-bin. The 20 in. by 12 in. roll, which crushes the salt, has an independent bin in which the salt

per ready to go to the furnaces. From this hopper it is taken to the furnace-house in a bottom-dump car. At the feed end of each furnace is a five-ton sheet-iron hopper with a screw-feed in the bottom. This screw-feed furnishes a continuous stream of ore and salt to a pipe running into the furnace. The furnaces are wrought-iron cylinders with half-inch shells, 5 ft. 6 in. diam. at the feed-end and 7 ft. 6 in. inside diam. at the discharge, and 36 ft. long. They are lined with 6 in. of fire-brick and have a series of standard fire-brick projecting three inches beyond the inside surface of the lining. These serve as rabblers. The fire-box is situated at the discharge end of the furnace, while at the feed-end is a smoke-box 4 ft. by 6 ft. clear on the inside. The furnace-room is 132 ft. 8 in. long by 88 ft. wide. Four furnaces are in place, with room for three more. The ore, after treatment, is discharged at the fire-box end into a conveyor that takes it to the waste-dump. From the smoke-box a pipe 4 ft. diam. conducts the fume to the inlet collection-chamber. This is a building 98 ft. long, 30 ft. wide and 30 ft. high, one story; it contains the collection-chambers and flues for cooling the gases coming from the furnaces.

These collection-chambers are of brick, 12 ft. 8 in. long by 5 ft. 2 in. wide, the inlet-chambers being 6 ft. high and the outlet 5 ft. high. Midway between them is a chamber 5 ft. square and 5 ft. high, on which rests the centre portion of the M pipe. The chambers are so built that from the inlet, where the gases are introduced by

the 4-ft. pipe from the furnace they pass through A pipe, which is 20 ft. high to the apex, rising and descending to the outlet-chamber. The gases then return to the inlet through an M pipe of equal height, then passing back from the inlet to the outlet-chamber again through another A pipe. These pipes are of 3 ft. diam. and have a total length of 200 ft.; they are built of sheet steel; they are so constructed and placed that any precipitation of fume falls into the collection-chambers, from which they are removed through suitable doors. From the outlet, the fumes pass through a 20 in. sheet-iron pipe to a Root blower. Passing through this blower, they are forced through a 20 in. pipe into the condensing-chambers. These are in a building 96 ft. long by 44 ft. wide. One half of it is 28 ft. high; the other half, containing the bag-houses, is 40 ft. high. These condensing-chambers are 21 ft. by 16 ft., and are built 6 ft. high of brick. They are plastered on sides and bottom with smooth cement. At the height of six feet from the floor is a sheet-iron floor, which contains apertures for fifty-four 18 in. flannel bags 30 ft. long. The sides of these houses, above the brickwork are built of 2 in. by 6 in. studding and lined with first-class clear flooring. The material obtained in the collection-chambers, condensing-chambers, and bag-houses are taken to the filter-house, where the copper is separated. This filter-house is 30 ft. by 56 ft., 24 ft. high. From here the solution goes to the precipitation-house, which is a building 55 ft. 4 in. wide, 42 ft. long, 23 ft. high. This building contains tanks for the precipitation of the copper, which is the only commercial metal contained in the solution.

The chemical principles upon which the operation of the process is based is the fact that many of the metals can be volatilized when heated in a current of chlorine gas or hydrochloric acid. These ores are crushed dry, mixed with salt, and then subjected to an oxidizing atmosphere of 1,000 deg. C. or above. The chemical equation

shows the necessity of sulphur. The amount of chlorine must, for obvious reasons, exceed the theoretical amount required to chloridize the volatile metals. Consequently the percentage of salt to be added will exceed the theoretical, and must be determined by trial. With an average ore the limits may be placed at from 5 to 12% salt but with higher lead and copper contents, even more will be required to volatilize these metals. The relative amount of salt to sulphur as expressed by the above equation is 10% salt to 2.3% sulphur. In practical tests it was determined that, with sulphur much in excess of 3%, preliminary roasting is needed to remove that excess. Otherwise an unnecessary amount of salt will be consumed. Mr. Stewart Croasdale finds that 50 or 60 min. will volatilize the gold contents of an ore with a furnace temperature of 1,000 deg. C., or above. The gold volatilizes as a chloride or possibly as a double chloride with sodium, but these contents break up soon after leaving the furnace and metallic gold is deposited.

As to the volatilization of silver from its ores, much information is available from the literature of hyposulphite lixiviation which was formerly carried on at various camps in the West and in Mexico. However, as pointed out by Mr. Croasdale, his effort was to volatilize the silver to the highest degree practicable, rather than to prevent it (as the roasting of the ore by Russell's process), and his roasting was done in a highly oxidizing atmosphere. Under the latter conditions the silver volatilizes probably more easily and completely than gold, and the silver sublimate is deposited in the dust-chambers or bags as a chloride or sub-chloride. This sublimate, of course, is insoluble in water or dilute acids, a fact which favors the separation of copper

from the silver and gold products in the final clean-up.

The lead volatilizes readily and the sublimate is found to be a mixture of both the chloride and sulphide salts. The copper contents of the ore also volatilize readily but the time required is usually two or three hours, if a considerable amount of copper is present. The sublimed copper is composed of cupric, cuprous and oxy-chlorides principally. Zinc compounds volatilize very imperfectly, so that 50 to 70% of the original zinc is left in the residue. Arsenic, antimony and bismuth would be expected to follow the lead, silver, etc., but iron, nickel and cobalt, especially the former, should volatilize to a certain extent. The behavior of nickel and cobalt has not been definitely determined, but these elements appear to behave much like zinc.

From the description of the mill it will be noted that the crushing and preparation of the ore is similar to that employed by most dry-crushing plants. The ore is reduced to a 20-mesh product, mixed with salt as described, and fed automatically to the furnaces. From this point the plant consists of units, each one being independent and consisting of a furnace, a set of collecting chambers, and cooling flues, a blower, with its connecting pipes, a condensing-chamber and a bag-house. There is no stack to these furnaces, the draft being caused by the vacuum created by the blowers. All gases are drawn into the condensing-chambers and bag-house. The precipitate or flue-dust is taken to the filter-house and treated in leaching tanks for separation of the copper content, the remaining residue being subsequently refined.

The plant has a capacity at present of 125 tons per day; this can be readily increased, the works having been designed to that purpose.

THE SEISMOGRAPH.—In its simplest form an earthquake indicator might be a tray with notched edges so filled with mercury that a shaking of the earth would cause an overflow in the direction of the movement. In the instrument used by science the pendulum is employed, vertical by some Italians, horizontal by the Japanese, English, most European and American observers. A movement of the earth affects everything but the pendulum, which is so freely hung as to remain stationary, and a recording device makes the result visible. Of old with the vertical pendulum a sharp point drew the profile of the movements on a blackened surface. Photographic paper in moving strips serves the modern instruments. The horizontal pendulum turns on a vertical axis and carries at its extremity a heavy weight which earth shock does not reach. In the Milne seismograph a platinum sheet attached to this weight has a slit intersecting at right angles a slit in a second sheet underneath. In times of quiet reflected light passing through both slits makes one point and prints a straight line on the moving bromide paper. When the earth shakes the lower slit moves and the line becomes crooked, according to the strength of the shock. A clockwork arrangement with shutters and a light times the disturbance. The instruments are so delicate as sometimes to indicate shocks which no men have felt.

The independent oil producers of Texas and Kansas have combined interests for the construction of an eight-inch pipe-line from or near Chanute, Kan., to Port Arthur, by way of Indian Territory, a distance of 650 miles. The steady decline in production of the Texas-Louisiana fields and the rapid increase in demand for the crude oil for refining purposes prompts this project. Kansas and Indian Territory fields are producing a surplus of the grade of refined oils which will supply the independent refiners of Texas and create a market with which to compete with the Standard.

Cyanide Notes.

Written for the MINING AND SCIENTIFIC PRESS
By E. A. H. TAYS.

Successful cyaniding depends on two things: A working knowledge of the process, and common sense. A certain treatment may be successful at one camp and fail at another; in fact, the treatment successful with ore from one level of a mine, may fail with the ore from another level of the same mine. Consequently, to be successful, the cyanider must be ever alert.

Another thing he must bear in mind, and that is, never to despise future possibilities. I call to mind a personal experience. We were treating with fair success, a refractory lot of tailing of high value, and because the mill-tailing was a little poorer than that from the cyanide plant, we ran all of it down the arroyo, as being worthless to us. Five years later, at the same plant, I treated, at a profit, tailing carrying but one-half the values of that which ran into waste five years before.

We all recognize that oxidation of the charge during treatment is desirable in securing high extraction; but, so far, no economical method of obtaining this condition has been devised. I refer to the leaching of ordinary sand charges, for the agitated charges of slime are readily oxidized. It is generally conceded that in a vat charged with sand, when drained, the charge is affected by the oxygen of the atmosphere to a depth of but a foot or two below the surface. From experiments and accidental discoveries, I am led to believe that such charges are affected to, or nearly to, the bottom; time being the only essential.

I call to mind a small plant treating from 800 to 1,000 tons per month, it being an old plant remodeled. The material treated was a tailing from a stamp-mill, consisting of at least 25% clay slime; and, at best, only 80% could be extracted from it. It should have been arranged to separate the slime from the sand, in order to treat each separately, and this could have been done economically; but, as the plant was working to good advantage, it was deemed best to make no change. The treatment was designed to discharge one vat (about 36 tons) per day, and as there were ten vats, each vat was given a ten days' treatment, although the engineer told me, in turning over the plant, that full extraction was made in seven days. After a month or two some experiments were made, and it was found that as good results as could be obtained from the material treated could be obtained in five days; and, of course, after verifying these results, it was decided to double the output, as this increased the running expenses but little.

While we were waiting for extra supplies (two months) the five-day system was installed, and practice upheld the experiments, as long as we had an excess of vat capacity. When everything was ready to double the output, and every vat was put regularly into commission, our extraction dropped off from 6 to 8% and continued low all one month, before the trouble was detected.

The treatment was as follows:

1. Charge vat with sand	8 hours
2. Charge strong solution (0.2%) from below, valve half open, and let soak	14 "
3. Discharge, valve wide open, until solution titrated 0.1%, then charge weak solution (0.1% on top) and let run	12 "
4. Charge allowed to drain	12 "
5. Strong solution charged from above, until vat filled, when valve was opened, and when the escaping solution titrated, 0.1%, weak solution was run on six hours	12 "
6. Charge allowed to drain	18 "
7. Strong solution charged (from above) until full, and left to saturate	6 "
8. Solution drained off and when titrating 0.1%, weak solution was fed on top, feeding and draining at same time	12 "
9. Let drain two hours, when seven tons fresh water were run on from top and charge let drain	18 "
10. Sample and discharge tailing	8 "
Total	120 hours

This treatment gave us good results in five days, during full charge experiments, when we had extra vats;

but when all the vats were put into commission, as already stated, the extraction dropped as much as eight per cent.

In going over the treatment step by step, everything checked up to the ninth step. It was found that while our scheme called for the treatment indicated, when we had vats to spare, the boys let the charge drain (oxidize, in fact), up to within the 14 hours necessary to fill the water-wash and drain dry enough to discharge, the vats remaining dry about four days before the water-wash was run on. This long period of rest allowed the latent reaction of oxidation to develop fully, and when the water was run on it readily took into solution the dissolved metals still in the tailing.

After this discovery, the treatment was modified, as follows:

1. Charge vats with material	10 hours
2. Charge strong solution (0.2%) from below at one-half valve capacity, and let soak	14 "
3. Discharge solution, valve wide open, and at end of second hour, feed (on top) weak solution (0.1%) valve half open	12 "
4. Let charge drain, valve wide open	12 "
5. Charge strong solution from top, and let soak	6 "
6. Discharge, valve wide open, and at end of second hour, charge (on top) weak solution; valve half open	12 "
7. Let charge drain	18 "
8. Charge weak solution from top, valve wide open, and let soak	6 "
9. Let charge drain, and oxidize	62 "
10. Charge fresh water from top, until vat fills, and let soak	3 "
11. Open valve wide, letting charge drain; this wash going to storage-vat leading to zinc-boxes	13 "
12. Sample, and discharge tailing	12 "
Total	180 hours

This treatment gave good normal results; and, as a charge was run through in 7½ days, it still gave us a total of 1,500 tons per month, instead of 1,000 tons under former treatment.

I firmly believe now that oxidation takes place clear to the bottom of a vat full of sand, the vat having been filled with water and this then allowed to drain off, from the bottom. When full of water, the interstices are occupied by the water, the sand settling and packing as close as possible. As the water drains off, these interstices empty and form a vacuum, which naturally fills with air; the pressure of this being ample to fill the lower voids, as the water recedes. Once the interstices are filled with air, the chemical reactions that take place cause a practical oxidation to set in, if time be allowed; and it is probable that 80% of this reaction takes place within 60 hours. That the interstices in the charge do fill with air is proved by the fact that in running water on to a charge, much ebullition takes place, and for half an hour or more after the charge is covered with water; many air-holes forming all over the top of the charge.

Another proof that chemical reaction takes place in a charge treated as outlined, and then left to drain three or four days, is (from my own tests) that if a water-wash be run through immediately, it will show but a few cents per ton; whereas, if the water-wash be run through several days after the charge has been allowed to drain, it will carry from \$1.50 to \$2 per ton.

Several years ago I discovered that newly turned zinc, if the shavings where stored were exposed to air, was necessary for perfect precipitation. Later, I have learned that solutions running through the zinc-boxes should not be too strong in cyanide, if a product high in the precious metals be desired. When the solutions run 0.1% or over, the reaction set up is so violent, that a larger proportion of zinc is destroyed (oxidized) than is necessary; the resulting slime (auro-cyanide) being low in gold and silver and high in zinc.

With weak solutions the reaction is normal, and metallic zinc is destroyed in proportion to the values in the solution; and the resultant slime is high grade. I have secured slime running \$30,000 per ton and high in zinc, requiring acid treatment; whereas, the next month, on the same grade of ore, slime, low in zinc, requiring no

acid treatment, and carrying \$57,000 gold per ton, was obtained, simply by not allowing the solutions to get beyond a certain strength, say, 0.05%. For this reason, my practice has been, of late years, to run all solutions and water-washes into a common vat, the mixed solutions from which are run to the zinc-boxes. When the solution is above 0.05% in cyanide, it can be run through

Flood-gate. Presa de Los Santos.

the zinc-boxes a little slower; and when below 0.05%, a little faster, to obtain the normal results. Should the solution be very low in cyanide, say 0.01%, and yet rich in metals, a little cyanide can be added to the head box

tion until returned to the boxes. This prevents the violent oxidation that sets in under exposure to the atmosphere.

Architecture in Mining.

In the United States as well as in most other Anglo-Saxon countries, the suggestion of architectural adornment in connection with mine or mill-construction, only provokes derision. Our rigorous attachment to strict utility generally impels us to avoid anything that approaches adornment, leading us to model our mine and mill-buildings in studied ugliness, with outlines rarely pleasing to the eye, and often even repellant. It may not be out of place, therefore, to insinuate that a thought be occasionally given to making our mine and mill-buildings good to look at, instead of allowing them to be blots upon the face of nature.

The Mexican miners carried this idea to extremity in the other direction, as may be seen from the accompanying photographs of a mill-dam near Guanajuato, the summit of which is crowned with statues, the figures representing saints after whom the builders' children were named. This dam, called *La Presa de Los Santos*, or dam of the saints, was built in the 18th century, a tablet in the face of the construction setting forth its completion in the year 1788. Its purpose was to impound water for a *hacienda de beneficio* or mill using the *patio* process, which is still running, enjoying the distinction of being the only one in the district that has retained the old metallurgy.

Around the mines the adornment was often studied and elaborate, the retaining walls were strengthened with arched buttresses, ornamented with scrolls; the entrance to the yard consisting of a beautifully carved archway, the arch surmounted with a statue of the guardian saint, the entire edifice looking more like some old-world religious structure than anything so practical as a mine.

ONE of the recent purposes for which aluminum has been employed is in the making of grindstones, on account

Back View of La Presa de Los Santos.

in each row, if it is found that solutions of 0.01% strength do not precipitate normally.

In the clean-up it is good practice to return all zinc, staying on a 40-mesh screen, to the precipitating-boxes. This zinc should be kept covered with a weak KCy solu-

tion of the property which it possesses of forming under the whetting action a very fine mass which adheres strongly to steel. An examination under the microscope shows the edge of the steel to be perfectly uniform and unbroken, which is not the case when steel is sharpened on stone.

The Estimation of Copper in Ore and Matte.

Written for the MINING AND SCIENTIFIC PRESS
By O. H. PACKER.

Of the several well-known methods for quantitative copper analysis, the electrolytic method is undoubtedly the most accurate and will always be used for strictly high-grade work; but I find that assayers are not, as a rule, sufficiently experienced in the chemistry of electrolysis to make a success of it on all varieties of copper ore.

In order to obtain proper results by the electrolytic method, due regard must be paid to the following points:

1. A uniform voltage should be maintained throughout the determination.
2. Too high a voltage will deposit spongy copper, and zinc will be deposited if present above three per cent.
3. Stop the current when all copper is deposited and not before.
4. If the solution be too strongly acidified some copper will remain indefinitely in the solution.
5. Sulphuric acid has a tendency to deposit spongy copper, especially if much of it be present.
6. Bismuth, lead, and arsenic will be deposited with the copper.

It is evident, therefore, that the assayer must know the mineral constituents of his ore, the approximate amount of copper present and be able to remove objectionable elements. This is requiring too much of the average assayer.

The 'iodide method' is excellent, but it works satisfactorily only in the hands of fairly skilled chemists; besides, it offers no appreciable advantages over the easier method explained in detail later. In the old cyanide method (Mohr and Parkes) the ore is dissolved with acid and enough ammonia hydrate added to produce the blue color, and the solution is then titrated with a standard solution of potassium cyanide. By this plan some time is saved, by not separating the copper from the residue of ore and other metals in solution, but the results are not satisfactory, accuracy being impossible with miscellaneous ores of copper.

The 'aluminum-strip-cyanide method' is, in my opinion, the most satisfactory known at the present time for determining copper at the mine or smelter. The rules to be observed in order to secure uniform and accurate results are few and easily followed. The chief objection to this method is that, in different hands, uniformly higher or lower results will often be obtained owing to variations in manipulation practiced by different persons. Some of the variations which affect results are:

1. High temperature of solution when titrating lowers the result.
2. Large amounts of ammonia added produce higher results.
3. Large amounts of ammonia and acid added will also produce higher results.
4. The amount of copper, acid, and ammonia being the same, the more dilute the solution is, the lower will be the results.

Now, these variations in results have a tendency to neutralize each other; so that unless the chemist goes to extremes, uniform and accurate results will be obtained, especially if the precautions given later be observed.

This method is dependent upon the following chemical reaction:

The atom of copper in the molecule of copper sulphate weighs 63 microeriths and the four molecules of potassium cyanide weigh 260.4 microeriths. $[4(39.1 + 12 + 14) = 260.4]$. By proportion,
63 m.e. : 260.4 m.e. :: 1 gram of Cu. : x grams of KCN
 $x = 4.1$ grams of KCN.

It is evident, therefore, that if a solution of potassium cyanide be made to contain 4.1 grams of KCN to each 100 c.c. of solution and one gram of ore be taken for analysis, each cubic centimetre of potassium cyanide solution required in titration will represent 1% of copper in the ore.

As chemically pure KCN cannot be purchased in the market it is necessary for us to use the commercial article (about 98% KCN) and standardize our solution by titrating a solution of a weighed amount of chemically pure copper. The details of the various operations are as follows:

STANDARD COPPER SOLUTION.

1. Wash a little over one gram of chemically pure copper in hot moderately concentrated nitric acid. Wash several times in distilled water and finally with a little alcohol, though the alcohol wash is not absolutely necessary. Dry very slowly to prevent a coating of copper oxide.
2. Weigh out *exactly* one gram and dissolve in 25 c.c. C. P. nitric acid. Use a tall beaker and cover with a watch glass to prevent the spray falling outside (a frequent source of loss). Heat may be used.
3. Wash the solution into a litre flask and dilute to exactly one litre (= 1000 c.c.) using cold (63° F.) *distilled* water. Precaution: Do not add ammonia or any more water in *any* case. This is your *standard* and *nothing* must be added before trial samples are measured in the (dry) graduated cylinder, beaker, or burette as described later. It may be kept indefinitely for future use.

STANDARD POTASSIUM CYANIDE SOLUTION.

1. Dissolve about 42 grams of the best commercial KCN in about one litre of distilled water.
2. Decant or filter out the sediment and puss, and place in a light-proof bottle for future use. It will keep several weeks but must re-standardize very often—every day likely.

STANDARDIZING THE KCN SOLUTION.

1. Take two 100 c.c. burettes. Wash one (A) out with the standard copper solution (not with water) and the other (B) with the KCN solution (not with water). Discard washings.
2. Fill the (A) burette with standard copper solution and run off to the zero mark. A graduated cylinder will do, but the burette is better.
3. Fill the (B) burette with the standard KCN solution.
4. Run the 100 c.c. standard copper solution into a beaker and add just enough NH_4OH to produce a deep blue color, no more, say, 5 c.c.
5. Begin titrating by adding about 7 or 8 c.c. of standard KCN at once, then continue by adding only a drop at a time, carefully stirring the copper solution all the time to insure a thorough admixture, until the blue color disappears and a pink color appears. A white background will assist in determining the end reaction. Note the number c.c. KCN used.
6. Try several lots of the copper solution to check results.
7. As we took 100 c.c. of the copper solution, containing one-tenth of a gram of copper, for each titration it should require 10 c.c. standard KCN solution but if your KCN solution is too strong it will take less and if weak it will take more. Whatever it takes, multiply by 10 to find out how many c.c. KCN would react on one gram of copper (= 1000 c.c. of standard copper solution) and mark this number on the KCN bottle for future use.

PREPARING THE ORE SAMPLE.

1. Pulverize a dry sample of copper ore to about 80 (or 100 mesh, if difficult ore to dissolve) and weigh out

exactly one gram, using a good balance—not pulp balances.

2. Place sample in a deep evaporating dish on a sand-bath and add 10 to 15 c.c. strong HCl. Cover with an inverted funnel, the stem of which has been broken off. The funnel must fit *inside* of the evaporating dish. After boiling add from 1 to 10 c.c. HNO₃—the larger amount for ores that decompose with difficulty. Boil to one half or one third the original bulk and add about 10 c.c. strong H₂SO₄.

3. Evaporate till *very copious* white, choking fumes arise—not to complete dryness, or insoluble basic salts will form, in which case more H₂SO₄ must be added.

4. Cool thoroughly.

5. Add 50 or 60 c.c. of water and filter (and wash filter) into a tall beaker and place upon a wire-gauze over a bunsen flame.

6. Add a warped strip of metallic aluminum about 2 by 1 by $\frac{1}{8}$ in. size.

7. Boil (actual ebullition) for five minutes. This will precipitate all the copper. If cadmium be present stop, boiling as soon as the solution clears, for cadmium is not precipitated till after the copper. This is the only metal except gold that will be present to affect results. Ore carrying 62 oz. gold to the ton will consume one cubic centimetre standard KCN solution.

8. Immediately decant through a filter, keeping as much of the precipitated copper in the beaker as possible. Wash the precipitated copper several times with distilled water. Discard filtrate and washings.

9. Place the aluminum strip on the filter paper and dissolve off the adhering copper with strong HNO₃, using as little as possible and having the beaker containing the precipitated copper beneath the funnel. Then add enough HNO₃ to the beaker to complete the solution of the copper and then wash the filter paper till free from Cu(NO₃)₂.

10. Dilute the solution by adding 10 c.c. water for each estimated per cent of copper present, judging roughly.

11. Cool to 63° F.

12. Add just enough NH₄OH to produce a deep blue and begin titrating.

If there is a heavy precipitate of aluminum do not filter it out till very near the end reaction—when the blue first begins to fade is a good time.

13. Finish the titration to the same shade of pink obtained in titrating the standard copper solution.

14. The percentage of copper in the sample is formed by a simple proportion. An example will illustrate: Suppose that, by repeated trials on 100 c.c. standard copper solution, we find the average amount of KCN solution required to be 9.4 c.c. (= 94 c.c. on 1000 c.c.) and that a one-gram sample of ore required 31 c.c. standard KCN. Then

$$\begin{aligned} 94 \text{ c.c.} : 100 &:: 31 \text{ c.c.} : x \\ x &= \frac{100 \times 31}{94} = 32.9\% \text{ copper.} \end{aligned}$$

Another example: Suppose 100 c.c. standard copper required 10.2 c.c. standard KCN and that a two-gram sample of ore required 15.2 c.c. KCN. Then

$$\begin{aligned} 102 \text{ c.c.} : 100 &:: \frac{15.2}{2} : x \\ x &= \frac{100 \times 15.2}{102 \times 2} = 7.5\% \text{ copper.} \end{aligned}$$

Various ores require different treatment to bring them into solution. Some ores yield to HCl or HNO₃ alone. Never add H₂SO₄ at the same time; the former acids are added as H₂SO₄ decomposes and expels these weaker acids before they have done their work upon the ore.

I will digress to suggest that the practice of using a

float in a burette can be greatly improved upon with fairly clear solutions. Use the enameled back burette. If one can not be purchased draw an *india ink* line wide in the centre of a strip of white paper and paste the paper upon the back of a plain burette with shellac and coat with the same to make it waterproof. By reflection, the surface of the standard solution shows a black point indicating the c.c. mark on the burette.

Endeavor to titrate the ore sample under the same conditions as to acid, bulk, temperature, etc., and follow the details given *implicitly* before finding fault with the method. Duplicate samples will agree within less than one tenth of a cubic centimetre. Take one gram sample for ordinary ore, two grams for low-grade ore and half a gram for copper matte.

Minute details have been given to enable the careful assayer, though not a chemist, to do satisfactory work.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

The rock from Thompson, Mont., marked B. W. J., is Aplite, a fine-grained mixture of quartz and feldspar—a micaless granite.

The mica from Cobalt, Ont., is fairly good in quality, but will, perhaps, improve somewhat with greater depth. Systems of parallel lines are observed crossing each other in this mica, which is to its detriment. These lines are caused by microscopic inclusions of some foreign mineral, probably tourmaline. Usually some parts of the vein contain mica of this kind, while in other portions it will be absent.

The rock from Alleghany, Cal., marked W. S. H., is Quartz with a little talc-schist adhering to one side. The bright metallic mineral is pyrite, and the white scale, that so easily crumbles to powder, is calcium carbonate that has deposited from infiltrating water. A few scales of a white, silvery mineral, are also observed. These are the secondary mica, magarodite, derived from alteration of feldspar of the wall-rock. The rock is probably gold-bearing.

The rock from Eureka, Nevada, marked T. P., is an inferior black marble (calcium-carbonate). It contains disseminated pyrite, and limonite due to alteration of the pyrite. It may be gold-bearing.

SINCE the expiration on November 29, 1905, of the patent rights on the cyanide process held by the Victorian Government, more attention is being paid to the tailing heaps on the goldfields, and small cyanide plants have increased in number. The Government purchased the patents on February 19, 1900, and in order to recoup itself the purchase money, it charged 2½% on the yield of gold. The cyanide process is now free to everybody. The number of plants in the State has increased to about 200, and likewise the number of men employed proportionately.

GRAPHITE-BEARING SCHISTS are of widespread occurrence in the Central Alps, but they are rarely rich enough to constitute deposits of economic importance. In these deposits the carbon that has assumed the form of graphite is a primary rock constituent of undoubted organic origin. It is not assumed that the coal was transformed slowly into graphite, but that the process was quickened by the high temperature of the granitic magma.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

ENGINE FOR ROCK-DRILLING MACHINES.—No. 826,456; Cassius M. Walker, Pueblo, Colorado.

The combination with the cylinder of a rock-drilling machine and with its ports and tapering valve-socket closed at each end, of a tapering valve fitted to said socket, provided with two heads and an intervening web, the ports communicating with the space between the heads, a chamber beyond the larger head of the valve, a port in said head, a socket in the smaller head with separated shoulders below the same, and an arm with a head fitted to said socket and extending between the shoulders to have a limited motion independently of the valve for rocking the latter.

PULVERIZING MACHINE.—No. 826,062; George L. Pratt, Atlanta, Georgia.

In a pulverizing machine, a pan for the material to be pulverized, having its bottom formed as a convex screen, projecting upward into the interior of the pan, and pulverizing members disposed within the pan.

WELL-DRILLING CABLE.—No. 826,063; Joseph Reid, Oil City, Pennsylvania.

A composite rope having the end of its steel rope wound or bound, and the strands of its hemp rope laid about said steel rope by twisting and winding, and secured thereon by a clamping-rivet passing diametrically through both ropes just above the binding on the steel rope.

CRUSHING-ROLLS.—No. 826,140; Walter G. Bryant, Cartersville, Missouri.

In a crushing-mill, a frame including a pair of longitudinal sills, rigid pillow-box bases carried thereby, a roll journaled in said pillow-box bases, a flanged guide-bar carried by each sill and having a recessed upper face, wear-strips seated in the recesses, slidable pillow-box bases mounted on said guide-bars and having inturned flanged portions embracing the same, said slidable pillow-box bases being also recessed, wear-

strips arranged in the recesses of the slidable pillow-box bases and bearing against the corresponding strips of the guide-bars, a roller journaled in the slidable pillow-box bases, and springs engaging said slidable pillow-box bases and tending to force the rolls into engagement.

HOISTING-ENGINE.—No. 826,956; Sven T. Nelson, Chicago, Illinois.

In hoisting-engines, the combination of engine-controlling mechanism; a brake and means driven by the engine for automatically and successively operating said controlling mechanism and said brake.

ROCK-DRILL.—No. 826,108; James Mathers, San Francisco, California.

In a rock-drill, means for supplying water to the drill-hole, said means consisting of a pipe, a drill-shank having a channel within which the pipe is fitted, a socket member at the head of the shank, a chuck into which the drill-shank and socket member are inserted, a pipe upon which the chuck is slidable, said pipe being in open communication with the socket member and the pipe which is fitted to the drill-shank, and means for supplying water to the pipe upon which the chuck is slidable.

The Iler Hammer-Drill.

We herewith illustrate the Iler Hammer Rock-Drill, which is somewhat different from other hammer-drills. The weight of the drill itself is from 15 to 30 lb., and is easily handled, and can be pointed and operated readily for side, down or upper holes without the use of column. As a convenience and advantage, however, a stoping bar, weighing but 11 lb., made of bicycle tubing lined with brass, is furnished; this enables the workman to keep the machine in constant operation and do more work proportionately. A peculiar and meritorious feature of this drill is in the complete rotary movement or revolution of the bit. The bits are of four-point pattern, and even if one or more points

break in operation, the operator is enabled to continue driving a round and straight hole, because of the complete and continuous rotation of even the broken points. Besides the rotary merit it is well to remark that the drill, being mounted on a brace or crank, for the means of rotation, the operator is given the advantage of the leverage from the crank, while the butt serves as a throttle, swivel, and cushion. In the operation of a 15-lb machine of 2½-in. stroke, 12½ cu. ft. of air under a pressure of from 70 to 110 lb. is required, and for one of 30 lb., with 6-in. stroke, 30 cu. ft. of air. Delivery of air to the drill is made through a tube to the interior of the barrel, as in the case with other air-hammer drills. Already over 200 of these machines are in use at Cripple Creek and in other mining districts in the United States. The machines are being manufactured by the Iler Rock Drill Mfg. Co. at Denver. This company is also manufacturing a valveless type of drill, which is meeting the demands of the trade for a less expensive machine.

Commercial Paragraphs.

ALLIS-CHALMERS Co. announce that its Denver office has been removed to the McPhee Bdg., 17th and Glenarm St., and the El Paso office to the Guarantee Trust Bdg., rooms 301-306. The Boston office is at 50 Congress Street.

SHIRLEY & GRANT, of Reno, Nev., have entered into a contract with the Traylor Engineering Co., of New York, whereby they have become the sole representatives of that thriving New York concern for the entire State of Nevada.

THE BUFFALO STEAM PUMP Co., of Buffalo, N. Y., recently installed a large pumping plant for the McBryde Co. of the Hawaiian Islands. The pumps are electrically operated and were required to prove a very high efficiency by actual test.

THE ELSPASS ENGINEERING & MINING MACHINERY Co., J. H. Elspass, manager, has opened offices at 1650 Champa St., on the ground floor of the Boston Bdg., Denver, Colo. L. S. Pierce, manufacturer of the Pierce Amalgamator, will also have his office at this address, removing from 1653 Welton street.

THE C. H. SHAW PNEUMATIC TOOL Co. recently received a telegraphic order from Walter Douglas, general manager of the Copper Queen Con. Mining Co. at Bisbee, Arizona, for fifty Shaw's Eclipse Air-Hammer Rock Drills. This is claimed to be the largest single drill order ever placed by one man in the United States.

THE DOUGLAS COPPER Co. has just placed with the INGERSOLL-RAND Co. an order for a cross-compound, high-speed, two-stage air-compressor, having a capacity of 3,700 cu. ft. of free air per minute. This is one of the largest compressors on the west coast of Mexico, and is to be erected at the No. 1 shaft of their El Cobre prop-

erty in Sonora, Mexico. There is also to be installed a second battery of boilers and condensing machinery. This, together with the 250-h.p. hoist built for them by the RISDON IRON WORKS of San Francisco, and which went into commission in June, makes the surface equipment at this shaft ample and up-to-date in every respect. Theodore Douglas is now on his way West to close a contract on the Pacific coast for the building of five 110 h.p. traction engines and twenty-five 20-ton ore-trucks to operate between El Cobre and the smelter.

THE ALLIS-CHALMERS Co.—A mammoth gold dredge for service on the Forty Mile district of the Yukon Territory was built this summer at White Horse and floated down the river to its destination. The timbers and machinery for this dredge were dispatched north from Vancouver, and the work of assembling it at White Horse commenced early in the season, so that the completed dredge was started down the river as soon as possible after the ice went out. The mechanical equipment was ordered by the Forty Mile Gold Dredging Co., of Toronto, Canada, through the Canadian representatives of the Allis-Chalmers Co., of Milwaukee. The dredge equipment, which was furnished complete by Allis-Chalmers Co., is special in nature and adapted to the particularly heavy service of the Forty Mile. The dredge proper will be equipped with 5½ cu. ft. buckets. The accessory machinery, ready for operation, was shipped from the various works of the Allis-Chalmers Co. It consists of engines, pumps, boilers, concentrating machinery and a small electric-light plant.

THE LINK-BELT Co. succeeds the Link-Belt Machinery Co., of Chicago, which was organized in 1880 for the purpose of manufacturing labor-saving appliances, employing the product of the Ewart Mfg. Co., of Indianapolis. In 1882 a branch office was established in New York. In 1888 this department had grown to such an extent that it became necessary to have a manufacturing plant located in the East, and in that year the Link-Belt Engineering Co., of Philadelphia, was organized. At no time have the three companies been competitors; the Ewart Mfg. Co. continuing as manufacturers of chain, while the two Link-Belt Companies have operated along exactly similar lines, each in its own territory. The present consolidation was effected by the Link-Belt Machinery Co., of Chicago, purchasing the plants and assets of the Ewart Mfg. Co., of Indianapolis, and the Link-Belt Engineering Co., of Philadelphia. The new company controls three splendidly equipped plants located at Chicago, Indianapolis, and Philadelphia, and the line of manufacture covers the entire line of conveying, elevating, and transmission machinery, malleable and machine-made driving chains.

Publications Received.

THE PRODUCTION OF QUICKSILVER, of Gypsum and Gypsum products; and of Mineral Waters in the United States in 1905, being advance sheets of the mineral resources of the United States for 1905.

THE preparation of ores for dressing by hydraulic classification seems to be the stumbling block of many millmen. Its principle is acknowledged as being the most economical, but the operation and results are far from satisfactory. If we feed crushed ore into a column through which is passing a well-regulated upward current, such particles as are of sufficient weight will fall through the current, while those too light will be held at the top of the column; but if the fine in suspension is not removed from position directly over the column, it will remain there only until a sufficient quantity or weight is accumulated and then drop in a body through the current which rejected the particles individually but which lost its power through their accumulation. Thus it will be seen that a most perfectly designed sorting column would not perform the work expected of it unless combined with a method of carrying away such fine as it would reject. The settling arrangement can be of different forms, but it must bring all ore particles in contact with the hydraulic current, and simplicity of design, with positive operation, is the principal necessity.

Editorial.

THE MACHINERY FIRMS of San Francisco have shown remarkable recuperative power, overcoming the effects of the disaster of April 18 with an indomitable spirit. Among them we venture to mention the Fulton Iron Works, which was reported in the daily press as having been destroyed by fire a second time a week ago. We are informed—and it gives us pleasure to state—that the fire reached only a portion of the foundry and will cause not more than a delay of a week in making castings. We congratulate our friends.

THE QUESTION, 'Who is a Mining Engineer?' is answered by a veteran whose name we are asked not to divulge. We have received several other letters on the same subject, and it is evident that the engineer who hid his fame under the *nom de guerre* of 'Viator' has started a buzzing which may or may not indicate a hornet's nest. The subject is one on which each of us could say something and we anticipate a lively, and possibly useful, discussion. Let it be polite, though penetrating.

THE LAGRANGE MINE in Siskiyou county is, we believe, the largest hydraulic mine in operation in California, for it delivers its tailing into a river system free from the legal restrictions that almost killed hydraulic mining in this State. Another large mine of the same class is that at Cherokee, which is described in detail by Mr. D'Arcy Weatherbe. It affords a good example of this kind of mining and the writer has treated his subject in a manner likely to prove instructive, as well as interesting.

THE GERMAN EMPEROR has given his personal approval to the art of 'dowsing'—that is, the use of the divining rod or forked stick for finding hidden springs, veins of ore, and buried treasure. President Roosevelt has come out as an official and officious advocate of spelling reform. If one of the great irrepressibles passes upon the use of the hazel twig and the other on spelling, why should not one or the other of them pose as an authority on ladies' hats and babies' food? Let the shoemaker stick to his last, and other people to their proper business.

A LESSON may be conveyed in a parable and a moral by a story. Mr. Theodore F. Van Wagenen's recital of the experience of an Australian miner in Rhodesia is excellent, even without its deeper purpose. When an American engineer can write sympathetically in behalf of an Australian miner in Africa, we have a conjunction of interest that is eloquent of the cosmopolitan character of the industry involved. Mining laws are open to destructive criticism and most of us would like to have the laws we have not got; many Americans prefer the simple Australian regulations to their own apex law with its

interminable litigation; others may like the directness of the Mexican 'denouncement' and concession; Australians complain of the lack of protection on the dip when a vein cannot be followed beyond vertical side-lines, and there must be some Mexicans who would like to have a little litigation with their neighbors. All the regulations and laws are misfits at some time or place, because Nature has an endless versatility, making no two lodes exactly alike.

The Power of Public Opinion.

The strike on the street railroads of San Francisco ends as we go to press. It lasted eleven days, just long enough to emphasize the fact that public opinion, if crystallized into expression, is the most effective weapon for stopping unreasonable conflicts between the employer and the employed. San Francisco had bowed her head to those mysterious forces which are legally known as acts of God, but she was in no mood to suffer the folly of those who lightly interfered with the work of re-building and restoration. The average citizen, like Mercutio, exclaimed: "A plague on both your houses, Union and Corporation." And they gave heed; for a strike or a lock-out without public sympathy is bad business. It is not often that the public expresses itself so quickly or so clearly. On this occasion there were two factors which stood out from the confusion of conflicting statements; one was discreditable to the combination of many men represented by the Labor Union and the other was equally to the discredit of the combination of the few, the Corporation. After the last strike, the men of the Union, by their duly chosen representatives, signed an agreement accepting a certain rate of wages and hours of work, and binding themselves not to strike during the term of the agreement, which expires next year. This contract they broke. We know, of course, that since the earthquake-fire, they have had to work under difficulties and in the face of steadily rising prices; nevertheless, a contract is a contract and among people with any sense of honor, the breaking of it is the mark of a bad citizen. It may be that the Corporation would have shown as much sense as generosity, if it had volunteered to abrogate the contract, having regard to changed conditions, but as it did not pursue such an obvious policy, it remained for the car-men to live up to their agreement like good Americans. No man is a good American who goes back on his word. A true man has the spirit of a sportsman, in the higher sense, he 'plays ball' no matter how badly things are going against him. By their precipitate action, the men of the Union forfeited the sympathy of the community.

On the other side, it was apparent that the United Railroads Company was forced into an exacting attitude because, being a much over-capitalized concern, its officers could not make such concessions as would entail a diminution of profits. The greed of a corporation is often the logical result of heavily watered stock. By that kind of financial manipulation the dishonesty of which is held by the unthinking to be condoned by its cleverness, the promoters of public utilities are enabled to make fortunes over night, passing a heavily burdened

business to men who then can only make it pay by becoming deaf to the dictates of humanity. On the present occasion the community recognized that the United Railroads had disregarded the well-being of the city, and though it approved the demand for a fulfillment of the contract made by the Union, there was a distinct feeling that the Corporation had been overbearing at a time when a little tact and consideration would have obviated any rupture.

The strike will have proved a blessing if it has impressed the representatives of both capital and labor that there is a third party to be reckoned with, and that either will forfeit the support of public opinion if it disregards the sanctity of a contract or the well-being of the community.

ALL ALONG the Mother Lode in California, and chiefly in the counties of Amador, Calaveras, and Tuolumne, there is a shortage of machine-miners, and even mine-laborers. In the region mentioned many of the miners have lived in the same locality since childhood and have had steady employment. Now, however, the unusual conditions at San Francisco and in Nevada threaten almost to depopulate these old mining centres. High wages have attracted many to Nevada who make no distinction between the comforts of home life in the foothills of California and a rough time in desert camps. They want the higher wages even though it may not increase their bank account a single dollar or add one comfort to their existence. The re-building of San Francisco, San Jose, and Santa Rosa is giving employment to thousands, so that artisans are in demand at high wages. Of the laborers, the railroads are employing an unusual proportion, and many have left the mines for this kind of open-air employment. The orchards and fields also need the usual percentage of wandering population.

IN THIS ISSUE appears the second portion of Mr. R. Gilman Brown's article on 'Cyanide Practice With the Moore Filter.' To those millmen who employ cyanide this description of the practice at the Standard mine will prove interesting and useful. The Standard at Bodie has been one of those mines that continued profitable long enough, and presented problems sufficiently difficult, to afford good training to several successful professional men. Thomas H. Leggett, R. G. Brown, F. L. Bosqui, Theodore J. Hoover and R. C. Turner may be mentioned among those who gave knowledge to, and took experience from, the old mine—that is, old to us in the West. In this last development of metallurgical practice we have the application of a method of filtering, the details of which are likely to be modified by each manipulator. It is the invention of Mr. George Moore and some of its mechanical features have been since improved by Mr. Charles Butters, with further modification by Mr. H. R. Cassel. Now that millmen have broken away from the filter-press, there is likely to be plenty of ingenuity displayed in the devising of filtering machines that can strain slime on a large scale and cheaply. In this direction lies the hope of a decisive reduction in the cost of cyanidation.

By the Way.

THE GOVERNMENT MINING ENGINEER in the Transvaal has published his report for the last half of 1905 and gives some interesting data.

The average number of stamps running during the half year was 6,567, as against 6,162 for the previous half year. The duty per stamp per 24 hours averaged 5,032 tons, as against 4,965 tons for the preceding six months. In December, 1905, the producing mines of the Witwatersrand were giving employment to 18,797 persons per stamp, as compared with 20,003 persons per stamp during June of the same year.

The following figures show the work done by the gold mines of the Transvaal during December, 1905, as compared with August, 1899, before the war:

	August, 1899.	December, 1905.
Number of stamps at work.....	6,070	7,294
Tons ore crushed.....	856,233	1,041,092
Duty per stamp per diem, tons.....	4.86	5 108
Total yield, ounces.....	410,965.05	430,985.804
Fine gold per ton crushed, dwt.....	9.599	8.279
Yield from mills only, ounces.....	265,584.10	270,327.563
Percentage of yield from mills.....	64.624	62.723

During the half year the yield per ton crushed by gold mines, based on the officially declared output, which does not include gold contained in by-products not treated at the mines, was 8.220 dwt. per ton. Including the gold estimated to be contained in the products sold, the total yield per ton crushed is found to be 8.285 dwt. per ton.

The following statement shows the number of mines using machine-drills, and the average number of drills in use since June, 1902:

WITWATERSRAND AREA ONLY.		
	Number of mines using machine- drills.	Average number of machine- drills in use.
1902, June.....	50	671.0
" December.....	60	994.0
1903, June.....	68	1,313.7
" December.....	72	1,561.2
1904, June.....	70	1,631.0
" December.....	76	1,746.1
1905, June.....	78	1,647.4
" December.....	79	1,898.1

The average percentage of waste sorted from rock hoisted during the half years was 16.6, as against 17.62% for the preceding half year.

MINING IN JAPAN.—On his return from a professional journey to Japan, Mr. R. J. Frecheville was interviewed while passing through San Francisco, and he delivered decided opinions in regard to the lack of a good opening for the profitable investment of the British capital he represents. Anglo-American companies would bankrupt themselves, he considered, in trying to pay expenses in mines that are yielding rich returns to the Japanese. He found much to surprise and interest him in the Japanese mining districts.

"I found at Kosaka," he said, "mining on a scale that astounded me. The ore there runs about two per cent copper and carries a little gold and silver. It is easy of access and they have a well-equipped smelter, which handles about 1,000 tons of ore per day, and they are clearing about \$250,000 every month. Before they built their plant they sent their own engineers all over the world, helped themselves to the best ideas they encountered, and have embodied the knowledge thus acquired into what is probably the most perfect mining and smelting plant in the world. They have electric haulage, aerial tramways, and a fine water-jacket plant. They employ about 3,000 men and their payroll amounts to next to nothing. If a foreign concern tried to operate

there and pay the same wages it would be accused of oppressing the people and, anyway, no foreigner could get anything like the same amount of work out of these Japanese laborers. All over Japan I found conditions the same. The Japanese loves his native village, and will work for a pittance without complaint if he can get that work without leaving home. During the harvest season all hands quit the mines and gather the crops. Not only do the men work, but they take their wives and children into the mines, and these auxiliary forces render invaluable service as ore-carriers. In large mines and small I found the same conditions. Low-grade ore everywhere, but cheap labor and plenty of it. The country is hilly and the mines are worked by running drifts into the hillsides. This saves the expense of pumping, which is quite an item under our methods. Japan's mines are of great value to Japan, but no good to anyone else."

AUSTRALASIAN GOLD YIELD.—The production of gold in the States of Australia and in New Zealand shows a slight decrease for the last six months, ending June 30.

	First Half-Year 1905 Fine Oz.	First Half-Year 1906 Fine Oz.
Western Australia.....	965,372	904,861
Victoria.....	338,747	381,681
New South Wales.....	111,869	133,150
Queensland.....	290,478	251,986
New Zealand.....	238,085	252,001
Total.....	1,944,541	1,923,679

To which must be added the output of Tasmania, about 35,000 ounces.

The most noteworthy feature is the continued decline in the yield from Western Australia, where the gradual exhaustion of the big, rich mines is not being balanced by the development of new prospects. During the past three months the most encouraging feature has been the finding of good ore in the bottom workings of such famous producers as the Great Boulder Proprietary, Golden Horseshoe, Ivanhoe, and Kalgurli, all at Kalgurli. However, despite the falling off, Western Australia still produces about one-half the gold that comes out of Australasia. For the last half-year her share was 47 per cent.

In Victoria there is healthy advancement, the increase for the first quarter having been 16,437 oz. and for the first half-year 42,934 oz. The total for the six months is the best in 30 years. The Bendigo, Walhalla, and Warrandite districts show the greatest gains. Dredging is also credited as a factor in the increase. If the 'deep lead' companies, which look promising, should overcome the water in the old alluvial channels, there will be a marked increase in Victoria's gold production.

In Queensland recently there has been an accelerating rate of decrease, but it is pleasant to note that other branches of her mineral industry—such as copper and tin—exhibit prosperity. In New South Wales, the increase was mainly in May and June, the production being curiously variable from month to month. In Tasmania, the output is 35,000 oz. for the half-year, the Tasmania mine at Beaconsfield and the New Golden Gate at Mathinna being the chief producers. In New Zealand there is a steady gain; the Ohinemuri and Thames districts are prosperous and the great Waihi mine continues to hold its own. In Otago the dredges are doing fairly well. On the whole, therefore, the gold mining industry of Australasia is thriving; it is a continent large proportions of which are comparatively unprospected, and this fact must be taken into account when estimating the future production. At the present rate the production for 1906 (including Tasmania) will be worth \$80,000,000.

Special Correspondence.

London, England.

Market Fluctuations. The Camp Bird Annual Report. Esperanza and El Oro Production. Rich Ore Reported in the Bottom of El Oro. Some Cornish Returns.

The improvement in the Kaffir market affords an opportunity to the inevitable share-pusher to invite the public to "come in" and buy shares with a certain prospect of dividends of from 5 to 7% and a good probability of a market rise. It is to be hoped that speculators will not be so foolish as to follow this advice; stock in a mine however well established and wherever situated is not worth buying at par if it does not yield or show the probability of yielding in the near future well over 5%. A notable case of unexpected fluctuation in a first-class mining stock during the last few days is the Mysore, the drop being caused, it is thought, by the fear that owing to the death of Sir Charles Tennant, his big holding is in course of liquidation, combined with the recent history of Champion Reef, although it is stated on the highest authority that so far as the Mysore mine itself is concerned there is nothing to warrant any uneasiness as to the stock. Special attention is being drawn to Tanganyikas on the rumor that the Lobito railway scheme is being backed by prominent American capitalists who are eager to share in the "vast copper wealth shortly to be brought into commerce" in that part of Africa. Mr. James Liddle (consulting engineer for the De Beers) is cited as an exponent of the good things awaiting the employment of capital in Africa. This gentleman is reported as having been on a tour of the entire United States for the purpose of studying mining and milling conditions and to investigate the practical application of recently invented machinery to every-day use. While stating that the development of the mining industry in the United States is wonderful, and that the industry will be enormously greater a few years hence, Mr. Liddle is reported to hold the opinion that the mining industry in Africa is still in its infancy. There are enormous areas to be explored, and it seems certain that these great areas, when they have been explored, will show even greater wealth than those that have been opened.

The report just issued by the directors of Camp Bird, Limited, for the year ended April 30, states that, after providing for every description of expenditure, the accounts show a profit for the period of £175,064. Deducting £35,370 for estimated losses due to snowslide and fire in March, 1906, namely, stores, £5,370, and stamp-mill, £30,000, and adding £111,940, brought forward, there is a total of £251,634. The three dividends of one shilling each paid during the year absorbed £123,000, directors' remuneration of 1% £1,396, and income tax to date £11,617, leaving £115,620, which it is proposed to carry forward. For depreciation of plant, £10,024 has been written off, this amount being 10% of the estimated value of the equipment as at April 30, 1905. Development has proceeded satisfactorily, a total of 7,371 ft. having been driven, raised or sunk. After treating 66,223 tons of dry ore, the reserves were 120,477 tons broken in the stopes and 90,443 tons blocked out, making a total of 210,920 tons of dry ore in reserve, which Mr. A. C. Beatty estimates will yield a profit of approximately \$4,300,000, after realizing a net profit during the year of £175,065 and paying Mr. Thomas F. Walsh £59,066. From the ore treated during the year an extraction of 95.53% of the gold values has been obtained, making \$28.57 per ton. Exclusive of depreciation of plant and cost of re-

construction, the total cost at the mine was \$9.90 per ton. All machinery had worked satisfactorily up to the time of the disaster. The work of reconstruction is progressing favorably, and it is hoped to have the new stamp-mill erected and in working order during December next. In regard to Imogen Basin Gold Mines it is stated that up to April 30 £27,663 was expended, Camp Bird receiving 540,000 shares of £1 each in the Imogen Basin Company.

Mexican mining returns for July are beginning to come forward. The cabled report of Esperanza for the month is as follows: The mill ran 29 days and crushed 13,890 tons of dry ore; shipped to smelter 6,784 tons of dry ore; estimated realizable value of bullion produced, \$147,225; estimated realizable value of concentrate, \$81,563; estimated realizable value of ore shipped to smelter, \$481,131; receipts from rents and other sources, \$1,486, making a total of \$711,405; less working expenses, including development, marketing of bullion, freight and treatment charges on ore shipped to smelter, \$292,998; allowance for depreciation of plant, \$2,500; consulting engineers' fees and New York office expenses, \$2,546, aggregating \$298,044; estimated profit, \$413,361, less London expenses of about £250. Of this there has been expended on construction account \$4,744 and prospecting on Suceso property \$3,215.

El Oro reports that in July the No. 1 100-stamp mill ran 29 days, and together crushed 22,378 tons of ore; total estimated realizable value of the product, \$180,490; less working expenses, \$92,843; less development expenses, \$10,238; profit, \$77,409; profit from the railway, \$9,388; total, \$86,797, less London expenses and general manager's salary, £700. The sum of \$3,095 was expended during the month in permanent improvements. (The amounts in each case are in U. S. currency.) Under the heading of 'Good News for El Oro,' the enterprising financial editor of a London daily paper states: "We have received a cabled communication from our correspondent in Mexico of an important nature, not only to shareholders in El Oro Company, but also to those in the Esperanza Company, and to everyone interested in the field. It is to the effect that the news of the rich strike made on the San Rafael vein in El Oro mine is fully confirmed, rendering the value of the entire district considerably greater even than it was supposed to be. It appears that it is after several years of diligent search that El Oro has struck the exceedingly rich sulphides corresponding to those in the Esperanza, and that this substantiates the value of the deep levels of both companies. The cablegram adds that the Esperanza output this month will be the largest it has ever made, and that the whole district is very jubilant."

Following the example of its neighbor, Dolcoath, the accounts of the Carn Brea & Tincroft Mines, Ltd., show a striking advance on previous records of late years. The profit on the six months amounts to £10,162, due to a certain extent to the higher average prices of ore sold.

SUMMARY OF THE ACCOUNTS.

Tin stuff crushed.....	30,055 tons
Black tin sold.....	402 "
Produce per ton of stuff.....	30 lb.
Average value per ton of stuff.....	£1 5s. 4d.
Average price per ton of tin, including slime tin.....	£94 18s. 4d.
Amount realized.....	£38,186 0s. 0d.
Total receipts.....	£44,442 0s. 0d.
Per ton of stuff.....	£1 9s. 6d.
Working costs.....	£34,280 0s. 0d.
Per ton of stuff.....	£1 2s. 9d.
Profit.....	£10,162 0s. 0d.
Per ton of stuff.....	6s. 9d.

The manager (Captain John Penhall) states that the high prices of all the minerals sold have told greatly in favor of the mine. The new concentrating plant and machinery recently completed at the dressing floors are working satisfactorily, and tailing is now being treated which formerly could not be touched.

Butte, Montana.

Trespassing on Railroad Property. Improvements at the West Colusa, High Ore and Corra Mines. New Veins Cut in the Butte-Argenta and the Eagle. Good Developments in the Rarus and Alliance.

With the proof of the value in quartz veins south of the Butte hill, where the land is covered with wash to some depth, and was originally taken for placer mining, there has been a scramble on the part of speculators to make locations on territory which is for the most part patented placer ground. Against the owners of several of these claims the South Butte Co., which appears to be the holding company for the mineral rights of the Montana Central, has brought suit. H. V. Winchell, formerly head of the Amalgamated geological department here, but now chief geologist for the Hill interests, is named as one of the plaintiffs. It would seem that the Hill interests are getting in shape to work their mineral holdings in this section in the near future, and the fourteen suits instituted are evidently to quiet title. Among the claims located, in whole or in part, on this railroad territory are some belonging to the Alliance, Green Copper, and Butte Central companies. The only company which was actually working the ground was the last mentioned, and it has been enjoined from continuing operations. Mr. Winchell says that the mineral lands belonging to the Hill system are being placed in the hands of holding corporations separate from the railroad company, so that they can be more conveniently handled.

The Boston & Montana Co. has closed down the West Colusa shaft for repairs. In the meantime the Leonard, which is connected on several levels with the West Colusa, has increased its payroll considerably, having over 900 men on the roll at present. The West Colusa shaft is the only one in camp with cages large enough to take mules and horses down without binding them and putting them in a sitting posture. The animals for the Leonard are taken down this shaft. The connections of the mines are however not such that much work can be done in the West Colusa during the shut-down, and probably little ore will be mined in the workings of this mine for the next month or six weeks. The Mountain View mine, which opened up last week, will keep the company's output at about the usual mark, and some West Colusa ore will be hoisted by the St. Lawrence.

The High Ore mine has nearly finished cutting the station on the 2,400-ft. level, and sinking will be begun in the pump-shaft soon. The High Ore mine, which is situated on the Belk claim, was sunk originally by Marcus Daly mainly as an air and pump-shaft, to take care of the water from the hill mines; but, owing to the fact that the shaft is in some of the best ground on the hill, the mine has been developed with good results. The ore has been found rather more in pockets than in the other large mines in the vicinity, however, and at present only about 700 tons per day are being hoisted, although the mine is one of the biggest in Butte. On several levels there has been a large amount of cross-cutting to the north of late, and it is thought that some of the veins that enter the North Butte property farther to the east will be worked from this shaft.—The old Berkeley shaft, which has recently been put in commission by the Butte & Boston Co. after several years of idleness, is now yielding 400 tons of copper ore per day. The same company may soon open up the old Silver Bow shaft No. 3, which has also lain idle for a long time. This shaft will be used to facilitate the workings of the Silver Bow mine, which is now being worked through only one shaft, but which contains some good veins, and is expected to make a big ore producer.

The Minnie Healey has been closed down for repairs to the shaft. The shaft of this mine has been cut down by the Rarus fault, and has always been in rather poor condition, the ground being soft for a long distance. It is not known how soon work can be resumed, as the condition of the shaft has been very bad for several years, and has lately become so that the cages could not be run through it. The water from the mine will be run through the Leonard and pumped out of that shaft. The Minnie Healey has been yielding 350 tons of ore per day to the Red Metal Co. for some time past.—The Corra shaft, which has been in the process of sinking, is now within 150 ft. of the 2,400-ft. level. A station is being cut at the 2,200-ft. level. The Corra is one of the oldest copper mines in the district and was a good producer while in the hands of Heinze. The Red Metal Co. intends to open it up in good shape.

The Butte & Furnace Creek Copper Co., which was organized here some weeks ago, with John McGinniss, the mayor of this city, as one of the chief promoters, has changed its name to the Furnace Creek Extension Copper Co. George W. Irvin, postmaster at Butte, is president of the corporation. Their claims are in the Funeral range, Inyo county, Cal.—The Pittsburg & Montana Co. has leased its mines near Helena to some parties from that city. The mines were chiefly valuable for the silica in the ore, which made a flux for the Pittsmond ore while the company were running their own smelter here. The copper ore is now being shipped to the Washoe smelter.—The Butte Argenta Co. has cut a vein of copper ore in their claims at Argenta. The vein is 30 ft. wide, but the ore is low-grade, running less than 4% copper, with a little silver and gold. The company hopes to get a spur from the railroad and then will be able to ship the ore and get a return which will yield a profit.

The Eagle Mining Co., working the Eagle claim, has struck some stringers of peacock copper ore on the 200-ft. level. The mine yielded good silver ore years ago, and has been producing again this summer in the hands of the new company. There is not much of the copper ore, but it is remarkable as being found in a region where copper has not yet been found in rich deposits, the mine being north of the old silver mines of La France and the Walker brothers.—In the Rarus mine of the Red Metal Co. the vein known as No. 16 has been cut on the 1,600-ft. level. This opens up a large reserve of ore for the company, and will probably enable the Rarus to make an output compensating for the closing down of the Minnie Healey shaft.—The National Mining & Smelting Co., of Salt Lake, have filed notice of a change of name of the company to the New York and Salt Lake Copper Mining Co., and the capital stock has been increased to \$5,000,000, in \$10 shares.

The Montana Zinc Co., which operated the old Alice mill that recently burned down, has not yet received the insurance, and so is not in a position to make final plans for the future.—The North Butte Co. is taking out about 1,100 tons per day from the Speculator shaft, an increase of 200 tons as compared to a week ago. This is due largely to the increased facilities made by the installation of the skip-chutes and ore-pockets, which have been completed on the 1,200-ft. level. There will be a further increase of output shortly when the chutes and pockets on the other two levels are completed.

The Alliance Copper Co., which owns a large piece of placer ground near the Montana Central yards in the south part of the city, has struck a vein of copper sulphide in their Alliance shaft. The vein has already produced shipping ore farther to the west, and some of the claims on the same vein are the objects of the suit and injunction by the South Butte Co. above mentioned. The Alliance

company is associated with the Farrel Copper Co. which owns a large tract of placer ground just south of their land. With the present dip of the vein it will stay in the ground of the two companies for several thousand feet in depth. The Alliance shaft struck the vein not far from the surface, but did not encounter the orebody until near the foot-wall. They are now raising to explore the extent of the ore, which runs 16% copper in grab samples. The ground lies to the southwest of the East Butte Co.'s holdings, and is about the southern limit of the copper-producing country hereabouts. The shaft of the Moonlight mine of the Washoe company has received a 200-ft. extension through the raise from the 1,500-ft. level of the Never Sweat. The new part of the shaft will not be used immediately for mining purposes, being raised primarily to supply air in the Never Sweat. The raise was made on stope-sets instead of shaft-timbers, but when the Moonlight is ready to use it, these will be replaced by regular shaft-sets.

Bisbee, Arizona.

Increased Output of Copper. The Orebodies in the Shattuck-Arizona Mine. New Equipment. Diamond-Drilling in the Denn-Arizona. Good Prospects in the Cochise.

The month of August showed an increase in the output of copper from the Warren district. At the Copper Queen smelter, at Douglas, the output exceeded that of any other month, excepting March, when the gross output was 8,750,000 lb. of copper. Production at the Calumet & Arizona was normal. The output at the Copper Queen was 8,500,000 lb., and at the Calumet & Arizona, 3,950,000 lb. There is no material change in the equipment of any of the smelters.

The hoist at the Cuprite shaft on the Copper Queen property broke down on Friday evening. It was necessary to close down for repairs, but work was started again on Saturday. This was the only incident this week on the Copper Queen holdings. Everything is about the same as usual at the Calumet & Arizona, and Superior & Pittsburg properties. The tramway on the Shattuck-Arizona property has been working for the past week in a satisfactory manner; 200 tons of ore are being hauled over the tramway every day, and loaded at the railroad spur. The average will be increased after a month or six weeks to 300 tons. Shipments are being made to the Copper Queen smelter at Douglas. On the 800-ft. level there is a new sulphide orebody, which is one of the richest yet encountered in the mine. The ore averages about 25% copper. The two raises from the 800 to the 700-ft. level are both in oxidized ore, and stopes will be started this week. On the 700 five orebodies are being opened up. There are four stopes on the 800 at the present time, and eight on the 700. The drift on the 600 is in lode-matter and iron ore. The material for the new office building is now on the ground, and the work of erecting the structure will be commenced this week. A clearing has been made for the new building back of the tramway terminal. The hoist borrowed from the Junction people has been put into commission and all of the hoisting at the present time is being done with this engine. It was erected on the opposite side of the shaft from the old engine-house. The old hoist is being used at the present time on the single-deck cage. A new building is to be erected on the site of the old engine-house and the new Sullivan air-compressor will be placed there as soon as it arrives. The Junction hoist will be used until the new Allis-Chalmers hoist, which was ordered some time ago, arrives. At that time a new engine-house will be erected, and the equipment on this property will then be complete.

At the Denn-Arizona, sinking of the shaft was resumed today. It was necessary to discontinue work in the shaft a couple of weeks ago on account of the breaking down of one of the pumps. The pump was repaired, and is working satisfactorily. The stations for the Prescott pumps have been completed, and the work of laying the foundations for these big pumps is now under way. The east drift, on the 1,000-ft. level, has been driven about 600 ft., and is now in a limestone and iron formation. The cross-cut, which will be run to the diamond-drill bore, will be run in accordance with the surface position of the bore. It is expected that the hole slants with depth, but this will not be taken into consideration until the cross-cut approaches the vicinity.—At the Cochise property a material change was noticed in the shaft this week, when the 700-ft. mark was reached. Red iron oxide was encountered, and since that time talcose matter carrying a low percentage of copper has been exposed. It is a brecciated formation, and the outlook is favorable. The drift on the 300-ft. level is still in limestone. It is understood that a drift will be driven southwest on the 700-ft. level, but this matter has not been definitely settled. The finding of iron in the shaft has been looked upon very favorably, as it has almost invariably been a forerunner of copper ore in this district.

Melbourne, Australia.

The Mine Fires at Broken Hill. The Proprietary's First Spelter Plant. Discovery of Carnotite at Olary. The Deep Leads in Victoria. The Great Cobar Flotation. Luck of the Lessees and the Story of Gold Found in the Copper Ore.

In my last letter dated April 12 and written before the news of the earthquake at San Francisco had shocked Australia, I dwelt on the injury done to investment in Broken Hill through the fires at the Proprietary and the Junction mines. Since then the fire has been completely subdued in the Junction, but not without the adoption of heroic measures. As no progress was being made in combatting the outbreak, as there were signs of a serious collapse of the Junction North shaft adjoining, and as the men in the North and British mines were unable to work except at great risk from the pyroligneous fumes from the burning Oregon pine, it was decided to flood the Junction mine. This meant also flooding the Junction North and the North Broken Hill mines practically to the 400-ft. level. Broken Hill is an arid region with a poor water-supply, but the elements were kindly and the three companies were furnished with water at 2s. 6d. per 1,000 gal. by the local water-supply company as against 5s., the usual charge. It took about 70,000,000 gal. to flood the mines and about three months' idleness. But the fire was beaten. Now the water is out and it can be seen that the Junction North shaft has practically collapsed and that one of the Junction shafts has been rendered useless. The loss to the companies has been very great, as they have been bereft of a highly profitable lead market and have had to incur much expense in fighting the flames, in flooding and unwatering the mines, and in making good the damage done by both fire and water. The shares of the three properties mentioned are all largely held by the British public as the result of the incursion of Messrs. Bewick, Moreing & Co. into Broken Hill, and regret is felt that a check should have been administered to their enterprise. Before concluding this paragraph it is fair to state, and I hope equal publicity will be given to the denial as to the assertion, that the impression has now reached the stage of a certainty that the suggestion that the fire in the Junction mine was the result of overt

action by any dissatisfied persons was wrong. This is most gratifying to everyone. The Proprietary fire has also been got under control and the company is now engaged in turning out over 40,000 tons of ore per month—or as much as the whole of the other mines put together. It may be added that the company has just completed the first unit of its spelter plant at its Port Pirie smelting works. It is only a small affair—100 tons per week—but when the company gets the knack of the work and learns the best clay to use for its retorts, then other units will be added in quick succession. A self-contained organization, the company is relying on its own staff for skill.

A very interesting mineral discovery has been made at a wayside mineral district called Olary, on the way to Broken Hill. This is the striking of a formation carrying the rare mineral carnotite. The Government Geologist of South Australia (H. Y. L. Brown) writes of the find: "There are two lodes running parallel and from 5 to 15 yd. apart. The ore occurs as yellow and greenish incrustations and powder on the faces and joints, and in cavities of the lodes. It is visible along the outcrop at intervals, but best developed along some 50 ft. of the more solid and continuous portion, which has a thickness of from 24 to 42 inches. Judging from the persistent character of the lode itself, on the length of outcrop, and its width, where visible, I am of opinion that it will be found to extend to a considerable depth. From the fact that the carnotite occurs as incrustations, it appears most probable that it has been derived from the solution and re-deposition of other uranium compounds below, and therefore such ores will be found by exploitation at depth." A picked sample yielded vanadic oxide and 12% uranium oxide. The find is more curious than valuable.

Deep lead mining in Victoria just now is in the doldrums. What would give it a fillip would be for the big English ventures at Moorlort, controlled by Bewick, Moreing & Co., to get onto good gold. The firm has spent scores of thousands of pounds, only to learn the lesson to the full, that there is no royal road to get into a deep lead with its contained burden of water. It is pump, pump, and yet again, pump.

Work at the Moorlort mine has been abandoned to concentrate operations on the Loddon Valley mine, and an additional sum of £80,000 has been subscribed in London to go on with the work. The only feature that calls for comment in connection with the raising of this capital is that an estimate by Mr. Waldemar Lindgren on the value of gold in the wash was given out, apparently to induce subscriptions. Now, it can be most plainly affirmed that there is no local alluvial miner who would dare to estimate the worth of a deep lead from bores put up from the main level under the lead. Everyone wishes that the enterprise will turn out a huge success, but dependence on any estimate of the value of wash—even when it is cut up into blocks—is often most misleading and should for that reason be avoided.

The flotation of the Great Cobar mine and its allied ventures into a huge concern in London has been taken very quietly in Australia. The fact of the matter is that the syndicate which obtained possession of the Great Cobar mine has kept the good thing pretty well to itself. The members of the vending syndicate include Dr. Reid, Mr. Gould, formerly a prominent politician in New South Wales and now of the Federal Senate, and the brothers Longworthy. It is improbable that these men ever realized that they had such a prize in their grasp when the Sydney directors of the original Cobar company agreed to let them have the mine on tribute. The syndicate thought that the property could be worked in connection with coal claims held by Dr. Reid at Rix's Creek near Newcastle, New South Wales. In this assumption

they were right and, as events turned out, they in addition got a great mine to work on a rising metal market. Then the syndicate nibbled in the majority of the shares in the company from which they held a tribute and so gained possession of the mine. As an illustration of how luck may go to one and not to another, it can be positively asserted that the syndicate had a narrow chance of missing the prize. Mr. Trewenack, a capable metallurgist, without being aware of the efforts being made by the syndicate to secure their tribute had been quietly sampling the slags and ore obtained by him at the mine. These showed the presence of gold in an appreciable quantity in the ore, besides the usual percentage of copper—a fact of which the directors of the original company appear to have been unaware. He got in touch with big capitalists and actually approached the company officials to try to get the mine on tribute but the board had gone too far and the next we heard was that an agreement had been signed. If he had acted a couple of weeks earlier, in all probability the fate of the Cobar copper mine would have been altogether different.

Salt Lake, Utah.

Stock Sold and Bullion Produced During the Past Month. The Honerine Mine Under Examination. A Discovery in the Daly.

Park City's Output. Repairs in the Ontario Adit.

Ore Shipments From Tintic.

The directors of the Mammoth Mining Co. have posted a dividend of five cents per share, or \$20,000, payable on September 20. The ore and bullion settlements at Salt Lake City during August amounted to \$2,423,000, the last week's portion being \$596,000. During the month stated the sales of the Salt Lake Stock & Mining Exchange reached 1,010,112 shares, the same selling for \$727,534.63. It is estimated that the output of gold, silver and copper-bearing bullion from the Salt Lake valley smelters during August aggregated close to 7,000,000 pounds.

The Utah Apex Mining Co., of Bingham, is pushing work on the lower terminal for the aerial tramway to operate between the mouth of the Andy tunnel and the Copper Belt railroad. With the tramway in operation, Mr. A. L. Pearce, the company's consulting engineer, says the management will be enabled to handle an output of 100 tons of ore daily, which will net \$10 per ton. Information received from Gold Butte, situated in the extreme southeastern part of Nevada, states that the adit through which the Gold Butte mine is being developed has been run 275 ft. Important developments are expected within the next 100 feet.

Mr. E. W. Clark, manager of the Ophir Hill mine at Ophir, and a corps of assistants, has been conducting an examination of the Honerine mine at Stockton, which has led to the belief that the investigation is in the interest of Mr. W. A. Clark, of Montana, although owners of the mine refuse to confirm or deny it. — What appears to be an important orebody has been opened on the 1,200-ft. level of the Daly mine at Park City. — Development work will shortly be resumed at the Thompson mine at Park City. J. D. Wood, of Salt Lake, has been made manager. An effort is being made to operate through either the Daly-Judge or the Daly-West mine.

Ore shipments from Park City mines last week aggregated 2,543 tons. The shippers and amounts were: Daly Judge, 745; Silver King, 738; Daly-West, 500; Little Bell, 258; New York, 40; Ontario, 241; Jupiter, 11. — The output of the Little Bell mine at Park City in August was about 1,000 tons of ore. An air compressor, to operate ten drills, has been installed. — It is believed the task of unwatering the camp through the Ontario drainage adit at Park City, which has been closed by caves

for over eighteen months, is drawing to an end. Heavy timbers are being put in the cross-cut, this being done from the drift paralleling the main channel across which has been placed a door weighing one and a half tons, the latter being installed as a protection to workmen.—Important developments have been made in the Treasure Hill mine at Park City, which will soon become a shipper of ore.

The new compressor plant at the Yankee Consolidated mine in the Tintic district, replacing the one destroyed by fire recently, will be in commission in a few days.—Ore shipments from the Tintic mining district last week amounted to 128 carloads, or a little over 5,000 tons, the shippers and amounts being: Grand Central, 6; Victoria, 3; Carisa, 10; Mammoth, 7; Star Consolidated, 1; Black Jack, 1; Ajax, 2; Bullion Beck, 9; Gemini, 10; Centennial Eureka, 39; Scranton, 5; Dragon Iron, 8; Swansea, 4; Beck Tunnel, 2; Uncle Sam Con., 8; Eagle & Blue Bell, 2; May Day, 3; other mines, 4.—At the annual meeting of the shareholders of the Ohio Copper Co., N. J. Catrow was chosen president; A. J. Bettles, vice-president; Henry Catrow, secretary and treasurer, who, with J. S. Gard, J. H. Friend and Thomas Weir are directors. Mr. Weir is also manager. A bond issue of \$650,000, the proceeds of which are to be used in the further development and equipment of the mine, was also authorized. The mill is to be enlarged. It is now treating 200 tons per day and making a saving of about 85 per cent.

Toronto, Canada.

Rich Discovery in the Nipissing Mine at Cobalt. Canadian National Exhibition.

The sensation of the last few days in mining circles has been the discovery of an extraordinarily wide and rich vein on the Nipissing Mining Co.'s property at Cobalt. Three weeks ago a new vein was struck near Vein No. 23. Where first discovered it was about 18 in. wide, when uncovered and followed it gradually widened until about the end of last week it was found by actual measurement to be five feet wide with an outcrop of almost pure silver. A large nugget weighing about 800 lb. was taken out, and is thought to contain 70% silver. Prof. W. A. Parks, of Toronto University, who was in Cobalt at the time, assisted in the measurement of the vein and vouches for the correctness of these details. The vein has been followed for a distance of 150 ft. The locality has been passed over by hundreds of prospectors since the camp was established, and the circumstances under which the find was made indicate that the thorough and systematic methods of prospecting pursued by large companies like the Nipissing, possessing abundant capital, must replace the crude and haphazard operations of the early prospectors before the real wealth of the district can be ascertained.

The Canadian National Exhibition opened here on August 27. The Temiskaming & Northern Ontario Railway Commission contributed a collection of ores and minerals from the Cobalt camp and neighborhood, which is attracting widespread attention. It is a representative display. The most conspicuous feature is three large nuggets from the Nipissing Mining Co.'s property weighing 485, 180, and 150 lb., of the respective values of \$650, \$300, and \$250. Three bars of pure silver, weighing altogether 136 oz., are shown, the product of 90 lb. of ore from the McKinley & Darragh mine. Smaller pieces of ore are displayed from the Foster, University, Gilpin, Silver Leaf, Silver Queen, and other mines. The Ontario Government supplies four specimens of silver-copper-nickel ore from the recently discovered vein on the Gillies timber limit, and a slab of native silver from the Tretheway mine, valued at \$500.

The Development & Finance Co., of London, England, has bought 13 mining properties in Wakefield and Templeton townships, near Ottawa, recently sold by the sheriff. — A vein of cobalite has been struck by H. C. Barber a few miles southwest of Cobalt.

Cripple Creek, Colorado.

The August Output. Larger Tonnage. Increase in Milling Capacity. Cyanidation Gaining Ground. No Leasing at the Portland.

During August there was an increase of ore sent to the mills and a decrease of that treated by the smelters. The average yield of the ore was less, on account of the large proportion of low-grade stuff that was cyanided. The figures are:

Plant.	Tons.	Average value.	Total.
U. S. R. & R.	26,100	\$27.50	\$719,400
Smelters	7,500	80.00	600,000
Portland mill.	9,500	26.00	247,000
Ironclad "	2,500	3.00	7,500
Anaconda "	1,500	4.00	6,000
Home Run "	600	12.00	7,200
Santa Rita "	100	7.00	700
Total	47,860		\$1,563,800
Last month	46,442		1,665,500
Gain in tons			1,418
Loss in value			81,700

Two more cyanide plants will commence operation during September and two more in October, it being evident that cyanidation is gaining as against chlorination in the treatment of low-grade ores. The Santa Rita mine was drowned out during August and this shut off the supply of ore to the mill. It has a capacity of 50 tons per day. The cyanide plant of the Wishbone Mining Co., on Carbonate hill, will start this week, at the rate of 100 tons per day. The Pony Gulch mill is also nearly ready for business. The carpenters at the new Isabella mill have nearly finished their work. This plant has a capacity of 250 tons per day. It is likely that the Elkton, El Paso and Stratton's Independence will have their own mills—to treat dumps and low-grade ore—in the near future.

An authentic report to the effect that a rich strike of ore has been made in the Ida May property on Raven hill by the Cripple Creek & Fort Collins Mining Co., contracting for Beryl Tolman and associates, was received in the city by the latter the other evening. The lease is being operated through the Raven tunnel of the Elkton Co., and is 2,000 ft. from the portal at a depth of 700 ft. The Fort Collins Co. also has a lease on the Constantine claim in the same neighborhood.

President Irving Howbert, of the Portland Gold Mining Co., announced to *The Times* that rumors to the effect that portions of the Portland are about to be leased are erroneous. "You may state that absolutely no part of the Portland will be leased," said Mr. Howbert, "despite rumors to the contrary." The Portland is reported to be in excellent physical condition and living well up to its record of 10,000 tons per month.—One car of ore per day is being sent out from the Ophir mine, on Raven hill, belonging to Mrs. Anna Cone, of Canon City. This big production is stimulated by litigation pending with the Jennie Sample, and the grade of the ore is high, running from two to three ounces in gold.

New machinery is being installed on the Vindicator No. 6 property by Hamor and associates, lessees. A steam hoist and a boiler are being put up and will be in operation within a few days. At a depth of 65 ft. these operators have a six-foot body of ore that has shipped \$60 per ton. Another lift will be sunk in the shaft, and it is the conviction of the lessees that with 100 ft. more depth, and corresponding development, the find will prove one of the best in the camp in several months.

Mining Summary.

ALASKA.

(Special Correspondence).—The Helvetia Gold Mining Co., on Windham bay, A. Gifler manager, is opening up its mine and treating the ore in a mill owned by W. Ebner, situated near the former property.—The Alaska-Treasure Gold Mining Co., on Nevada creek, near Juneau, is developing its mine, and has on the dock near the mine a complete 20-stamp mill. A large amount of ore has been accumulated on the dumps. It is expected to have the mill ready for operation by October 15. F. M. Stone is manager and M. T. Hudson superintendent.—The Alaska-Perseverance Co., near Juneau, is expecting to start up the new 60-stamp mill in the latter part of September. John R. Mitchell is superintendent.—At Hadley the copper smelter is running full time on ore from the mine near the smelter. James Parker, of Seattle, is manager.

Juneau, August 25.

ARIZONA.

It is stated that two smelters will be built in the vicinity of Tucson, and if this is done, it will greatly benefit the mining districts in Pima, Pinal and Santa Cruz counties. One of the smelters is to be erected by the Mowry Mines Co. at Calabasas and the other is to be built by the Imperial Copper Co., which owns the Silver Bell properties—the largest in Pima county. Articles of incorporation were taken out a few days ago by the Imperial people, who will build their smelter either at Silver Bell (which is 30 miles from Tucson) or at Red Rock, which is about 25 miles from that city and just across the line in Pinal county. This smelter will have a capacity of 200 tons, and will be so designed that the capacity can be easily increased.

It is likely that a considerable quantity of fluxing ore will be shipped to this smelter from the mines in Tombstone, for practically the same people who are interested in the Imperial Company are in the Tombstone Con., which gives promise of making Tombstone the lively camp that it was 20 years ago.

This company is rapidly disposing of the water which flooded the Tombstone mines and made Tombstone a dead camp. Pumps have been arranged on the 700 and 600-ft. levels, and the water is now under control, and the main shaft is being sunk. The company is shipping ore steadily to smelters at El Paso.

The Twin Buttes Co., which recently completed a standard-gauge road from its mines to Tucson, has begun ore shipments. The returns from the first 15 cars averaged \$238 per car, and the daily shipments bring about \$500 net.

COCHISE COUNTY.

(Special Correspondence).—The Consolidated Mining Co., embracing the Mammoth and Republic groups, continues to ship one car of ore per day; about 25 white men to 15 Mexicans are regularly employed. The Dragoon Mining Co. is shipping about three cars of ore per week. About 30 Mexicans are employed.

Capt. Johnson, who recently bonded the May Flower claim with no surface showing of ore, after prospecting the claim by open-cuts through wash to formation, has been rewarded by discovering an orebody. An incline shaft 6 by 8 ft., 40 ft. deep, shows ore all the way for 23 ft. in a solid mass which averages better than 8% copper. One car of ore was shipped from this work and further developments and regular shipments will be made as soon as timber arrives to take care of ground which is unsafe. This is the largest strike made at this depth since the early days of the Peabody. L. Ezekiel is superintendent.

The Empire Copper & Gold Mining Co., owning 12 claims, is working a force of eight Americans. Mr. Brooks, the manager, claims to have good indications of ore in the several shafts and tunnels, and expects to encounter a body of shipping ore at an early date. — The Michigan & Arizona Co., operating on the Copper Chief group, is sinking a double-compartment shaft which is at present 100 ft. deep. They have good showings of ore in several shafts and inclines, and some ore on the dumps. They expect to encounter ore in the development shaft at a depth of from 300

to 600 ft. Robert Mackay, the superintendent of the Black Prince Co., is pushing development work on that group. The Cochise Copper Co., operating on the easterly continuation of the Peabody group, is sinking a shaft (cage and manway compartment) on its property. They have attained about 150 ft., but are not yet through the wash, which covers the formation at this point. They expect to sink from 450 to 700 ft. before encountering the Silurian limestone, which usually serves as the foot-wall of the ore, at which point drifts will be projected. There are numerous prospect shafts on this property. The management claims no ore of commercial importance in sight. It is a close and well financed corporation, working in a manner necessary to good prospecting and development. Kirt L. Hart is manager; George M. Brown, superintendent.

Johnson, September 3.

MOHAVE COUNTY.

The Arizona-Mexican Mining & Smelting Co. is working a force at the Champion mine and getting rich lead ore. The company is to sink on this property, which was a big producer in the early days of the camp. Barney Perkins is preparing for a trip into the country south of Bill Williams fork, which is reputed to be rich in gold and copper ore, and prospectors from all parts are expected to be in there this coming fall and winter.—Wells Bros. have re-located the old I X L mine, in Wallapai mountains, and have been at work on it the past month. An adit was run to cut the vein at a depth of about 500 ft. and from this rich silver ore is being taken.—At Stockton hill there are now more men at work than in many years. The De la Fontaine mine is now being worked, and at the mill work is progressing rapidly.—At the Star Spangled Banner mine the Arizona-Mexican Mining & Smelting Co. is taking out rich lead ore. The mill is completed and will soon be in operation.—It is understood that there will be a consolidation of several of the large mines of Cerbat, and that later a reduction plant will be installed.—W. H. Taggart, of Los Angeles, has made a deal on the C. O. D. mine at Stockton hill.—S. A. Taylor is working four men on his mine east of Mineral Park. The orebody is said to be 14 ft. wide. The last carload shipment netted more than \$2,000. A carload or more of ore is on the dump awaiting shipment to the smelter.

CALIFORNIA.

AMADOR COUNTY.

Only 60 stamps running at the Kennedy mill—the other 40 heads are laid up, partly through lack of a full force of men in the mine. Safety clutches are being adjusted to the skips in the main shaft. Another large compressor, to run 15 additional machine-drills, is being installed. At the Argonaut sinking has been resumed. The shaft is to be sunk 200 or 300 ft. deeper. The present depth is 2,400 feet.

DEL NORTE COUNTY.

(Special Correspondence).—Charles Grover, of San Francisco, who holds an interest in the Hostler Joe and Peacock copper claims on Shelly creek, has placed the property before some parties who are interested. Mr. Grover has refused a cash offer for it, preferring, with the assistance of friends, to develop it.—J. N. Britten, owner of the Hard Luck claims on Shelly creek, is planning to install a mill and mining equipment.

MONO COUNTY.

In the Pittsburg-Liberty group, near Bridgeport, a rich strike is reported in a shaft 40 ft. deep, the entire bottom of which is in ore.—In the Kansas mine, near Antelope, an eight-inch vein has been cut, the ore assaying \$160 per ton.

NEVADA COUNTY.

Work has been started on the Lincoln mine, on Little Deer creek. A new shaft is to be sunk, under the direction of John R. Tyrrell.—At the Banner mine drifts are being extended on the 900-ft. level, and the shaft has been sunk an additional 50 feet.

SISKIYOU COUNTY.

The final clean-up for the season at the Lagrange hydraulic mine, west of Weaverville, amounted to between \$150,000 and \$160,000 in gold. Two other clean-ups were made earlier in the season, the first yielding \$76,000 and the

second \$32,000. The second clean-up was made on July 11 as an object lesson for several of the Eastern stockholders, who were then visiting the mine. The total for the season is over \$240,000 in gold as the result of operating three giants since early in January. The shut down is made now because of the shortage in the water supply. Work cannot be resumed until the rainy season, when water will again be plentiful, which will be in December. This season's run was shorter than usual, because the heavy snows last winter made it impossible to open up as early as usual. The cost of operating the Lagrange this season was \$60,000. The production of over \$250,000 in gold leaves a wide margin of profit. Forty men are all that are required to operate the mine and attend to the long ditch, the reservoirs and the flumes. The Lagrange is often spoken of as being the greatest hydraulic mine in the world. The anti-debris law does not interfere with its operation, for the debris passes into the Trinity and Klamath rivers, along which there are no ranches that can be overflowed.

TUOLUMNE COUNTY.

L. Baum, having mining privileges on the Ida Klein ranch, two miles east of Jamestown, on the Algerine road, for five years past, has been pocket mining with indifferent success. A month ago he took as partners John McFarland and J. N. Lyon, of Stent. They installed a 10-h.p. gasoline engine and a pump, which now handles the water. Work was resumed in the shaft and in a few feet a rich streak 18 in. wide was found, the ore being liberally sprinkled with gold.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The Red Oak Gold Mining & Milling Co. has sold its property on Democrat mountain to a group of Chicago capitalists headed by James A. and Elmer Bishop. Their expert examined the property about a month ago, spending a week at the mines, and the deal has just been closed. The purchase price is said to be about \$300,000. The sale was effected through S. B. Wright, of Denver. The property is well known throughout the county, and comprises the Scepter, Sunburst, Stewart, and Aston lodes, which were heavy producers 25 years ago, with 15 other lode-claims and three millsites. There is a cable tram from the mouth of the Scepter adit to the bottom of the mountain, where there is a millsite belonging to the property, inside the town limits of Georgetown. The new owners intend to erect a concentrator with a daily capacity of 100 tons at once, as there are large bodies of lead and zinc ore opened in the mine; as well as the 18-in. streak recently opened up which assays high in silver.

The Central mine, situated in the southeast of Georgetown, and of which David Kennedy is owner and manager, has a shaft down 600 ft. From this six levels have been driven east and west, and out of it some \$750,000 have been taken. The end of the 500-ft. level is 950 ft. west from the shaft under Leavenworth mountain, the breast of the level being 1,000 ft. below surface; in the last 200 ft. there is a body of copper pyrite five feet wide, which assays five ounces gold per ton and 17% copper. Mr. Kennedy is now driving an adit into Leavenworth mountain from the dump of the shaft. This is in 400 ft., and for the last 100 ft. there has been a body of quartz mixed with copper and iron pyrites four feet wide. This mills \$28 per ton as broken in the adit, and when concentrated yields four ounces gold per ton. There is difficulty in obtaining ventilation so as to work the ore in the 500-ft. level. The driving of No. 3 level 400 ft. and connecting No. 5 with it would be too expensive.

The Capital Mining & Milling Co. cut the Aetna lode with its main adit this week; the lode is well defined between granite walls and shows three feet of iron pyrite with a four-foot body of vein-matter. The adit enters the base of Griffith mountain, its mouth being within the limits of Georgetown. The Aetna lode was cut at nearly 4,000 ft. from the entrance, at a depth of 2,000 ft. The company has now reached its objective point, and will commence exploiting the Aetna, Brittle Silver, and other lodes cut by the adit. The manager, William Cooper, has the confidence of his company and of the citizens of Georgetown, so it is expected that before many months he will have the mine on a pay-

ing basis.—The Manhattan Mining & Milling Co., operating the Kitty Ousley mine in East Argentine, has a drift 1,500 ft. on the vein south from the adit which cut the vein at 248 ft. from the entrance. There are 700 ft. of stopes. Ore is exposed for the entire length of the drift varying in width from two to five feet, chiefly galena. This orebody widens out to over eight feet in some places in the stopes. Steady shipments are being made over the Argentine Central railway, which has two tracks to the mine.

The Terrible mill, above Silver Plume, is now turning out 200 tons of concentrate per week from ore broken in the Terrible mine of the Whiting Mining & Milling Co. and the Smuggler mine of the Main Gulch Mining & Leasing Co. — The foundation of the Diamond Tunnel & Corry City Co.'s mill at Silver Plume has been finished and the construction of the mill commenced. The mill will have a capacity of 300 tons per day when fully completed; a 150-ton section is to be finished by October 1. The mill will concentrate the material in the Diamond Tunnel & Corry City dumps, in which it is estimated there are over 1,000,000 tons of good mill dirt.

Georgetown, September 2.

LAKE COUNTY.

The Aetna shaft of the Glass-Pendery combination on Carbonate hill, Leadville, is down 720 ft. and will be continued to 850 ft. to the Parting quartzite, when lateral development will begin and be carried along that contact. This mine, one of the earliest locations of the district, was a heavy producer, but has not been worked since 1882.—The latest strike in Leadville district is in the Leopard mine, at the head of California gulch, a property under lease to Dwyer & Co. The lessees have opened an 18-in. vein of high-grade ore at a depth of 130 ft. Machinery has been placed and the shaft will be put down 100 ft. farther, when a cross-cut will be driven to the vein, which lies 500 ft. east of the Sunday mine.—Eighty thousand tons of ore were hoisted and shipped from this district last month, and from present output, so far, the total for the month of August will aggregate 90,000 tons, which is nearly equal to the combined tonnage of all the other metalliferous mining districts of the State.

SUMMIT COUNTY.

(Special Correspondence).—James H. Myers, general manager of the Lenawee Tunnel Reduction & Transportation Co., has recently built a 20-stamp mill on the property and intends adding 20 more stamps before the end of the year. The plant consists of stamps, jigs, Huntington mills, Wilfleys tables and magnetic separators. For the time being water for the mill will be supplied from a well, but a pipe-line will be laid to the Snake river, which is said to carry enough water to develop several thousand horsepower. It is expected that several mining companies will join in the erection of a power-plant. The Lenawee company has a 300-ft. adit. This property was worked many years ago from the surface, but it has been practically closed down since 1893. The adit is to be advanced several hundred feet farther. The mill dirt is said to average \$15 to \$20 per ton, while the shipping ore runs at the surface \$40 per ton. The company has recently taken over the Fisherman group of claims, consisting of 80 acres on which four veins have been opened, the principal one being opened by an adit 1,100 ft. long which shows an ore-shoot from 4 to 20 ft. wide. This property is about one-half mile from the mill, while the Lenawee tunnel has its portal at the top of the mill. The latter is situated about six miles from Keystone, the terminus of the Colorado & Southern Railway, and every effort is being put forth in this district to induce the railroad people to extend this branch to the mill, and eventually into both Montezuma and Argentine. The grade was started several years ago, but was abandoned for an unknown reason. Most of the grade has been completed as far as the junction of the two streams which form the Snake, and it is estimated that the track could be built at a nominal expense. Should the railroad continue its track to this district it will undoubtedly be the means of opening up many of the old abandoned mines as well as increasing the output from the already producing properties. The pipe-line for the projected power-plant will be approximately

7,000 ft. long and will have a fall of 350 ft. This portion of the district was one of the best in the county until a few years ago, and at the present price of zinc and lead it is bound to come to the front again.—It is understood the Bullion group has been disposed of to the Guggenheims, who are contemplating extensive improvements on the property. A large amount of development work has been done on the mine.—The local mine owners have organized an association and are endeavoring to pull together for the good of the camp. They report a shortage of men. This is true of every part of Colorado; managers are unable to secure miners.

Argentina, September 1.

(Special Correspondence).—There is an increase of activity in this camp. The New Pennsylvania Mines Co. is shipping two cars of ore per week and hauling the ore to Keystone, about ten miles distant. W. B. LeWald made the statement that as soon as the railroad would complete its line he was in a position to double the capacity of his mill. Several stockholders of the Pennsylvania company have been visiting the property and seemed well pleased with conditions.—The Rothchilds Gold & Silver Mining Co. has been operating here for years and is still driving an adit, now about 4,000 ft. long, and it is estimated that within the next 300 ft. the mother vein of Cooper mountain will be cut. The Tariff and Rothchilds are the two main veins and from indications on the surface they have apparently come together. Already 32 minor veins have been intersected; some of these give good assays, but the object of the adit is to tap the two main lodes, which at the surface are 15 to 24 ft. in width. This company is also considering the erection of a mill for the treatment of the ore which now has been opened up. Thomas R. Webb, formerly with the Gold Pig mine in San Bernardino county, Cal., is general manager of the Rothchilds property.

Argentina, August 31.

(Special Correspondence).—A good deal of work is being done in the Ten Mile district and especially at this particular point. The King Solomon Tunnel & Development Co. has cut four veins in the first 800 ft. of their adit, but it will be necessary to drive several hundred feet further before encountering the main lode. This company is considering the advisability of a power-plant on the Ten Mile river, which flows past the property. As both the Denver & Rio Grande and Colorado & Southern tracks are available, the shipping facilities are most convenient. Sam H. Alexander, secretary and fiscal agent of the company, of Madison, Wis., is on a visit to the property. F. C. Dinsmore is president and W. W. Theobald treasurer.—The Mary Verna mine was closed down a few days ago, but it is expected to resume operations shortly.

Frisco, August 31.

TELLER COUNTY.

A shipment of ore sent out from El Paso mine the latter part of last week gave returns of \$8,000, or five ounces per ton gold. There were three cars of this grade. Ore is coming from the Little May and Beacon Hill-Ajax claim, where work is being prosecuted by the company in addition to efforts of lessees in both claims. Recent developments in El Paso warrant the belief that enough ore has been found above the 600-ft. level, to which point the water has risen in the shaft since the recent influx, to keep the property producing steadily until the completion of the drainage tunnel which, if begun immediately, will be completed inside of three years.—A strike has been made by Bower & Beard, operating in the Glorietta shaft of the Vindicator, formerly belonging to the Hull City placer. These lessees are now working with two machines in a nine-foot orebody on the 100-ft. level, 80 ft. south of the shaft, returns on the initial shipment being at the rate of \$40 per ton. All the ore is being run through a washer.

IDAHO.

(Special Correspondence).—F. Augustus Heinze's hand is again seen in a number of mining deals closed the latter part of August, but, of course, the gentleman from Butte makes denial that he is interested in any other than the Stewart property, which he bought some time ago. How-

ever, there are persistent reports and rumors that Heinze's agents have secured options on a number of good things, one of them being the Cooney group in the Cœur d'Alene district, east of Spokane. The Cooney group was at one time bonded to W. A. Clark for \$160,000, but when the first payment became due the Montana senator and his associates passed the deal up. Mark Cooney says that Heinze is after the property. There is also a report that he has a four months' option on the Rex mine, the amount involved being \$400,000. The bond is in the names Fred Kratzer and Charles McKinnis.—Thomas L. Greenough, of Missoula, Mont., president of the Snowstorm Mining Co., announced in Spokane a few days ago that the mine near Mullan, Idaho, east of Spokane, will pay dividends at the rate of at least 20% per year in the future. The question of distributing six cents a share, or \$90,000, this month, he added, is dependent upon whether the dividend can be legally declared after the re-organization of the company.

Increases in the gross value of 65 mining stocks dealt in by the Spokane Brokers' Exchange for the week ended September 1, are placed at \$1,142,375. Rambler-Cariboo heads the list with an increase of \$210,000, Amador being second with \$100,000, and Panhandle Smelter with \$50,000.—The Monument Gold Mining Company, a Missouri incorporation, is doing considerable work at Roosevelt, Idaho, northeast of Spokane. Three shifts are employed and the cross-cut tunnel is now 520 ft. from the portal. It will be driven 200 ft. more to cut the main vein. Joseph M. Venable is manager of the property.

Word has been received in Spokane from Washington, D. C., that the Department of the Interior has ordered the surrender of the patent to the Leonard claim, in the Cœur d'Alene district, issued to E. H. Moffitt, R. K. Neill and C. J. Morse, as the result of a long-standing dispute over the rights of that and the Nilus claims, owned by Dr. D. H. Brien of Spokane. Brien alleged that the surveyor moved the ground lines of the old Leonard north about 600 ft. so as to cover the Nilus claim. Brien is now planning to get a perfect title to the Nilus, upon which he has been keeping up his assessment work.—D. C. Corbin, of Spokane, head of the Spokane International railway, has sold control of the Iron Mask mine, in the Rossland, B. C., district, to the Consolidated Mining & Smelting Co., the price being \$80,000. The mine was located 12 years ago and incorporated by Spokane men, and has paid at an average of \$100,000 a year. The buyers will make extensive improvements and develop the property.

Jay P. Graves, president of the Inland Empire Railway Co., is financing the Holden mine, on Lake Chelan, Wash., west of Spokane, and its owner, J. H. Holden, has put on a large force of men to do extensive development work. It is announced that a smelter will probably be erected to treat the ore.—The Ross mine, near Troy, Idaho, has just sent a car of pure mica to Spokane for treatment. The property is owned by T. A. Williams and his associates. The company has erected a warehouse in Spokane and it is given out that extensive developments will follow.—John Wentworth, president and general manager of the Copper World mine, on Palmer mountain, near Loomis, Wash., received advices in Spokane today that a strike of importance has been made at the bottom of the shaft, the find being of solid sulphide ore. Herome Drumheller and Mr. Wentworth are the chief owners in the mine.

The Federal Mining & Smelting Co., organized by Charles Sweeney, formerly of Spokane, but now of New York, has just declared a dividend of 1½% on preferred, the regular quarterly dividend, and a regular quarterly dividend of 1½% on common, with an extra dividend of 2½% on common, aggregating \$457,250.—The Belcher Mountain railroad, just completed, north of Spokane, has received contracts to handle 500 tons of ore daily from the mines in the Belcher Mountain district.—Ten miles of ditches will be run in the Pierce City district in Idaho, east of Spokane, by C. T. McClintock and his associates, who have just secured control of the Blue Bell, Blue Streak, and the Home groups of placer claims on Muscellshell creek. An elevator will be installed to handle the gravel.

Spokane owners are arranging to install half a dozen concentrating plants in Meteline camp on the lower Pend

d'Oreille river, in Idaho, northeast of Spokane, and the indications are the district which has been idle more than 20 years will resume great activity. C. H. Larsen, mining expert for Peter Larsen, has made contracts for the handling of 300 tons of ore a day, beginning January 1, 1907.—The Dominion Copper Co.'s Idaho mine, north of Spokane, has sent its first five cars of ore to the Trail smelter, controlled by the Canadian Pacific Railway. A new style air-compressor plant of 25 drills capacity is being installed on the Idaho mine.

Spokane, September 3.

SHOSHONE COUNTY.

(Special Correspondence.)—The Frisco mine, at Gem, has resumed operations on September 1 after a long idleness. Gus Ehrenberg is superintendent.—At the Snowstorm mine, near Wallace, it is expected to resume milling soon, under superintendency of W. H. Myers.

Wallace, September 1.

Judge James H. Beatty, of Boise, sitting in the United States Circuit Court, has denied an application for an injunction against the mining companies operating mills in the Coeur d'Alene district against allowing the refuse of their concentrators reaching the waters of the Coeur d'Alene river. The suit was instituted by Timothy M. McCarthy and 60 ranchers owning farms in the valley of the river. It is understood they will take the matter to the United States Circuit Court of Appeals. Judge Beatty declares that to grant the petition would mean to close every mine in the district.

Four more 'tailing' suits have been filed at Wallace, inaugurating another chapter in the litigation resulting from the alleged destruction of land, crops, and animal life below the concentrators by the pollution of the water of the stream by the waste matter from the mills. Of the cases just begun, Josiah and J. S. Hill, of Wardner, jointly have filed two suits, one against the Empire State-Idaho Mining & Developing Co., now owned by the Federal Mining & Smelting Co., praying for \$12,000 damages; and another against the Standard Mining Co., also a Federal property, for \$12,000. In all, they claim to own about 69 acres of land near Kellogg, worth primarily \$200 per acre. They claim the land has been damaged to the extent of \$24,000. The Hills already had similar suits pending against all the mining companies with mills east from Kellogg. The other two suits were filed by Mrs. Mathilde Matheson, who wants \$5,000 from the Empire State-Idaho and also from the Gold Hunter Mining and Smelting Co., of Mullan. The allegations in these cases are similar to those filed in times gone by.

NEVADA.

LINCOLN COUNTY.

(Special Correspondence.)—The prediction of a boom in Searchlight this fall is fast coming true, as is proved by the unusual activity here, due largely to the substantial progress made during the summer in the mines, but the construction of the Barnwell & Searchlight railroad also has had a decided effect. — The Quartette Mining Co. has been paying dividends of \$15,000 per month, which will doubtless be doubled when the 20 additional stamps, now on the ground, are dropping. Two 50,000-gal. tanks have been placed on a high point between the mill and the shaft, and are used for the storage of water pumped from the Drake shaft. One of these will be kept full for fire protection. A fine orebody has been opened on the 800 level. The breast is in 500 ft., and shows a solid face of copper and iron-stained ore that assays \$30 per ton in gold and 10% copper. One hundred feet back from the face the ore for two sets assayed over \$100 per ton. As the orebodies have widened with progress downward and eastward, it is expected that the 800-ft. level will prove better than those above it. — The Annette Mining Co. is enlarging and timbering its shaft to the present depth of 58 ft. The shaft is all in ore, which assays well. Besides copper-stained ore, which is predominant, some galena is found. — The Santa Fe has struck a large body of ore assaying \$20 per ton on the 200-ft. level. The strike was made while driving the north drift on the second level, about 400 ft. in from the shaft. Neither the hanging nor the foot-wall has been found. Apparently a new ore-shoot has been dis-

covered. — A nine-year old boy picked up a 13 oz. gold nugget which the rain had uncovered within 100 ft. of Crescent postoffice. — In the Searchlight Western mine, in cross-cutting on the 150-ft. level, a body of sulphide ore was found assaying from \$4 to \$12 per ton. This is the first time sulphide ore has been found in quantity in this locality. The rock is greenish quartz-porphry. — The Gold Dyke Mining Co., which adjoins the Pompeii on the west, will soon resume active operations. The 103-ft. shaft will be sunk to the 200-ft. level and the property thoroughly exploited. It has a 60-ft. cross-cut passing through a vein 20 ft. wide, from which samples assaying \$2 to \$50 per ton have been taken.

Searchlight, September 1.

NYE COUNTY.

(Special Correspondence.)—From present indications, the Manhattan district will be not only a gold producer, but will also output copper. The Toquima Copper Co., owning property five miles east of Manhattan, is sacking copper ore worth \$100 per ton. Properties adjoining this copper strike are at work, and some with good results. This portion of the Manhattan district is rapidly coming to the front in the production of ore. — Nearer town, the Manhattan Mammoth and Consolidated Manhattan companies are at work on the same gold-bearing veins. The Manhattan Buffalo is working steadily, with the hoist in constant operation, and good ore has rewarded the efforts. — Near at hand, the Consolidated Extension is blocking out orebodies of good grade, and laying aside large amounts of milling ore, awaiting the erection of the custom mill which has been contracted for. Adjoining it, the Manhattan Con. has installed machinery for deep mining. The Mother Lode Co. is driving its adit, opening up a number of ore-shoots that traverse that property. — The Cowboy mine is looking well, and the rich vein encountered in the drift from the shaft is widening. The vein consists of oxidized quartz of reddish color, similar to the ore of the Consolidated, which was rich in gold. — The Manhattan Whale, on a continuation of the Cowboy vein, has a body of milling ore which it is blocking out. — The Union No. 9 of the Manhattan Dexter, and the Little Gray have large bodies of milling ore, and the lessees are doing well, working night and day. — At Central, the Manhattan Nevada Gold Mines Co. is pushing work in the adit on its Georgey group, and have three veins, all carrying gold. A new vein has been encountered in the face of the tunnel, samples from which assay \$20 per ton gold. — On the Manhattan Nemo, adjoining the Georgey on the west, a vein of gold and silver ore was encountered a day or two ago which assays \$100 per ton. This strike was made at a depth of 75 ft. in the shaft. — Specimens of free gold ore have been exhibited from the property of the Manhattan Paymaster Mining Co., three-quarters of a mile northwest from Central. A vein of high-grade ore has been encountered, and the ore is being sacked.

Manhattan, September 1.

The new town of Monarch is 15 miles east of Manhattan, and five miles south of Belmont. Good water is said to be abundant three miles from the camp. Contracts have been let for the construction of numerous stone, brick and frame buildings. The town lies between Belmont and Hunt's canyon, and close to the junction of the Ralston and Monitor valleys. The biggest mining proposition in that region is said to be a dike showing copper, gold, silver and lead.

WHITE PINE COUNTY.

The site for the smelter of the Nevada Con. Copper Co. has been decided upon, a suitable place having been found on Duck creek, 20 miles nearer the main line of the Central Pacific railroad than the mines. On the tract of land selected for this purpose is a large amount of first-class limestone suitable for flux, which partly decided the madagement in its choice of the site. It also gives the company the advantage of a large stream of water necessary in its metallurgical operations.

NEW MEXICO.

Mining conditions throughout New Mexico are excellent, according to the Santa Fe *New Mexican*. The Carpenter district in Sierra county is coming to the front with zinc and

lead. The Magdalena district is now among the big zinc producers of the country. Tres Hermanos district, 25 miles south of Deming, shows considerable development work in zinc properties recently found. There is renewed life near Estey City, in the southeastern part of the Oscura mountains. In the San Andres mountains some copper properties are being developed by Eastern capitalists and are making a good showing. These are in Socorro county. The Lordsburg mining district is shipping from three to five carloads of ore per week. The ores in the Lordsburg district are mostly silicious and heretofore have been costly of treatment. Freight rates on this class of ore to the Douglas and El Paso smelters have been reduced, which has enabled the owners to get to these smelters with their ore and receive higher returns. The promise of the United States Treasury to purchase 100,000 oz. silver per week for coinage will help the silver producing section of Sierra, Grant, and Santa Fe counties.

SOCORRO COUNTY.

The Mine Development Co., with headquarters in Socorro, has purchased the Stonewall Jackson group of mines, in the Magdalena mining district. The group consists of three claims. The ore carries lead and zinc, and development has placed several thousand tons of ore in sight. The Mine Development Co. now has the largest area of mineral land in the district.

SOUTH DAKOTA.

LAWRENCE COUNTY.

The Homestake Co. is now operating 240 stamps on the north end of the property by electric power generated at the new power house, at Englewood, 12 miles distant. The company is preparing to generate electricity at other points. The plant at Englewood utilizes the water pumped over the divide from Spearfish creek. It is piped four miles, and is delivered to the turbines under heavy pressure. The plant has a rated capacity of 600 h.p.—The Minnesota Mines Co., at Maitland three miles west of Deadwood, has commenced the construction of a large cyanide mill, and will increase the working force to complete the plant at the earliest possible date. The company is developing a water supply in Elkhorn gulch, where a dam is being built. It owns an excellent millsite on False Bottom creek, opposite the Maitland mill. After three years of exploration the company has developed sufficient ore to warrant the erection of a mill. The ore is the characteristic quartzite and shale of the district and an extension of the formation which has been profitably explored in the Maitland mine.—It is reported, on good authority, that the Tinton Co., at Nigger Hill, will resume work early in the fall. A payment on the purchase price was due July 1, and the owners granted the company an extension of time. It is said that the company is securing additional acreage and that when work starts it will be on a larger scale than has been attempted heretofore.—J. Welch and associates, who have a lease on the Esmeralda mine in Blacktail gulch, near Deadwood, are meeting with success. The mill is handling 30 tons per day, and as the gold is practically all free-milling, little trouble is experienced in making a good recovery.—J. B. Heath, of Rochford, has bonded his group of mines, near the head of Irish gulch, to Eastern men, who made a part cash payment. There are several veins on the property carrying auriferous mispickel. The property is partly developed. Mr. Heath is in charge of the mines and their development.

The Hidden Treasure Mining Co. is installing machinery at its mine in upper Deadwood gulch, including a gas-engine, compressor, and hoist. The main shaft is down 200 ft.—The Columbus Con. Co., owning a large area north of Central City, which is in line with the northerly extension of the Homestake belt, is negotiating for the property of the Hidden Fortune near the De Smet mine, on the opposite side of Deadwood gulch. The property includes a 60-stamp mill, situated three miles below Deadwood.—The Gilt Edge-Maid mill, in Strawberry gulch, is treating 180 tons of ore per day. Mining is accomplished by the mill-hole and open-cut system. Underground, an electrically-operated hoist is in use sinking a shaft below the adit level. O. P. Ankeny is superintendent.

UTAH.

BEAVER COUNTY.

The Majestic Co. is shipping a carload of copper ore daily from its Old Hickory mine to the United States smelter, netting between \$300 and \$400 per car. From these shipments the company is meeting all its development costs. The management has installed a pump on its Harrington-Hickory property and has resumed the sinking of its shaft.

WASHINGTON.

FERRY COUNTY.

The townsite question of Keller has been settled, and many transfers of lots have been made.—The Umatilla, one mile north of Keller, has put on men under J. King. This property is owned by Spokane and Medical Lake people.—The Gold Cord mine is running a cross-cut from the lower adit to the bottom of a winze in which is three feet of good ore. The cross-cut is in 30 ft. The work is under the direction of W. J. Elmendorf, of Spokane.—The Bridge Creek Mining Co., an Eastern concern, is operating a mile north of the Congress nickel property, on Bridge creek. A cross-cut is being driven to cut the main orebody at a depth of 400 feet.

OKANOGAN COUNTY.

The Twisp River Copper Mining Co. has struck ore in its Index group near Camp Gilbert. The vein is 4 ft. wide.—The Cascade Mining & Milling Co., with a capitalization of \$1,000,000, has been incorporated by James M. Scott et al. to exploit the Cascade group on Sweat creek.—J. C. Harklerode reports striking gold on the Toledo placer claim, where he has expended \$1,200 in ditching and has a large stream which is carried two miles by ditch and flume. Johnson & Robbinette, who have a claim one half mile south of here, have been working all summer. They have 1½ mile of ditch, and work their ground by hydraulic method.

SPOKANE COUNTY.

(Special Correspondence).—Frank MacKean, an engineer in the employ of the Hydro-Electric Co., of Chicago, is in Spokane inspecting the old Spokane smelter, five miles down the Spokane river, with a view to putting it into operation. The property is owned by Scott E. McCrady, of Grand Rapids, Michigan.

Spokane, September 1.

WISCONSIN.

The Mutual Prospect Co., which has had a prospecting drill working near Boscabel, is reported to have struck five feet of solid lead ore at a depth of 20 feet.

CANADA.

BRITISH COLUMBIA.

Following are the shipments for the week: Centre Star, 1,830 tons; Le Roi, 2,280 tons; Le Roi No. 2, 600 tons; White Bear, 220 tons; total for week, 4,930 tons; for year to date, 211,043 tons. At the Trail smelter 6,658 tons of ore were received during the week. In addition to the shipments received from Rossland, ore was sent in as follows: North Star (East Kootenay), 225 tons; Snowstorm (Larsen, Idaho), 101 tons; Iron Mask (Kamloops), 85 tons.

The management of the Hall Mining & Smelting Co., Ltd., states that owing to increase in shipments of ore, and the shortage of labor, it is behind with the unloading of ore, and for some time past have been under considerable expense for demurrage. A few days also are required to make some changes in the sampling mill, which will increase its capacity, and therefore it asks shippers to defer making any further shipments until after the first of September. For the past five weeks the Nelson smelter has undertaken to handle the whole output of the St. Eugene mine, so as to enable the Trail smelter to make some alterations. Very early in the month the big furnace went out of commission and a complete renewal of the crucible was found to be necessary. As a consequence, the storage capacity was exceeded and the sampling and crushing plant was overtaxed.

The winze in the Le Roi mine has reached 1,750 ft., this being the greatest depth attained in the Province. The shaft, which has five compartments, will be sunk further, to 2,000 feet.

Personal.

F. L. BOSQUI is at Denver again.

WILLIAM DE L. BENEDICT is at Oroville.

F. F. Sharpless is in western Chihuahua.

GEORGE P. GOW has returned from Nevada.

W. H. STORMS has been on a visit to Los Angeles.

H. L. LEWIS is on his way from London to Peru.

W. P. NOBLE is on his way from Leadville to Chile.

G. RIOTTE is in charge of opal mines in Queretaro, Mexico.

R. J. MATCHETT left Liverpool on August 16 to go to Tierra del Fuego.

O. H. FAIRCHILD is now manager for the Triangle Mining Co. at Leadville.

H. D. BODDING, from London, is examining mines near Chihuahua, Mexico.

W. E. DEFTY will be in Sonora and Sinaloa until the middle of September.

L. B. DAVENPORT is with the Squaw Creek Mining Co., at Gazelle, California.

CARLOS F. LANDERO, of Pachuca, has been on a visit to Guadalajara, Mexico.

JAMES W. NEILL passed through San Francisco on his return to Salt Lake City.

H. L. JOHNSON is manager of the Oriental Mining Co., near Alleghany, California.

JOHN HAYES is superintendent of the King Con. Mining Co., at Loganville, California.

R. J. FRECHEVILLE passed through San Francisco on his way to London, from Japan.

A. W. MCCUNE is expected in New York on September 20 from Cerro de Pasco, Peru.

W. C. WEST is manager for the Black Peak Gold Mining Co. at Hillsboro, New Mexico.

FRANK G. STEVENS is general manager of the San Pablo Mining Co., in Jalisco, Mexico.

O. E. JAGER is in charge of the blast-furnace plant of the Arizona Smelting Co. at Humboldt.

FRED. J. SIEBERT, on his return from London and Glasgow, has gone to Tonopah, Nevada.

J. A. COOPER has been appointed manager of the Richfield Mining Co. at Tuape, in Sonora, Mexico.

WALLACE BROAD, formerly mining adviser to the Chinese Government, is returning to China and Japan.

JOSEPH LUXON has resigned the superintendency of the Cyprus Noble Mining Co. at Searchlight, Nevada.

W. T. R. COWELL, manager of the Barranca de Cobre mines, has returned to Chihuahua from New York.

FAYETTE A. JONES, of Albuquerque, New Mexico, is examining the placer beds near Cerrillos, New Mexico.

F. X. O'BRIEN, manager of the Homestake mine in Yavapai county, Arizona, is on a visit to Los Angeles.

CHARLES GARVIN has been made general manager for the Green Mountain Mining Co. at Silverton, Colorado.

LOUIS A. CATES, mine manager for the Boston Con. Mining Co., has returned to Bingham, Utah, from the East.

S. A. WORCESTER, of Victor, has returned from doing professional work at Central City and Idaho Springs, Colorado.

NEIL COCHRANE, recently in British Columbia, is now manager of the Jumper mine in Tuolumne county, California.

HORACE A. MORSE, president of the Sovereign Mine Co., in Sierra county, Cal., has returned to the mine from St. Louis.

F. L. BELLAMY has resigned the management of the Mariposa mine, at Taviche, and he is now at Oaxaca, Mexico.

THOMAS J. HENEY, of Spokane, has been appointed foreman of the Tamarack & Chesapeake mine, in Tiger Peak district of Idaho.

EDWARD D. McDERMOTT returned from Japan on the *American Maru* and spent a few days in San Francisco before proceeding to England.

G. A. DENNY has arrived at London. He expects to open an office for consulting practice, having resigned his important position at Johannesburg.

R. P. McLaughlin, formerly engineer for the Standard mine at Brodie and now deputy mineral surveyor at Manhattan, Nevada, is visiting San Francisco.

W. H. WEED, E. O. HOVEY and A. P. COLEMAN were among the adventurous spirits who climbed Colima, and were (according to our sensational daily press) singed by the volcano.

R. D. SALISBURY, professor of geology in Chicago University, spent several days at Alma, Colorado, inspecting the Snowstorm Hydraulic Co. property and will also make a trip to the San Juan before returning to Chicago.

C. H. MACNUTT and E. C. VIGEON have left the Societe des Mines de Cuivre de Catemu, Chile, to take up the management of the Sociedad de Minas de Cobre de Cutter Cove in the Straits of Magellan, in addition to general consulting work.

ROBERT P. MULOCK, of Colfax, Iowa, one of the pioneers of the Lake Superior copper district, is at Calumet, Mich. He was present when the first blast was fired in the Calumet conglomerate by E. J. Hulburt. Mr. Mulock was actively identified with copper mining in Ontonagon county 50 years ago.

Obituary.

JOHN MCQ. FRENCH died at Denver, Colo., on August 29, of appendicitis. At the time of his death Mr. French was local manager for the A. Leschen & Son Rope Co. He had been with the Leschen company about three years. Prior to that time he was engineer with E. K. Smoot on harbor work in Mexico.

Dividends.

On September 6 the BUNKER HILL & SULLIVAN MINING & CONCENTRATING Co. paid dividend No. 108 of \$180,000. This makes the total paid since January 1, 1906, \$1,620,000, and total to date \$7,146,000.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

THE day-fly has better grounds for calling a thunder-storm supernatural, than has man, with his experience of an infinitesimal fraction of duration, to say that the most astonishing event that can be imagined is beyond the scope of natural causes.

SINCE 1851 to the end of March last, Victoria has produced 68,558,132 oz. of gold, valued at \$1,328,853,663. The gold yield for the first quarter of the present year was 190,729 oz., and the dividends paid by mining companies amounted to \$635,563.

OF its yearly production of aluminum, estimated at above 10,000,000 lb., the Pittsburg Reduction Co., apparently exports but little of the metal. During June there was shipped from the United States aluminum valued at \$40,364, bringing the year's total up to \$318,531. Estimating the average price of the metal at 33c. per lb., the exports were only 965,250 pounds.

STEAM FOR ROCK-DRILLS. Where such drills are close to a boiler, steam may well be used, especially where the work is not underground; when the steam is not condensed, it may easily make the workings cloudy. The longest tunnel which has been driven by the use of steam for machine-drills is probably the Magna Charta at Tomichi, Colorado, where the 1.25-in. steam-pipes ran for 3,000 ft. from the boiler to the drills at the face of the tunnel. As the work progresses, the boiler-pressure was gradually raised from 80 to 100 lb. per sq. in., but after 3,000 ft., an air-compressor, driven by water-power, was put in place of the steam installation.

ROLLS make less dust or slime than stamps, and are cheaper in first cost and erection. If ore is to be leached, then crushing by rolls is to be preferred, since it gives a more granular product through which the percolating solutions can pass more readily. If, however, the ore is to be amalgamated this is a matter of less importance, and, on the other hand, gold ore can be more finely crushed by stamps than by rolls. Of late, in cyanide practice, it has been found profitable to stamp the rock coarsely, classify the product into sand for re-grinding, and to save the overflow or slime for direct treatment. In this way the whole product of the mill is so finely comminuted that the extremely fine and intimately distributed gold particles become accessible to the cyanide solution. Such particles could not be recovered by amalgamation at all.

THE first mill on the Homestake lode was a custom-mill of 35 stamps. It stood near the great open-cut in Lead. The first mill erected by the Homestake Co. was one of 80 stamps. This was built in 1878 and was known as the Homestake mill. The Golden Star mill of 120 stamps was built the following year, and the Highland mill of 120 stamps was erected in 1880. The Deadwood mine at Terraville was owned by a separate corporation that built a 60-stamp mill. The Golden Terra, another individual company, also owned a 60-stamp mill at Terraville. These two mines were in later years consolidated as the Deadwood-Terra. The first mill of the Caledonia Co. was situated near Central City, some distance from the mine. In 1880 a 60-stamp mill was built at the mine. The Father De Smet mine was at first equipped with a 10-stamp mill. In 1878-'79 this was replaced by one of 100 stamps. All of these mines and mills are now in-

cluded in the Homestake consolidation. Each of the mills except the De Smet (now Mineral Point) has been enlarged, the six mills now containing 1,000 stamps crush 4,000 tons of ore per 24 hours throughout the year.

REGULAR FEED of ore in a concentrating mill is of supreme importance, since, not only do the machines run better, but they do better work, and produce better concentrate of a more even grade and with less loss in the tailing. Regularity of feed is closely associated with regularity of speed. First of all, therefore, see that the rock-breakers are fed with unvarying regularity, as with them the ore-stream starts. If they are fed intermittently, then the work right through will be intermittent—at one moment the trommels and elevators will be running light, and at another they will be overloaded. This again affects the feed to the jigs, so that they will have at times too much to do, and again too little, and so will be doing poor work. The remedy is to put a careful man at the rock-breaker, and to insist on the principle of feeding—little and often—and you may be sure that it will greatly benefit milling operations.

A CORRESPONDENT writes to say that he is treating, by cyanidation, an ore that contains pyrite in a state of oxidation, and in consequence the cyanide solutions become greatly reduced. His test is to acidify with sulphuric acid and titrate with potassium permanganate.

The reply, prepared by a recognized authority, is as follows:

In solutions acidified with sulphuric acid, potassium permanganate is decolorized by many reducing agents, the reaction being essentially a withdrawal of oxygen from the permanganate acid set free.

In titrating working cyanide solutions the decolorizing effect on permanganate (acid being first added) is as a rule principally due to thiocyanates (sulphocyanides) as KCNS, but may also be caused by ferrocyanides or even sulphides. The relative volume of deci-normal KMnO_4 thus reduced is sometimes taken as a measure of the 'reducing power' of the solution.

Besides the substances usually regarded as reducing agents, there are several compounds which act as oxidizing agents but still have the same effect on permanganate. For instance, it is decolorized in acid solution by hydrogen peroxide, and by substances which yield hydrogen peroxide in addition to acid, such as the peroxides of alkali and alkaline earth metals (Na, Ca, Mg) and percarbonates, perborates, etc. These unstable substances themselves tend to give up oxygen, each atom of which takes another oxygen atom from the permanganate to form a molecule of O_2 .

Permanganate thus gives the most convenient method for estimating oxidizing agents of this class. If, therefore, substances of the peroxide class are added to cyanide solutions before testing the 'reducing power,' the permanganate consumed is due to the combined effect of the oxidizing and reducing agents present, because thiocyanates are practically unaffected by peroxides in dilute alkaline solutions. As a matter of fact a cyanide solution showing a high 'reducing power' by this test is not necessarily in bad condition for working purposes, so long as the effect is not due to sulphide. Excellent extractions may be obtained with solutions containing comparatively large percentages of thiocyanate, provided other conditions are favorable.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

A Point of Law.

The Editor:

Sir—A broker secures an option on a mining property and submits the proposition to a prospective buyer, who sends his engineers to the place for examination and report. The engineers refuse to recommend the purchase on account of terms and conditions, and, with the consent of the broker, take up the matter with the agent of the property direct. In the meantime the option granted the broker expires, but the purchase of the property is consummated. The agent declines to recognize the broker's right to a commission. Has the broker a legal right to a commission? The entire transaction was brought to a close within less than thirty days.

The parties interested by the broker also buy another mine from the agent—one adjoining the mine above referred to. Is the broker entitled to a commission on that?

S. F. M.

Bingham, Utah, August 19, 1906.

We are advised by an authority on the law that: Assuming that the contract in question was a mere privilege given to the so-called broker by the owner of the property within a given time upon specified terms, and not a contract of employment authorizing the broker to sell as the agent of the owner, no obligation rests upon the owner to compensate the party holding the option, for a sale made after the option lapsed, although the purchaser's attention had been originally called to the property by the holder of the option. The measure of the so-called broker's rights is found in this contract or option. As to everything done outside of his contract he was a mere volunteer and cannot claim compensation.

The facts stated do not establish any implied contract on the part of the owner to compensate the holder of the option. Certainly there was no express contract to pay any commission.

To entitle a broker to recover commissions for sale of property he must show employment to sell. The relation of *principal* and *agent* must be established. This relation is fiduciary in its nature. The facts recited clearly show the relationship to have been that of vendor and vendee, where the parties were dealing at arm's length. The option was simply a contract by which the owner of the property agreed that the person who calls himself a 'broker' should have the right to buy at a fixed price within a certain time. He was not a *broker* as to this transaction. He was a 'promoter' or 'option holder' simply. It is quite clear under the facts stated that the so-called 'broker' has no right of action against the owner of the property.—Editor.

As to Foremen.

The Editor:

Sir—This perfect foreman, discussed in your recent issues, often has very difficult problems to solve and it occurs to me that those who know his qualifications would probably be willing to supply a bit of urgently needed advice. Suppose the foreman is unfortunate in choosing his superintendent and finds that the latter has no thorough knowledge of mine-timbering, but thinks he has. Should the foreman insist upon doing his work right and get his time, or should he do as the superintendent thinks right? Which course would prove him perfect?

Suppose the superintendent has a drunken brother in

the mine, should this high-minded foreman keep said brother at the expense of the company, or should he discharge him, at any cost?

We perfect foremen should form a union and compel all superintendents to pass an examination as to their fitness to employ us. It would save us from many such quandaries.

A PERFECT ONE.

Goldfield, Nevada, August 17, 1906.

Mining in Northern California.

The Editor:

Sir—Mining in the northern part of the State offers many advantages to the investor. It is true that many of the veins are low grade, in fact the ore itself is not so valuable as the tailing from mills in other localities, but this is offset by advantages not possessed in other parts. Wood and water are plentiful, and labor is reasonable and of good quality.

The following figures of an actual test under my supervision will give an idea of the possibilities. This test is a six months' run of about 3,000 tons of ore mined by hand labor and crushed in two 2-stamp batteries with concentrators, all run by water-power, and includes all costs—mining, milling, development, etc.; 330 ft. of raises were put up in ore, 150 ft. of drifts in ore, and 300 ft. of drifts in granite. The development alone, which is included in the cost per ton, would probably amount to about \$1 per ton, but this I consider as much the cost of mining as the actual stoping. The vein varied from two to nine feet and would average about four feet. The mill crushed an average of 18 tons per day through a 24-mesh screen for the sulphide ore and through a 30-mesh screen for oxidized ore. The saving with the former ore was satisfactory, considering no means were employed for saving slimed sulphides, while with the oxidized ore the two-stamp mills were most unsatisfactory. Neither stems nor cams were broken and the guides hardly showed signs of wear, although each stamp had dropped over thirty-three million times.

ALGERNON DEL MAR.

Enterprise, Cal., August 18, 1906.

The White Mountains.

The Editor:

Sir—Standing on the peak of Mt. Whitney, you may look eastward over two parallel mountain ranges into Death Valley. Mt. Whitney, the crest of the great Sierra Nevada, has an altitude of 14,502 ft. above sea-level and is the highest point in the United States. Death Valley, 400 ft. below sea-level, is the lowest area of dry land in the United States. Both are in Inyo county, California.

Standing on Whitney's peak a strip of emerald lies 10,000 ft. below you. It follows the eastern base of the Sierras for about 100 miles. It is Owens Valley. Rising abruptly beyond this strip of green is the White Mountain range. This range is approximately 100 miles long and parallels the Sierras on the east. It rises sharply out of the great desert basin from a base altitude of about 4,000 ft. to an average of 8,000 ft; the highest point, White Mountain peak, reaches 11,321 feet.

The north end of the White mountains rises in Esmer-

alda county, Nevada. The range continues southward through the southeast corner of Mono county and nearly the entire length of Inyo county, California, where it terminates. At the southern end lie the once famous lead-silver mines of Cerro Gordo. The products of these mines and the commerce incident thereto were the beginning of the modern city of Los Angeles, California, the nearest supply point. The mines of Cerro Gordo have a record of something over \$17,000,000 in bullion produced.

Remains of ancient arastras and crude smelters used by Mexicans in the '50s and early '60s, are found at intervals in these mountains, proving that those early miners found ore sufficient to invite them to efforts for wealth, with crude methods and slow processes, in a locality barren of food-stuffs, meagre water supplies, far removed from commercial points, out of range of transportation, save by donkeys, and confronted with marauding Indians. Legends of the White mountains abound in recitals of wonderful mines, battles with Indians, suffering, privation, and toils such as are typical of frontier life. Relatively few facts are obtainable. Isolation, privations, and dangers drove away or killed the early prospectors, and the hills, long silent, are now just beginning to echo the song of the invading burro and click of the prospector's pick.

From the railroad now following the valley at its base, the range will certainly arouse the curious attention of miner and geologist. It is a most inviting locality for those who seek for gold. I have been up into what is locally known as the 'gold zone', lying on the western slope and near the base of that range, at a few points. Recent developments, at various localities, beginning at Buena Vista in Esmeralda county, Nevada, on this western slope, and as far southward as Black Canyon, about 40 miles, verify some of the legendary tales of properties that can be made profitable. Gratifying success is rewarding modern systems of development, and these White mountains ought to be exploited by men who know how.

FRANK DRAKE.

Bishop, Cal., August 12, 1906.

Who Is a Mining Engineer?

The Editor:

Sir—To me it seems you have raised a rather delicate question—delicate, because of the disposition on the part of some of the profession to form a sort of exclusive set, the members of which hold themselves aloof from others who are their peers in every respect. I am not giving consideration to those imposters who, having memorized a few technical words and phrases from text-books, write what they call 'reports' on mines, and sign 'mining engineer' after their names.

That those constituting the 'smart set' among mining engineers have any reason to consider themselves superior in any way to the balance of the profession is not in every case apparent to the careful observer, for there are among them some of the most notorious pretenders—men who have achieved no success, earned no honor, or in any manner accomplished anything that would, in the minds of competent judges, stamp them as being entitled to more than ordinary consideration. There is a certain class of engineers who look with disdain upon all others of the profession not in their set, regardless of their qualifications or actual accomplishments—they are outside the sacred circle, and consequently tabooed. The mention of the name of one of these is met with a cynical smile or the contemptuous shrug, on the part of the elect. But are these, the '400' of the profession, the most competent to judge "who is a mining engineer?"

When a man graduates from a mining college and

receives the degree of E. M. or M. E., as the case may be, he is certainly entitled to be recognized as a mining engineer, even though he be neither eminently successful nor prominent in the profession. This may be due in part to his lack of better opportunities. There are young men of my acquaintance who have graduated with high honors; they are successful, in a way, but not noted. In college they were not prominent in fraternities, giving more attention to their studies than to the social life of the college town—so, in the after days, they are not noted as mining engineers. I know other young men who were in the same classes with the first mentioned. They were foremost in fraternity life, but passed their ex's by the 'skin of their teeth,' with the aid of much coaching, and these young men, almost without exception, hold positions of trust, honor—and big salary. There are exceptions, however, to both of these. Not infrequently young engineers attract attention to themselves early after graduation by writing of their work, and they are called to take responsible positions with commensurate salary attachment.

But what of the non-graduate engineer? There are men who stand high in the profession, men who have forced their way upward from the ranks, and who are now prominent because of their practical knowledge and large experience. They know what the college man knows, but know it more thoroughly—as the college man will know it later on, when he has had the practical experience. The object of the college training is to lay a foundation for the experience of the future. The student simply goes to the point by a less circuitous route. Science is organized knowledge. The experience of generations in the past has been carefully collated, the best has been adopted and this is taught in the colleges, so that in the four years of the college course the student has the principles of his profession drilled into him. His practical experience during the college years is limited to a few weeks each summer in actual mining or metallurgical work, but after graduation he advances rapidly.

The mining engineer, to be competent, must have large experience in many things. He must understand geology, particularly that branch of the science dealing with ore deposits and their genesis. He must have had experience in the drilling and blasting of rocks; in transportation; and with the various kinds of power—water, steam, gas engines and electricity. He must have knowledge of metallurgy and of engineering, and the problem of handling men is not the least of those requiring his careful consideration. Above all these he must possess, in an eminent degree, good judgment—more often called common sense. In my opinion the man having these qualifications is entitled to be considered a mining engineer, whether he has had the advantage of academic training or has acquired them in the hard school of practical experience, though none will doubt that where the two are found combined the best results may usually be found.

AN ENGINEER.

Los Angeles, August 21, 1906.

UP to velocities of air-current of 400 ft. per minute the speed of the current may be measured in a drift of uniform area as follows: The operator walks along the drift at a uniform rate, and for a measured distance, carrying a candle at such a speed that the flame shall burn in an upright position without being deflected from the vertical, either by the current or by the progress of the person carrying it. The time in seconds to traverse the known distance is determined by a watch, and the average of several trials used. Let us take, for example, the distance as 300 ft., the time as 70 seconds, and the dimensions of the gallery $5\frac{1}{2}$ ft. high by 6 ft. wide. We then have $60 \times 300 \times 5\frac{1}{2} \times 6 = 8,485$ cu. ft. per minute.

Breckenridge, Colorado.

Written for the MINING AND SCIENTIFIC PRESS
By JAMES W. NEILL.

Breckenridge lies in the valley of the Blue river, some forty odd miles from Leadville, on the line of the South Park railway, and the trip thither is one to be remembered for its scenery. The little train winds around the cliffs, climbs the Fremont pass and fairly rattles down the steep grades past Kokomo, Robinson and Dillon; then up the little valley to Breckenridge. There are mines all along the route, some past, some present, and some future, as is evident from the surface works, dumps, old metallurgical plants and the like; all these only add details

The stand-pipes of the elevator system, which is in duplicate, are seen on the left of the upper print; the lift-pipes are 12 in. diam. and the water-pipes about 10 in. The main supply-pipe is seen on the top of the bank just to the right of the elevators; this brings the water from several miles up the canyon under a head of several hundred feet, and gives not only the elevator water but also the pressure for the monitors that break down the gravel. One of these is seen in the foreground playing on the bank, and the force can be realized from the fact that the nozzle is six inches in diameter, and throws the stream 200 ft. to the top of the 60-ft. bank. The photograph was taken at noon, hence no men are seen, and the nozzle is quiet.

Hydraulicking and Elevating.

to the interest of the trip, and the main thought as one flies down that canyon is, "I wonder how big the trout are in that hole?"

Breckenridge has long been the centre of placer mining activity, and it was to see some of this that my visit was made. Of principal interest to me was the work being done

From being simply a funnel-shaped pit with the elevators at the centre, the operation is extended by the giants as they wash the gravel down into the bedrock flume which leads to the foot of the elevator pipes; this ditch is seen in the photograph directly behind the giant, and looks something like a pipe leading to it. Down

Disposal of Tailing by Conveyor-Belt.

close to town by the Gold Pan Company; this is an 'elevator plant,' that is, the gravel is moved from the pit by means of hydraulic elevators; a jet of water from a large nozzle is directed into the bottom of a pipe of large diameter, and by the energy of this stream of water large stones, and much additional water, are raised to the necessary height. The accompanying photographs show this plant in some detail. The first one shows the pit which is the mine. This pit is sunk to bedrock, in this case about 60 ft.; to say this is easy, but to do it is a hard task! This work is being done in the bed of the Blue river, which had first to be turned aside and carried past the locality in a big flume, on high trestles, in places over the edge of the pit. Then the bedrock water or natural seepage has to be pumped and the material handled, the sides supported, the boulders taken care of; and all this without the aid of the elevators, for these cannot be installed till the pit is made.

this flume the smaller gravel and rock is washed and raised by the water into the sluices above, where it gives up its precious values to the riffles and quicksilver; the water falls through a screen or grizzly, and the rock is dumped onto the foot of a traveling belt, and this carries it up and finally dumps it at a considerable distance and height from the pit.

The apparatus just described is shown in the second photograph, which, on the left, shows the outer end of the sluices, then the dump where the water is wasted, and the sand goes away down stream, then the steep incline of the first rubber belt, and this in turn dumps onto the final rubber-belt carrier which takes the rock to the dump. This material is naturally only of a size that will pass through the pipes, everything larger than this has to be handled from the pit by means of traveling locomotive-cranes, seen in the first photograph on each side of the cut. These cranes handle the rock on boats,

onto which it is loaded by hand, and it is necessary for a man to go to the dump each time to unhook one chain, so that it will dump. What with four men to load boats, one to run the locomotive, and the time used to dump and return, etc., this seemed to me to be an expensive method of handling rock. The right foreground of the first photograph shows the size of some of the boulders, and the necessity for some powerful agent to remove them. Naturally, while the pit was being sunk, and the first start made on the opening, there was no place below for the storage of the big rock, and this was at that time taken out by means of a ropeway of the Lidgerwood type and dumped on the other side of the creek, not shown in the photograph at all. It seemed to me that

tions either present or future. The ground is claimed to be very rich, and from the outlay which has been made and the evident cost of the operation, I should say that it must be, to yield a profit. I do not know how else such a deposit as this can be worked; dredging is out of the question, the size of the boulders precludes this, and even drift-mining would probably be impossible owing to the large amount of bedrock water, and to the nature of the gravel; so that this method, improved by better mechanical and executive methods, would appear to be "the only way."

The "other way" is illustrated in the next two photographs, one showing the operation of a Keystone drill, prospecting for gold or rather testing the gravel of a

Prospecting for Gold-Bearing Gravel With a Keystone Drill.

some mechanical scoop or bucket operated by cables could be used here in place of the many men, and these only help to hook on the largest rock.

The bedrock seemed very flat, and as the flume or sluice has to keep on it, this too was at a grade on which even the large amount of water did not move the larger cob-

ble known placer. The mill-men are just dumping the sand-pump, the contents of which are being caught in a pan by the chief, whilst a visitor makes notes on the side, and the panner washes the material obtained in the previous pumping. The rocker, in the middle foreground, is used to clean up all the material taken from the drill-

Dredging for Gold at Breckenridge.

bles, so that one or, at times, two men were constantly moving up and down this sluice, helping the cobbles along with shovel—which also seems an expensive operation.

I could not readily make even a guess as to the yardage handled, and the operations were in fact not on a regular basis, as the flume which carries the creek around the pit had broken a short time before, filling the pit with water and gravel, and they were only just getting down to regular work again. The capacity of the elevator to handle water can be judged from the fact that when the flume was repaired, and the elevators started to pump out the pit, which was full and running over, it took just four hours to finish and get to the bottom.

The plant is equipped with tremendous machine shops, out of all apparent proportion to the needs of the opera-

tion, and the tailing from this rocker falls into a box, and is thus measured, so as to make comparison with the theoretical contents of the drill-hole. The nature of the material is indicated by the pile of rock on the right, taken from an old elevator-pit or incline sunk years ago. This is in the valley of the Swan, and in the distance is seen the tailing dump of a dredge-boat.

The last photograph is of a dredge (the Reliance) working on one of the tributaries of the Blue, about three miles from Breckenridge. It is a steam-driven sluicing boat, having 8 cu. ft. buckets open-connected, and though digging in hard ground and bringing up many good-sized boulders, it is evidently doing good work and plenty of it. The gold in this district is coarse, much of it in wires and small nuggets, and the sluices save this, or nearly all of it in the first few riffles, the undercurrents on the tail-barge yielding very little.

A Note on the Rhodesian Gold-Mining Law.

Written for the MINING AND SCIENTIFIC PRESS
By THEO. F. VAN WAGENEN.

The following story is told of an Australian miner who came to Rhodesia last year to try his luck. He was a good man of his class, and landed at Beira with a few odd pounds and shillings in his pocket, and at once took the train for the hills. When Umtali was reached, and he found himself, to his delight, once more under the shadow of the Union Jack, the appearance of the country so pleased him that he got off the train and, after a day in town, he bought himself a pick and shovel and pan, loaded them, together with some *scoff*, or 'grub,' on a donkey, and started off on a prospecting tour. In a couple of weeks or so he came back, and inquired his way to one of the banks. Arrived there, he drew from his pocket a buckskin bag, and passed it over to the teller with the request that the gold be weighed, and its value in sovereigns be given in exchange. When the contents of the little sack were poured on the scales, there were about twenty ounces of very nice-looking alluvial gold in the pile.

"Prime-looking stuff," said the teller. "What is the number of your claim?"

"Oh, I have no claim yet," replied the Australian. "I just washed that out while prospecting."

"We must have a claim number to declare it by," said the teller, with a rather suspicious look in his face.

"Why," said the miner, "it's nobody's business but my own. Do you think I stole it?" he added, while a little red spot showed on each cheek.

"Oh, no," returned the teller, suavely, but edging off a little; "that's all right, but we must report to the Government where it came from, or we will get into trouble."

"What's the Government got to do with the matter, anyway?" returned the Australian—"I found the place and dug the gold out. It took a week of hard work too, and I had a touch of this damned fever I hear of. There is more of the stuff, I guess. If there is a royalty, take it out. And take out your charges, too. I'm willing to pay for coin, and I'll paint this sleepy town of yours a bright crimson before morning. But I'll see the Government in Hades with its back broke before I'll tell where I got it. Why, half the loafers in town would follow me out there and jump the ground before I could peg it. Does the Government think I'm a fool?"

"Sorry," said the teller, "but we can't buy it. Against the law. Nice gold, too. Just what the country wants to put some life into it." And he passed the little yellow pile back to the miner. "Better go and see the mining commissioner," he added, "he will fix you up."

"Yes, and maybe he'll attach all the gold, and chuck me in the cooler besides," said the Australian, disgustedly.

"Oh, no," returned the banker, "he will treat you all right. Better go and see him."

"Maybe," said the miner, as he gathered the bags into his pocket and turned to the door. He was hungry, very much in need of some new togs after his long tramp, and out in the street were a dozen or so of black 'boys' waiting for their pay. The situation was complicated, and not at all pleasant.

Across the road was a general store, to which he went, and, having laid his pile of nuggets on the counter, he asked to have them weighed, so he could buy some clothes, adding that he "would take the balance in coin and notes."

"We don't buy gold," said the proprietor, "and I wouldn't know how to figure it up anyway. But the bank will buy it of you. Nice gold! Where did you get it?"

"I don't see that that's anybody's business but my own," retorted the miner. "I haven't asked you where you got these goods you want to sell me, or whether you paid for them. What kind of a hell of a country is this anyway? Don't you want to get rid of your merchandise? Why don't you get a little pair of scales, and learn how to buy gold? There's money in it, and you're dead safe, and you'll sell your stuff besides."

"Couldn't possibly afford it," said the shopkeeper. "A license costs £20, and there wouldn't be two customers of your kind in a twelve months. Why, man, I've been here for nine years and this is the first time I've seen any real gold. I never thought you got it that way. Always supposed it came out of a stamp-mill, and in little white balls about the size of an apple."

"The suff'ring Moses!" ejaculated the Australian. "I supposed this was a mining country—and it *is* one, only you people don't know it. Say, will you take the gold over to the bank and sell it for me?"

"Certainly," said the other, "but you will have to come along and sign the declaration. What's the number of your registration certificate?"

"Certificate be hanged," said the miner. "Haven't got any yet. I've only been out prospecting. Maybe the ground ain't worth pegging. It took me a week to wash out this, and I want to prospect up and down the gulch a bit before I locate. What's the use of taking up the worst patch when the best one hasn't yet been found? Do the miners of this country peg out ground before they have tested it?"

"Well," said the friendly shopkeeper, "to tell the truth, I don't know how they do it, and more, I don't believe there's a real prospector in the country. I've never seen one, or heard of one. There's lots of engineers and managers and secretaries, and other such cattle, but they don't seem to know much about mining, judging by the way things come out at most of the mines. But say, if you haven't got a claim you had better get one, or else go and put that gold back where you got it, or get it off your hands some way, or it will get you into trouble."

"What's the matter with *you* taking it?" said the Australian. "It's gold all right. You take it and give me a suit of clothes and a pair of shoes, and enough coin to pay these niggers outside, and some cash to go on. I'll be liberal. There's more where that came from. Don't you want to do business? I haven't stolen it. There's money for you in the deal, and you can work it off. You know the ropes."

"I daren't," replied the merchant. "It would get me into all kinds of difficulty. No, I think you are all right, and I'd like to sell you what you want, but it's too risky. Say, you go up to the mining commissioner. He'll fix you all right some way. First-rate chap." And, going to the door, he pointed the way.

"I suppose I'll have to," said the miner; "but I never struck just this kind of a lay-out before. Why, it's worse than the way they do things in Siberia."

Up the almost silent street he went in the direction indicated, and, having found the Mines Office, he stated to the clerk that he had some gold and wanted to declare it, and transform it into money. And he poured out the glittering grains on the counter.

"We don't buy it here," said the clerk, "but all you have to do is to fill out this blank and swear to it, and the bank will take it off your hands. Nice little pile of stuff," he added, and, stepping to the door, he called the attention of his chief to the matter. The latter came out of his office and looked over the pile interestedly. Meantime, the Australian had been studying the blank to see what he had to swear to. "Where did it come from?" said the commissioner, finally.

"About 60 miles out to the northwest," responded the miner. "But say, Mr. Commissioner," he added, "I can't fill out and swear to this. I've got no claim pegged out. I've just been prospecting. I've got some promising ground, but not good enough to peg out yet. So I want to sell this, and pay my boys, and get some clothes and a new jag of *skoff*, and go back and do some more work."

"Haven't you pegged off your ground yet?"

"No, of course not. I'm only prospecting so far. There's only a little patch where I got this, but I guess there's plenty more near by. But I don't want to peg where I've been working. I want to find the main body, and get enough good ground to make it worth while. There's no sense in taking up a little streak off the main channel. I want to get enough to make a mine. You see, some of the bars along the gulch are no good, and some are patchy, and I'm after a full claim."

"H'm," said the commissioner, "I see. That's good common sense. We must fix you up someway. Here," to one of the clerks, "make out a discovery and registration notice. Now, my friend, here's the way you do it. You put up the discovery notice—no, you first put up a peg where you got the gold; then, say 20 ft. away, you put up another, and put the discovery notice on it, and make a copy of it. Then you wait a few hours, or a day if convenient, and then put up the registration notice, and make a copy of that, and mind you be careful about putting the date and hour of the day on both. Then you put up your claim pegs, four of them. Then come in here and bring your copies, and we'll fix up your papers. You'll have to swear to the copies and make a little sketch plan of the block and the country around it, so we can tell where your ground is, and then an affidavit that you are going to work the ground for gold, and then you pay in a five-shilling stamp, and we give you a registration certificate, and you go out there and put the number of it on beacons on your corner pegs. Then, when you come back, you can fill out this gold-declaration properly and swear to it. You've been working a little irregular, you know, but that's all right. You must have some ground before you can sell your gold, so we may know where the stuff comes from. And, oh, by the way, I forgot, you'll have to turn in your license and give it up when you register, but you can buy another one. They only cost a pound."

"What's the number of the license?" said the clerk, who was filling out the papers.

"Haven't got any license," growled the prospector. "Do you take me for a millionaire?"

"The devil!" said the mining commissioner: "That's bad. You must have a license to prospect." To the clerk—"Make out a license for him. Cost you 20 shillings, my friend—and lucky to get off at that, for you've been breaking the law, but that's all right. You didn't understand the rules, and I wish we had a lot more of you Australians out here."

"Hold on," said the prospector to the clerk, "hold on! You're going a little too swift for me. I've got no quid* for that license. Look at those boots, will you? I've tramped 200 miles in them already. Now you say I've got to go out to the ground and put up my pegs and notices, and then come in and get a number, and go out again and put that number on the beacons, and then come in and sign all these papers, and put up five shillings more. That's 240 miles more of walking, and a month's work, and then I can sell the gold, and then you'll take the prospecting license out of it, eh?"

"Well," said the official, "that isn't quite regular, but you leave the gold here and we'll take the chances on

you. And, oh, I forgot—you'll have to pay a pound a month claim license besides, and you'd better just leave about three months' license money with us before you go, so as to be safe, and if you think you are likely to want to peg out any more ground, you had better take out a half-dozen licenses; they will always come in handy."

The Australian was rubbing his chin and thinking. "Say, Mr. Commissioner," he said finally, "you're a square man and a good friend, and this is God's own country surely, and I'm a bloody law-breaker and ought to be in chains. Now I want to show you I am grateful. That's a neat little pile of gold, eh? About twenty ounces in it. Ought to be worth about seventy quid. It's 200 miles to Beira, isn't it? Yes. And I owe those niggers out there just £8.15. And third-class fare from Beira to Melbourne is £14. I'll have to take to the boat, as the swim is a little too long. Now, *you* take that gold and pay the boys, and give me twenty quid. And *you* go out and peg that ground. It's awful rich—gold just everywhere. I'll hit the trail for Beira. It will be a saving of 40 miles in the walk. *You* take the ground, and pay the licenses, and the 5s.-stamp, and the claim-license, and be happy. Take my blessing. The altitude's too high here to suit my health. It gives me a pain. You make a clean 30 quid on the deal and get the ground besides. Ain't that fair?"

When last seen the Australian was climbing into a train at the station, that was headed eastward. He had a new suit of clothes on, and looked happy. How it was accomplished no one will ever know. But there was a young fellow at the platform, bidding him good-bye, who had just handed him a ticket to Melbourne, and a dozen yellow boys with King Edward's face upon them, good the world over for anything that money will buy; and as the train slowly moved away, the tall Australian wrung the youngster's hand and said:

"Say, kid, the chief's all right. He got me out of a bad corner and I'm grateful. If anyone from the office ever shows up in my camp, you bet he'll be treated white. But say, you tell the old man that if he ever hears of a prospector coming this way again, he ought to tell the mayor to call out the brass band and all the sporting clubs and secret societies, and meet him at the station, and present him with the freedom of the country, for it will pay big. Good-bye."

COLOMBIA is rich in minerals, says a consular report. There is an immense coal supply in Colombia. It is found in many different parts of the Republic, including the neighborhood of Cali in the Cauca and near the Atlantic coast. There is much soft or bituminous coal in the mountains around Bogota. Gold is mined in the States of Antioquia, Tolima and Santander in paying quantities. Silver is found in Antioquia, Cauca and Tolima; copper in Boyaca, Antioquia, Cauca and Tolima; emeralds in Boyaca; platinum in Choco; petroleum in Tolima; while lime, chalk, marble, asphalt, lead and quicksilver are found in many parts of the country.

PLATINUM has been found in the copper ores of the Rambler mine, near Encampment, in Wyoming. It occurs there in the form of sperrylite, the arsenide of platinum, and is associated with covellite, the monosulphide of copper. Chromite is another mineral which is likely to carry platinum in association. The platinum of the placer mines of northern California is always accompanied by osmium, a rare metal for which a use has lately been found in the manufacture of the Auer incandescent light. This will render the platinum mining industry more profitable.

SCIENCE is nothing but trained and organized common sense.

* Colloquial English for *cl.*

Cyanide Practice With the Moore Filter.---II.

Written for the MINING AND SCIENTIFIC PRESS
By R. GILMAN BROWN.

So little has been published concerning the Moore process that no excuse is needed for explaining it, with as much minuteness as is possible in the absence of notes and working drawings.

The points in common between the Moore and the Cassell-Butters process are: The filtration by vacuum, with the resulting adhesion of the cake to the outside of the

filter or 'plate' is a 3/4-in. channel-iron (*RR*) that serves as a launder for the in-filtered solution. The filters are stitched through both sides vertically at four-inch distances and in the compartments thus formed 1/4 by 1 in. strips are inserted to allow circulation. Within each filter a 1-in. vertical suction-pipe, flattened at the end so as to dip into the channel-iron launder, reaches to the bottom from the outside. The outer end of this is connected by a short length of suction-hose to a three-inch manifold, through which the suction is applied. The

Fig. 1.

filter; and the general type of filter, which allows of great area in compact and cheap form. It seems to me that the point of adhesion of slime to the filter, making possible its removal from the remaining pulp, is the real point of difference between these and other slime methods. Others in plenty have filtered by suction, others have used parallel closely spaced units to secure maximum area in

details of this will be better understood by reference to Fig. 1: *A* is one of the vertical suction-pipes, *B* the manifold in end-view and *A*¹ and *B*¹ the plenum-pipes and manifolds. In the Standard Co.'s plant there are 49 of these 'plates' hung from a frame of steel I-beams (*EEE*, *FFF*), the distance between centres being four inches. This constitutes the 'basket,' approximately 16 f.

Fig. 2.

minimum volume, but so far as I know the adhesion of a cake to the outside of a filter and its removal by this means from the unfiltered pulp is the essential novelty with which the Moore process should justly be credited, in practice, at least. The essential difference between the Moore and the Cassell-Butters method may be considered an inversion of the Mountain-Mahomet theorem; Moore transfers the filters, with their load of slime, by means of a traveling crane from the pulp to the wash-water tank and then to the discharge hopper, while the Cassell-Butters plan removes the pulp from the filters by pumps of large volume, substitutes wash-water and then discharges, the operation being conducted in the same vat.

In the Standard Co.'s plant the filters are of canvas of medium weight, 5 ft. wide and 16 ft. long; the canvas is double, sewed round three edges, and the fourth (long) edge is bolted between slips of Oregon fir (*Q Q*, Fig. 1) 1 1/2

square. On the top of this rests a suction-pump (*C*) 12 by 12 in. driven by a 10-h.p. D. C. motor (*D*), which derives its current from the crane overhead. With a vacuum of 20 in. the motor consumes 3 h.p. of current, but in the early part of the cycle when filtering is fast, there is a heavy rise in power at the end of the stroke due to expelling solution from the slender clearance space. To equalize this the pumps have heavy fly-wheels. Clearly this basket arrangement lends itself to great area of filtering surface, there being 7,840 sq. ft. concentrated in each unit. The basket is hung by four endless one-inch pitch-chains to the overhead crane and is raised or lowered by a 10-h.p. motor (*G*) through the medium of balanced worm gearing and differential chain-wheels. The driving pulley on the motor is indicated at *H* and the driven pulley at *I*, on the worm shaft *J*; *KK* are the worm-wheels, keyed on the shafts of the pocket-wheels *MM*. These

worm-gears are right and left thread. The worms bear on collars on the ends of the worm-shaft and the direction of rotation is such that, raising the load, puts shaft *J* in tension; at the same time the worms being right and left, there is practically no end-thrust on the bearings. The pocket-wheels are of six and seven pockets respectively. The crane-motor and pump-motor get current from the trolley-wires *VV* through the forks and wheels *O O*; *P* is

manner of the Koepe hoist, the main sheave being driven by a worm-gear from the main-line shaft. A grip on the crane engages the cable and the gear is started, stopped and reversed by a belt shifter through the medium of levers conveniently placed for operation by the basket-man. The tail-sheave is on a carriage and adjustable to take up stretch of the cable. The rate of travel is five feet per minute. Fig. 2 shows the general plan of the filtering-vats and the discharge-hoppers. The filtering-vats (which, along with the others, belonged to the former sand-plant) are round, flat-bottomed vats 24 ft. diam. by 7 ft. deep. They have four-armed agitators (Fig. 1) running at 7 r. p. m. close to the bottom. The shaft to which these are attached is driven by crown-gearing below the tank. A special stuffing-box devised to keep the sand out of the bearing has proved satisfactory, but could be improved upon. In addition to the agitators, each filtering vat is fitted with two six-inch air-lifts discharging onto two distributing launders on the tops of the baskets. These are run intermittently during the accretion period and serve to bring the coarser particles to the surface, whence, as they slowly settle, they are caught by the suction currents and deposited on the filter with the slime.

The action of the filtering process is as follows: The basket is lowered into the vat full of pulp, until the tops of the slats are submerged, and the suction pump is started. The first solution coming through muddy is turned back into the vat. It soon clears, however, unless

the insulated rest onto which the trolley-wire drops, when not held up by the wheel *O*. The crane-motor is operated through the starting-box *T*, which is controlled from the tank-floor by the cords *U*. The total maximum load of the full basket on the crane is 35 tons and this is raised about seven feet in five minutes. This represents about 3 h.p. The motor consumes 8.4 h.p. of current, so that the loss, even with the balancing of the worms, is heavy. Still, as the hoist is in operation not above one hour per day, this is negligible. Notwithstanding the differential gearing was furnished by specialists, it gave trouble at first, largely because the pockets in the wheels were not deep enough or well fitted to the chain. Even now when this has been overcome, guide-wheels that were devised to make the chain grip the pockets better are retained as a measure of precaution. Probably any future design should have wheels with twice the number of pockets. The general construction of the crane is clearly indicated by Fig. 1 and the photographs, and needs no explanation. The pocket-wheels are placed at quarter-span points of the large I-beams, and all stress calculations were for a factor of safety of five. The supporting track is of 60-lb. T-rail and rests on heavy 12 by 18 in. longitudinal sills, the caps of the supporting sets. To prevent spreading of track, the sets are framed back to the main posts of the building. All of this construction could well be of structural steel where transportation cost is not prohibitive. The traversing device for the crane is a $\frac{5}{8}$ -in. plough-steel wire-cable, run over three and four-grooved sheaves, after the

of the slats are submerged, and the suction pump is started. The first solution coming through muddy is turned back into the vat. It soon clears, however, unless

Moore Filter, With Cake.

End View of Moore Filter-Basket.

a filter leaks. Should there be a leak, the identity of the faulty filter is quickly established by an inspection of the glass nipples connecting each individual 'plate' with the manifold, and that plate is cut out by closing the proper service cocks in the manifolds. Suction is continued with intermittent agitation until a sufficient coat is obtained, which in this case averages $\frac{3}{4}$ in.; then the basket is raised, the suction-pump still running, and

traversed, with its load of slime adhering, over the wash-water tank and lowered therein. Here suction is continued with frequent titration of the filtrate toward the end, till the solution has fallen to the predetermined minimum net strength of cyanide. The displacement is good, about 0.7 ton wash-water being needed per ton of dry slime; the cake in this condition carries about 40% moisture, so that every ton of slime is accompanied by 0.67 ton solution. The limiting net cyanide content of the filtrate is the difference between that in the wash-water, which always contains a little that has been soaked off from previous charges, and that of the filtrate. This is in the neighborhood of 0.15 lb. per ton or 0.0075 per cent.

After washing, the basket is raised again and run over the discharge-hopper; the suction is continued till excess moisture is removed and then an air-pressure of 35 lb. is turned on, in successive blasts of a few seconds each. This causes the cakes of slime to drop off, the discharge averaging about 85% of completeness. Every alternate day the filters are cleansed by substituting water, under 20-lb. pressure, for air. On each basket there are two special air-manifolds connecting with the inside of each filter, at points four feet from the ends. Probably these could be omitted, and the vacuum manifold be used for the plenum as well. The discharged sludge averages 68% solids and is sluiced from the hoppers into the waste-flume, about a ton of water being used for each ton of slime. The grade of flume for this class of material is $\frac{1}{16}$ in. per ft. The time consumed in a single cycle depends primarily upon the thickness of the pulp; as an instance, a pulp of 20% solids will scarcely build up a one-half inch coating in 10 hr., while pulp of 40% solids will give an inch coating in two to three hours. The average thickness for last year was 0.74 in. and the maximum for any one month 1.14 in. The time of the accretion period is about three and one-half hours; washing and discharging take the same, making about three full cycles in 24 hr. with time for emergency matters. This is considerably longer than is the experience elsewhere and must be attributed to the large proportion of clay in the material. During one month, when clay was notably less, the average fell to 2.35 hr. for accretion and 2.9 hr. for washing and discharge. The average load handled in each cycle is close to 18 tons of dry slime, so that the two units in this plant have an average capacity of 108 tons per diem. This has not been obtained in practice over any extended period, but the limiting factor has not been the filtering, so that the monthly capacity of the plant has been conservatively placed at 3,000 tons per month. Fifty-eight per cent of the total solution recovered from the plant has come through the filters. Beyond this point the process is the same as in any cyanide plant except that the sump solutions, after being standardized in storage-tanks, are returned by a three-plunger pump to the mill.

Taking up some of the details not yet touched upon, the following is to be noted: The question of the wear of the filters is an important one. An extreme life of 10 months has been noted in some cases, but, if badly made or carelessly handled, they require constant attention, repairs, and renewals; half a cycle per day can easily be lost in this way. Six months can be taken as a fair average life; this, at a monthly tonnage of 1,500 per basket, makes the cost 5c. per ton. In other plants where smaller filters are used, the canvas is stretched on an internal frame of pipe and so kept taut, the pipe, at the same time, serving for suction and discharge-pressure. In the Standard plant no trouble has been experienced from letting the filters take their natural hang, and when the plant was being designed, the stretching of the canvas over a frame did not appeal to us, both because of added

expense of construction and of shorter life of the canvas, which would be under greater tension when the 'plates' distend under air-pressure and become distorted. Whether the latter is a valid objection, only unbiased comparative work can tell. The individual 'plates' are spaced one from the other by light wooden rods to which their edges are attached by twine. There are four of these, spacing the ends of the 'plates' at middle and lower corners. As a certain amount of slime gets through the filter at times (when a leak develops when the basket man is not at hand), the solution passes from the pump through a launder first to a clarifying-tank from which it is decanted to the gold-tanks. An addition, recently installed as an improvement on this, is a permanent set of 'plates' in the clarifying-vat, through which the solution is drawn. This device is used elsewhere with success.

From tailing averaging about \$8 per ton the average return has been 83% of the gold and silver, the gold alone being close to 90%. Higher results have been at times attained, and the indications are that the average for the present year will tend to approach these figures. The total extraction from the ore is as given herewith; the third column gives the results for a \$20 ore, this being about the average for the mine:

	Per cent of product.	Per cent of crude ore.	Value.
Recovery in the mill.....	54	54	\$10.80
Recovery in the slime plant.....	83	38.2	7.64
Total recovery		92.2	\$18.44

Comparing this with the old method by percolation, we have the following:

			Value.
Recovery in the mill.....	64	64	\$12.80
Recovery in the cyanide plant.....	70	25.2	5.04
Total recovery.....		89.2	\$17.84

This gain of 3% or 60 cents per ton is small and hardly more than enough to cover the extra cost which on the basis of work during last fall is 22c., so that it does not furnish a strong argument for fine grinding in cases where the whole product is amenable to percolation. But so far as this ore goes, and many like it, the comparison is by no means fair. Under the former method of treatment 30% of the tailing was left in the ponds, being unfit for any but slime methods. The revised comparison then would be as follows:

	Percentage of product.	Percentage of crude ore.	Value.
Old method.			
Recovered in the mill.....	64	64	\$12.80
Discharged from the mill.....	36	36	7.20
Left in the ponds.....	30	10.8	2.16
Going to cyanide plant.....	70	25.2	5.04
Saved in cyanide plant.....	70	17.6	3.52
Total saving.....		81.6	\$16.32

This shows a gain of \$2.12 per ton, ignoring any difference in cost. In our work last fall this came to \$0.22 increase, so that the net gain is \$1.90 per ton. Roughly, the plant cost \$60,000, though it could probably be duplicated for one-fourth less, so that on the basis of the tonnage of 20,000 per year the gain represents 63% return per annum on the actual cost of the plant, fully justifying the investment. In addition to this gain is the ability to treat some 40,000 tons of accumulated slime, which has thus become an asset. The above comparison is on the figures of cost actually attained; using the cost of \$2, estimated for the future, the gain would be \$2.37 per ton.

The following table gives the segregation of cost for the various departments:

General expense, including superintendence, watchman, assays, insurance, taxes, chemicals, supplies, etc.....	\$1.202
Re-grinding	0.572
Moore process.....	0.314
Zinc room.....	0.261

Total in slime-plant.....	\$2.349
Ponds, collecting and handling, with team.....	0.120

Grand total.....\$2.469

By the disc-harrow percolation method, formerly fol-

lowed, the cost was \$2.25. This figure of \$2.47 is for a restricted tonnage, and careful estimate on a basis of 3,000 tons per month brings the cost down to \$2. Future work should improve even on this. Mention has been made of the accumulated tailing. This material has been made available for immediate treatment by the provision of a stock-bin outside the grinding-house. It is connected on the one side with the ponds by an inclined track and a stationary hauling system and on the other with the tube-mill by a steep launder, into which the tailing is fed from the bin, mechanically. In the case of ore of this kind with qualities of very slow settling, the addition of dry material is a decided advantage to the plant, as it increases the percentage of solids and lessens the time of settling. It is probable that this outside stuff, not having participated in the violent agitation with cyanide solution accomplished in the mortars, and moreover only coming into contact with the solution that reaches the tube-mill already weakened from its original strength of two pounds by the 'cyanicides' in the ore, does not yield as highly, and so cuts down the average extraction pro rata.

To the experienced cyanide man a question naturally presents itself as to the accumulation of weak solution. The addition to the bulk of solution comes from moisture in the ore and from the wash-water, the losses from evaporation and leakage and from the discharged tailing. On the basis of the dry ton, the additions are $0.09 \text{ ton} + 0.7 = 0.79$, while the determinable losses are 0.47 ton. This indicates an increase that is not found in practice. But if it were, the extreme weakness of the solution would make such a gain not of first moment. Just how the difference is to be accounted for, is not clear, but it is due in part at least to the difficulty of correctly determining the moisture in the discharge.

For years the concentrate has been treated in a pan, with a lye and bluestone charge, giving results that were only satisfactory because no way had appeared of bettering them. Soon after the slime-plant had been put in operation, the experiment was tried of treating the concentrate with strong cyanide solution, and with such good results that the method completely supplanted the old. The details are as follows: The concentrate consists largely of iron oxides with a little pyrite. This is charged in one-ton lots into an ordinary five-foot silver pan, 25 lb. lime is added and enough water to bring the pulp to about 45% solids, giving the consistency of thick cream. The charge is ground for 48 hr. and then cyanide is introduced, to bring the solution up to a strength of 24 lb. per ton. Grinding is continued with the addition of lime and cyanide at intervals, the one to insure alkalinity and the other to keep up the strength to the original. After about 72 hr. it passes to the settler for 24 hr. further agitation and finally is diluted with mill solution and turned into the slime-plant flume. Toward the end of the operation, samples of the pulp are taken at intervals, washed clean of solution and assayed, as a check upon the extraction.

An interesting feature is that during the grinding with lime, an oxidizing action—a sort of wet roast—appears to take place, the pulp changing from a dirty green to a brownish red. The results of this work for some 30 tons—one half the year's product—with an assay-value of over \$150 per ton, are: Extraction of gold, 96.8%; of silver, 84.1%; total, 94.9%; the cost is \$7.91 per ton. The consumption of cyanide is 18 to 20 lb. per ton. An excellent comparison of the new and the old method is obtained by considering the work of the first half of the year, which was by pan amalgamation: Extraction of gold, 87.1%; of silver, 74.9%; total, 84.4%; cost, \$13.38 per ton. On \$150 con-

centrate the gain per ton amounts to \$15.75 in extraction and \$5.47 in cost, a total of \$21.22.

To the advocate of fine grinding the results I have given may appeal with too great force. Stamping, if followed at all, must almost of necessity be in solution, and the low cyanide content demanded by more than one factor is apt to give low results as regards the silver. In an ore which, by reason of absence of coarse gold, will yield creditably to cyanide alone, amalgamation can be dispensed with and probably less solution used. But it is doubtful if even then a solution strong enough for good silver extraction could be used without excessive loss. Certainly, however, in ore of the Standard type fine grinding gives higher results for the same cyanide strength, and the same extraction for a lower strength. Between the two there is intermediate strength that gives the maximum commercial result, and in all tests with fine grinding the aim must be to determine this point. As a comparison between the general Moore-Cassel-Butters method and filter pressing, it seems that the former has great inherent advantages in cheapness of installation and operation, and growing familiarity with the details should make this increasingly evident. In comparison with decantation, apart from the fact that for some ore decantation is entirely unsuited, it does away with the enormous bulk of solutions, from the repeated washings. In fine, it is believed that once metallurgists become better informed on the principles of the system, it will be found worthy of more consideration than heretofore.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

The ore from Miramar, Cal., marked W.L.B., is lead-carbonate in a granular siliceous rock.

The white rock from Gibbonsville, Idaho, marked J.W.O., is not Feldspar but Baryta (barium-sulphate).

The minerals from Paisley, Ore., marked G.G., are: The white, Kaolinized feldspar; the black, manganese oxide.

The rock specimen from Goldfield, Nev., marked L, is a much altered rock, seemingly originally granitic. The bright, metallic sealy mineral is Specular-iron (hematite).

The rock samples from New Pine Creek, Ore., marked W.E.M., are determined as follows: The hard pink colored rock is felsite, the color being due to iron oxide. It may carry gold, in which case there is probably auriferous pyrite in the rock, though none is observed in the sample sent. The soft white mineral is Kaolin, which on moistening with water becomes plastic like putty. It may also carry gold or silver.

The rocks from O'Neals, Madera county, Cal., marked M.C., are various phases of a much altered granitic rock. The white mineral is Kaolin with much secondary mica (sericite). The firmer piece still shows the granular structure of the original rock. The rounded lumps are of the same origin, but are impregnated with the white iron sulphide, marcasite. Any of the rocks may be, and probably are, auriferous. The alteration is due to crushing and shearing of the rock along a plane of faulting, and the subsequent oxidation of its individual constituents, together with the infiltration of iron sulphide.

A Hydraulic Mine in California.

Written for the MINING AND SCIENTIFIC PRESS
By D'ARCY WEATHERS.

The Spring Valley mine is situated at Cherokee, about seven miles due north from Oroville in Butte county, California. It is one of the few hydraulic mines still in active operation, having partly survived the disastrous effect of the wholesale enjoining of such work by the litigation that followed the 'debris agitation' in the early '80s. It is, however, but a shadow of its former self—from a miner's view-point.

Discovered by the Argonauts in the greatest prospecting expedition the world has ever witnessed, the deposit was worked by pan, rocker, and sluice, by individual

The headwaters of the Big Butte creek and the west branch of the Feather river gave the supply and the ditch system aggregated 52 miles, the average width was 5 ft., and the depth 3½ feet.

The duty of a miner's inch is the quantity of material that one inch of water (1.5 cu. ft. per min.) is capable of moving; it varies with the quantity of water, pressure, character of material washed, grade and width of sluices. The duty at Cherokee was reported to be 5.5 cu. yd., but the average duty at large hydraulic mines did not run over three cubic yards.

Originally this was one of the largest hydraulic mines in the State, and for 25 years employed between 200 and 250 men. At times it is said to have had 10 monitors at work throwing streams of seven-inch diameter. The

Fig. 4. Method of Blasting.

Fig. 3. Auger and Gun for Block-holing.

locators up to the year 1858, when hydraulic work, then in its infancy in California, commenced. This continued unbrokenly until 1879, when litigation interfered with further progress. Up to 1870 the water supply consisted

bank was in places 500 ft. high, and it was not unusual for the debris, in caving, to bury the monitors and pipes 400 ft. away.

The bedrock is largely slate with veins of diorite cours-

Fig. 1. Section of the Cherokee Channel.

solely of the drainage from a surrounding territory of about 110 square miles. In that year there was installed a supply system, the plans for which were decided by the engineers of that period. How successful they proved, will be related. Reservoirs were built, ditches constructed, and a pipe-line of wrought iron, 30 in. diam. and 13,100 ft. long, was laid. In inverted siphon shape, it crossed the deep gorge of the Feather river's west fork, the perpendicular depression below grade being 902 ft. This pipe furnished 2,210 in. of water per 24 hours during eight months in the year. To secure a yearly supply, additional reservoirs and ditches were constructed three years later, and another pipe-line 34 in. diam. and 3,780 ft. long was added to the first. This also included an inverted siphon, the vertical drop of which was 630 ft. The greatest thickness of the piping was 0.375 in., at a point where the pressure equaled 384 lb. per sq. in.

ing through it. This is covered with a layer of 'blue gravel,' varying in thickness from 10 to 50 ft. and consisting of cemented gravel and boulders which require blasting before washing. The 'blue gravel' was overlaid by what has been thought to be a separate flow, and is a layer of boulders from 3 to 15 ft. thick. Above this is a more valuable stratum which contained from \$1 to \$8 per yard; it is overlaid by layers of pipe-clay mingled with fine white quartz sand. The channel, which was at first only about 500 ft. wide, is at the present face nearly 1,000 ft. in width. By 1890, 4,800 linear feet of it had been worked. This included 150 acres, worked from surface down to bedrock (a thickness of about 500 ft.), and a like amount worked from the surface to within 15 ft. of bedrock—the hard cemented gravel being left in position. It is estimated that up to 1870 \$5,000,000 in gold had been produced. From that date to 1886 there was

\$5,008,208 extracted; while mining expenditures, including land purchased for tailing ground, impounding dams, building reservoirs, debris canals, etc., was \$1,862,244, and the cost of mining and caring for ditches, etc., was \$1,759,953. The mine during all this period worked day and night, two 8,000 c.p. electric lights being used by night.

The tailing flowed through a canal 32 miles long, to two restraining dams 1,800 ft. wide, covering 12,000 acres of the land. Those intimately connected with the past working of the mine differ as to the further course of the channel, though in a general way the continuation under Table Mountain is known. Litigation, commencing about 1879, tied up the mine for many years, and the final sale of the water-power to the Spring Valley Water Company crippled its output immensely.

Fig. 1 is a sectional view showing the condition observed today, and Fig. 2 shows the present face of the bank. The grade of the bottom as shown in Fig. 1 is 4.5 in 100, steeper than the average inclination of these ancient channels, and this factor combined with its great width suggests the mighty torrent that must have flowed here in the geologic period that saw the advent of man. A section of the working face as exposed today, with the amount of gold contained in the several strata, is given below, commencing at the top of the bank and reading down to bedrock :

Material.	Thickness in feet	Value per cu. yd.
*Basaltic lava.....	80 to 100 in places
Reddish pipe clay with layers of white quartz sand.....	325
Yellowish sand with a little clay.....	90	80.17
†Rotten boulder lead.....	5 to 10	\$1.50 to \$2.50
Light blue gravel.....	0 to 5
Bluish cemented ground.....	25	80.50
Sandy, blue, cemented gravel.....	5 to 30
Total, not including basalt.....	465	\$2.67

* Very little of this interferes with the working, as it is chiefly to the south of the channel.
† This is the stratum mentioned before as being the richest, and receives its name from the brown discoloration due to the oxidation of pyrite.

At this point therefore the average value is less than two cents per cubic yard.

Only the natural drainage is now available, and, with the pipe installation that still obtains, this should supply water for at least six months in the year. During the past season, however, the mine was worked for about

are broken by 'block-holing' or 'bulldozing.' Fig. 3 shows the auger and 'gun' used in this process. About ten boxes of Judson powder (50 lb. each) are used in this work. For the rock or cemented gravel, giant powder is required.

At long intervals—generally once or more during a

Fig. 2. Face of the Gravel Deposit.

season—'bank blasting' is resorted to, to assist in caving a large mass of material for sluicing. The last blast took place over a year ago and was done in the dry season, and in the following manner: An adit (Fig. 4) was driven for 115 ft. into the pipe-clay at a height of over 100 ft. above the bedrock—and a drift made each way from the end, the length of the drift being 77 ft. At the ends of the drift, chambers were excavated 15 ft. long and in these were placed five or six tons of Judson powder, these charges being fired by electricity. The dotted line shows the ground caved by the blast. It is proposed during the coming autumn to explode a blast of between 45 and 50 tons of dynamite. Only about 12 to 16 men are employed at the mine at present.

The gravel is sluiced down a cut in the bedrock, followed by 100 ft. of box-sluice paved with boulders and containing mercury, and then down an inclined shaft 125 ft. to the main drainage tunnel, which is 3,400 ft. long and cut through the rock. From here the flow enters a ravine and follows it down to the tule lands and im-

Fig. 5. Seven-inch Monitor at the Spring Valley Hydraulic Mine.

eight months due to the erratic and protracted rainfall through the State. Three monitors with 7-in. nozzle are in use, but not more than two are operated at once. The pipe-clay in the bank, referred to before, in caving often forms large lumps, which, when over 2 ft. diam.,

pounding dam mentioned before. The rock-tunnel contains a six-foot wooden flume paved with boulders and an undercurrent 24 ft. long and 20 ft. wide is placed near the end; the grade of the sluices is 6 in 16; 1,200 lb. mercury are used during the season, at the end of which the clean-up takes place. At several times during the history of the mine, notably when troubled by litigation relating to the debris problem, it has been suggested that it be worked by the drift system, and surveys have been made for that purpose. This proposition has again been brought up, and it is said that a tunnel 1,500 ft. long will reach the 'rotten boulder' lead in the channel, from the side of the ravine and through the rim-rock. As shown by sketch, the channel, if following on its present course and grade, would (at a point $1\frac{1}{4}$ miles down stream from its present face) lie at a depth of 265 ft. below the surface. Until this and the question of whether the gold content continues, have been proved by drilling or shaft sinking, the value of the scheme remains in the realm of conjecture.

RUSTING OF IRON AND STEEL.—There are three important differences between iron and steel which ought to cause a difference in their rapidity of rusting: First, blow-holes; second, manganese; and, third, the presence of cementite in the steel and of cinder in the wrought iron. Blow-holes exist in steel, but not in wrought iron. But blow-holes, at least those which do not weld up and thus cease to exist, are not necessary. Yet they are to be prevented only by care and skill. Hence, get your steel only from careful and trustworthy makers. Manganese steel always and almost necessarily contains more manganese than wrought iron. This may or may not hasten its rusting. If it does, then its effects ought to be made manifest even in short time tests, but tests do not show that steel rusts materially faster than wrought iron. Steel is generally richer than wrought iron in cementite, the iron carbide. Wrought iron always contains much more cinder than does steel. Of the two, the cinder of wrought iron ought to gain more than the cementite of the steel in its value as a 'mechanical retarder of corrosion as time goes on and more and more of the metal is eaten away. The reason for this is that the cementite is in such minute microscopic plates that the eating away of a small quantity of the steel from above them ought to bring very nearly the full proportion of this cementite to the surface; whereas, the much larger and more distantly scattered plates of cinder in wrought iron would not constitute their full share of the surface until a much thicker layer of initially overlying metal had been eaten away. This, then, may be the true explanation—that is, the reason why steel does not rust faster than wrought iron in our direct tests though it does in actual use—that our direct tests are too short to bring out the full protective action of the cinder of the wrought iron. Or the reverse may be true. As time goes on the harmful effect of the difference of potential of the cinder may grow more than its protective action. Let us, therefore, henceforth push our tests to destruction.—*Industrial World*.

AIR MAINS.—Pipes supplying air to rock-drills should be of a size to permit the passage of air at a velocity not greater than 25 to 30 ft. per sec., while all bends and angles (especially short ones) should be avoided, as they add greatly to the friction of the air, and thus decrease the pressure. The friction of the air is proportional directly to the length of the pipe, and to the square of its velocity. For this service, pipes up to 5 in. diameter are provided with couplings, above that with flanged joints made up with gaskets. Great care must be taken that these joints are perfectly tight, as the loss, even from a pin-hole, is considerable.

The Huntington Mill.

In the Huntington mill a special principle is brought into play. The rolls are suspended vertically from their revolving frame or head, and crush by their centrifugal force as they roll upon the steel ring forming the outer circumference of the mill. For many years the Huntington has been in use as a competitor to stamps, and lately it has been largely introduced for re-grinding the coarse tailing in concentrating mills. It is claimed for it, that:

- (1.) The cost of the same capacity is not more than one-half that of stamps.
- (2.) Freight to the mill where it is to be erected, one-fourth that of stamps.
- (3.) Cost of erection, one-tenth that of stamps.
- (4.) It runs with but one-third the power per ton of ore crushed.
- (5.) The wear is less than with stamps. This follows as a corollary from 4.
- (6.) The wearing parts are easily duplicated.
- (7.) The discharge is freer and more effective, leaving the pulp in better condition for concentrating.
- (8.) It is also a better amalgamator, nine-tenths of the gold being caught inside the mill, the balance being saved upon plates in the usual manner.
- (9.) Simplicity of construction, so that less mechanical skill is needed.
- (10.) Crushing action is continuous.

The Huntington mill is best suited to pieces of one-half inch and less in size and the feed should be regular. One difference between it and stamps is that the centrifugal motion throws outward against the crushing ring the heavier portions of the ore, whereas in the stamp-mortar the lighter and smaller particles of the ore are the ones which intervene between the crushing surfaces of the shoe and die. Again, the mercury is not beaten or pounded between the grinding surfaces and thus it is but little floured. The mercury, it will be remembered, is carried as a layer or pool upon the bottom of the pan. The crushed product, coming through the screens, is more granular than with stamps and hence (and this for re-grinding is one of the greatest arguments in its favor) is better suited to concentration.

When working upon ordinary gold-quartz the capacity of a 6-ft. mill in 24 hours is 30 tons with 55 rev. per min., taking 8 h.p. to run it. This is for partly crushed material one-half inch and less in size, and crushing through about No. 3 sheet metal screen (one millimetre wide).

LANGUAGE looks rather to *de facto* than to *de jure*. In our aim to keep language stable and conservative, we may justly oppose changes introduced by the careless into the meaning of words; but, when we try to undo changes which have already occurred, our task is often hopeless. Then instead of being the conservers we ourselves are the changers. Indeed, unless the advantage to be gained is great, it is doubtful whether an attempt to reverse a change, which is already established, is justifiable. This is especially true when the change which we would reverse is a natural expansion, growing out of the development of our conceptions and of our knowledge.—H. M. Howe in *The Metallographist*.

THE first stamp-mill in Alaska was erected in Silver Bow basin in 1883, and shortly afterwards John Treadwell built a five-stamp testing mill on the Paris creek lode and organized the Treadwell Mining Co. In 1884 the company erected its first large mill of 120 stamps. Since then operations have been increased, and now there are in operation, or in course of construction, in the vicinity of Juneau and Silver Bow basin 1,500 stamps.—*Douglas Island News*.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

SAFETY DEVICE FOR MINE-CAGES.—No. 825,334 ; Charles Mulhearn, Freeland, Pennsylvania.

In a safety mechanism for elevators, members having rack-teeth, a platform moveable relative to said rack members, trip-arms swinging laterally and moving toward and away from said platform and adapted to engage said rack-teeth, coupling means between said trip-arms and platform, and a weight associated with said trip-arms and operating to maintain them normally spaced from the platform.

COMBINED SCREEN SIZING AND JIGGING AP- PARATUS FOR ORES.—No. 826,178 ; George O. Marrs, Walker, Arizona.

In a combined apparatus for jigging and size-screening, comprising a series of jigging-compartments provided with horizontal perforated partitions and a series of screens and at a higher level than said partitions, each screen being arranged to receive the overs from one compartment and to deliver the finer material to the next compartment in the series while conveying the coarser material away from said compartment.

STAMP-MILL.—No. 826,726 ; John Hunt and Charles A. Hunt, Los Angeles, California.

In a stamp-mill, a horizontally-revoluble cam-wheel ; wedge-shaped cams upon the upper surface thereof ; a ver- tically-movable stamp having stems projecting upwardly therefrom and passing in close proximity to the periphery of the cam-wheel ; tappets rigidly secured to said stems of the said cam-wheel and adapted to be engaged and lifted and revolved and dropped by the cams on the cam-wheel, said tappets having a ball-race in the bottom of each ; and balls in said ball-race.

BALL-BEARING FOR HYDRAULIC GIANTS.—No. 826,931 ; Morris L. Gordon, Seiad Valley, California.

An improved hydraulic giant having in combination a pipe-section provided with an annular flange, a nozzle-sec- tion having an annular flange about its base, a packing-annulus interposed between said flanges, said annulus having radial recesses, bolts extending between the flange of the pipe-section and the annulus, nuts fitted to the bolts and located in the radial recesses of the annulus, a wearing- ring secured in the nozzle-section and underreaching the annulus, a packing between the annulus and flange of the nozzle-section and antifriction-rollers between said annulus and the wearing-ring.

MINER'S TOOL.—No. 826,569 ; Ole Hanson, Mercur, Utah.

A pocket-knife having an end portion of the back-spring extended and terminating in a spring crimper member, a second crimper member co-operating therewith, means for actuating the second crimper member, and means whereby said actuating means is adapted to force the first crimper member toward the second crimper member.

DREDGING-MACHINE.—No. 826,993 ; Louis Coiseau, Paris, France.

Suction dredging-machine having a vane-wheel bearing on the surface which is required to be dredged, a half-drum in which the vane-wheel is rotatably mounted, a suction- pipe, a pump or an ejector connected to the upper part of the suction-pipe, an orifice provided in one of the cheeks of this drum, for receiving the lower end of the suction-pipe, and an adjustable opening provided in the other cheek of the drum opposite to the suction-orifice.

A New Air-Compressor.

The accompanying engraving illustrates a new type of Sullivan air-compressor, which is particularly suited to the requirements of mines and quarries, as well as for industrial purposes of various kinds. This machine is of the duplex pattern, and is built in several combinations of steam and air cylinders, also for belt and power drive. The dominant feature is the box frame, with housing, which forms a tight enclosure about the crank-discs, main bearings, eccentrics, connecting rods and cross-heads. This housing excludes dust and dirt, and permits the use of a system of self-lubrication of the principal working parts. As shown in the sectional view, an oil well is provided in each frame, in which the lower edges of the crank-discs are immersed. The oil clinging to the discs is removed by scrapers in contact with their upper edges, and thence conveyed, by means of a storage chamber and suitable pipes, to the main journals, crank-pins, eccentrics and cross-head guides, being finally returned to the well by gravity, to be used again. These machines require the minimum of attention and care, as it is necessary to add oil to the wells only at long intervals.

These compressors are compactly and substantially built.

motion, but at the points of opening and closing of the valves, these points attain their greatest speed; it is thus possible for the valves to remain open during the entire stroke, allowing the cylinder to fill with air at barometric pressure, and trapping it instantly before the piston begins its return. The valves themselves are made of close-grained semi-steel, of large diameter, fitted with accuracy. Provision is made to permit a thin film of air to get behind the closed valve, pressing the cutting edges to the seat, and making the valve tight against leakage. The valve-stems have T-shaped heads on their inner ends, carefully planed and fitted to the slots in the ends of the valve. The attachment is such that the valves are free to follow up wear automatically without hindrance from the stems. These valves may be removed through the back bonnets without disturbing the setting of the valves. These compressors are made by the Sullivan Machinery Co., of Chicago.

Commercial Paragraphs.

THE CHAPMAN SMELTING WORKS Co., formerly of San Francisco, are now permanently located at 625 Myrtle St., Oakland, Cal. They are in the market for buying and

A New Sullivan Air-Compressor.

All sizes, except those of largest capacity, are mounted on a heavy sub-base, in which the inter-cooler and steam re-heater (on cross-compound machines) are situated. The frames are of the heavy duty type or Tangye pattern, with long bearings on the base, securing rigidity, and maintenance of correct alignment of working parts. The steam valve-gear is controlled by a Meyer adjustable cut-off, the throttle being regulated by a sensitive steam and air governor. The air-cylinders are not cored out, but instead, separate liners are forced into the castings, thus precluding shrinkage strains. The space between the liner and the cylinder forms the water-jacket, and outside of this again is the air-inlet passage. Incoming air is thus admitted to the cylinder without contact with heated walls. The air-cylinder heads are also water-jacketed, and in two-stage compressors an efficient inter-cooler is provided, consisting of a nest of cold-water tubes, made of copper, with whose cold surfaces the air is forced to come into intimate contact in passing from the low to the high-pressure cylinder.

The inlet valves on all air-cylinders are of the semi-rotary or Corliss type, and are moved by steel valve-stems, connected by adjustable connecting rods to independent eccentrics on the engine-shaft. The moving parts start from, and arrive at, the ends of their travel with a slow and easy

treating antimony ore, for which they offer prompt cash settlement.

THE ATLAS ENGINE WORKS, of Indianapolis, whose Chicago sales offices have been in 900-902 Fisher Bldg., will, upon completion of the new Fisher Bldg., increase their present quarters by the addition of several large offices.

THE tube-mill manufactured by the COLORADO IRON WORKS Co., of Denver, Colorado, is especially designed for fine-grinding of ores in cyanide solution. The Dorr classifier, also manufactured and sold by this concern, is adapted to the separation of flocculent slimes from the purely silicious material. The tube-mill not only effects fine pulverization, but brings every minute particle of material into direct contact with the solution and affords all the aeration necessary. This company also manufactures grinding-pans for fine-grinding in connection with cyanide treatment or amalgamation. One of these pans was recently installed in a Homestake mill, in the Black Hills, South Dakota.

Editorial.

THE AMERICAN MINING CONGRESS is to meet at Denver on October 16 and to remain in session four days. A special effort is to be made to kill dishonest mining finance, and to that end a strong committee has been selected to draft a bill, which, it is hoped, will become a law.

IT IS STATED that ore so rich in copper glance or chalcocite as to contain 50 to 65 per cent copper is being mined on the 2,400-ft. level of the High Ore mine, at Butte. This ore is sacked for shipment to the Anaconda smelter and it is stated to come from a vein nearly six feet wide. Apart from its economic importance as a fact indicating the persistence of rich veins of copper to a maximum depth, it is interesting as indicative of a zone of secondary enrichment so deep as to oppose the idea that such re-deposition is necessarily of small extent. While these workings in Montana are only half as deep as those in Michigan, it must be remembered that in the latter case the copper occurs native in a bed of conglomerate, while in the former the metal is found as a sulphide, precipitated from the descending waters that have leached the lodes at a higher geological level.

WASTEFUL METHODS in mining are often due to the richness of the ore, they represent an extravagance unrestrained by necessity. When, however, an engineer lectures on waste in a region of low-grade ore such as the Rand, we take it that the lack of strict economy becomes an extravagance because it is multiplied by an enormous tonnage. The thoughtful remarks of Mr. Sidney Jennings will prove suggestive, not only to those in charge of mines at Johannesburg, but also to managers of mines elsewhere. In order to be economical, it is necessary to know what others are doing, for the manager of a single mine or group of mines is not likely to be able to arrive at the best result in each department by his own initiative. Comparison of ideas and borrowing of experience are more effective than individual experiment. In this regard the Rand has been fortunate, for not only have the mines under a single management profited from the work done at the different members of a group of properties, but the capitalists in control have encouraged the engineers to visit other regions where particular problems had already been met in the course of mining practice.

THAT PROSTITUTION of modern journalism, the Hearst newspaper, is becoming unpopular among Americans in Mexico because of the anxiety created by the wild stories printed in the 'Morning Screams' and the 'Evening Howls,' from New York to San Francisco. A mining engineer telegraphed to us a couple of days ago to state

that the reports as to trouble at Cananea were false. There are about 200 soldiers quartered in the various camps of that region—Cananea, Ronquillo, and Chivatera—not to mention the heavily armed police. No outbreak is expected and there is no reason to anticipate any at present. By their reckless tales of impending revolution, the Hearst papers spread distress among thousands of American homes, the bread-winners of which are engaged in mining in Mexico. Incidentally W. R. Hearst is benefiting the telegraph companies—people against whom those of us who live in San Francisco still feel resentment for their meanness during the days of the earthquake-fire. Thousands of telegrams are prompted by the yarns concerning trouble in Mexico, such despatches voicing the anxiety of those at home and conveying the assurance of those abroad. To punish the total disregard of decency on the part of the journals mentioned, many Americans—quite independently of their political affiliations—have discontinued their subscriptions. If, in addition, the respectable local papers of the country would forbear re-printing Mr. Hearst's balderdash, there might be a hope of stopping such criminal foolishness.

On Writing Clearly.

On another page we publish a lengthy extract from a pamphlet giving suggestions to authors of papers on economic geology, prepared by Mr. S. F. Emmons, for the United States Geological Survey. While intended for a special purpose, it will be of obvious use to a wider circle of writers and among others to mining engineers, not only in the writing of articles, but in preparing reports on mines. As Mr. Emmons says, "the writer should keep constantly in mind the fact that the primary object is to present to the reader a clear picture of the region described rather than to give an exposition of the mental processes by which his results have been obtained." This is well said, as is also the advice that "direct, simple statement of facts is more to be desired than rounded periods, rhetorical flourishes, or studied originality of expression." Another injunction is worth quoting: "The writer should bear in mind that an economic report is intended for readers who are not necessarily technical geologists, and he should therefore avoid, as far as possible, technical words with which they are not likely to be familiar. When the use of such words is unavoidable their meaning should be explained in parenthesis or footnote." This applies directly to those who make reports on mines; with many engineers there seems to be an idea that profundity, not to say obscurity, is impressive; and we confess that there is reason to believe that some investors appear to like a report couched in terms unintelligible to them because they think it emphasizes the highly scientific training of their technical advisor. However, such simpletons are becoming scarce, and the day is near when directness and clearness of expression will be understood to be the sign of clear thinking and thorough knowledge of the subject in hand. Meanwhile, it is well for the officers of the Survey to set an example; among the writings published by this department of the

Government there are many publications needlessly verbose and painfully burdened with uncommon terms. Such matter fails to fulfill its primary purpose, which is to give useful information to the public. And if this criticism is made, it is with the thorough appreciation of the fact also that among the reports and bulletins issued from the office of the Survey are a number of treatises and descriptions in economic geology so carefully prepared and so lucidly written that they stand as models in the literature of applied science.

Scarcity of Labor.

From the older mining towns of California there comes a plaint that workmen are scarce, and this scarcity is imputed to the building operations in progress at San Francisco, San Jose, and Santa Rosa. But in the cities on the Bay there is urgent need for more workmen. It is stated also that many of the men who have long worked in the mines of the Mother Lode have been attracted by the opportunities offered to prospectors in Nevada. But in Nevada also there is a demand for more miners than are available. From Michigan we learn that the copper mines need more laborers and that the lumber companies are perplexed by the shortage of woodsmen. The same complaint comes from the iron mines of the northern country. James J. Hill states publicly at St. Paul that despite an immigration of 1,000,000 people per annum, labor outside the cities was never as scarce or wages as high as at the present time. Bisbee, Cananea, and other copper mining centres of the Southwest are in want of men. Without going into further detail, it can be said that similar conditions obtain all over the West and in parts of the East. There is a general scarcity of labor in the United States. Nor is this the only country thus affected; we know that as regards mining there is a labor famine in South Africa and in Mexico. Is this condition to become aggravated?

It is apparent that the industrial activity of the United States is calling for an increased supply of labor, in order to complete works already undertaken. The demand exceeds the supply, partly by reason of the expansion of industry and partly because the hours of labor are shorter. Working days of ten or twelve hours are becoming almost universally replaced by the eight-hour day and, it must be confessed, without an equivalent improvement in the quality of the service rendered. Where a thousand men did a certain amount of work in a thousand working days, we now need nearly 1,500 men to achieve the same result. The shorter hours and the consequent increasing cost of labor have prompted mechanical invention, whereby a machine with one or two skilled men does the work formerly done by a great many unintelligent laborers. Save for the help obtained from machinery, the situation would be even more acute. But if industry progresses and the working population does not increase proportionately, while slowly tending toward a universal eight-hour day, what is to be the outcome? In Nature and in Art there is a principle of compensation, the tendency of which is to correct all excesses. The inevitable result will be a period of industrial depression.

By the Way.

In a recent issue of *Science* there appears an authoritative and suggestive article on 'The Nature and Origin of Volcanic Heat' by Professor Elihu Thompson. He says:

The hypothesis of a molten or more or less fluid interior, as possessed by the earth, may now be said to have been abandoned, and along with it the supposition that volcanoes constitute vents for the escape, as a consequence of shrinkage and subsidence, of a portion of the molten content lying everywhere under the solid crust. The hypothesis that the interior of the earth, while in the main solid, has cavities containing melted matter which occasionally is forced out in the form of eruptive outbursts, is a kindred one which has found some adherents. But a truly solid interior seems to be demanded by the accepted great rigidity of the body of the earth, and Mallet has put forward the idea that extraordinary pressures exerted to crush the rocks would result in their becoming heated and melted. Evidently, however, mere pressure acting alone, however great, would not suffice for this. Incipient fluidity would substantially put an end to the crushing process and heat generation would stop. The observed high temperatures attained by volcanic products during eruption would not be reached. More recently the thermal effects of volcanoes, and the various results thereof, have been ascribed by one authority to the presence of radium, which, as is known, continuously gives out energy in its breaking up. But volcanic lavas have not been found to be sources of radium or of uranium, the amount of which should be quite large if the supposition is to be given any serious consideration.

The object of this paper is to present a view of the origin of volcanic heat which may possess some elements of novelty and, it is hoped, of rationality. According to this view, much of the heat manifested is due to mechanical work converted into heat—a theory based upon dynamical principles to be later pointed out. Primarily it will be admitted that any substance, gas, liquid or solid, upon which work is done, acquires heat in proportion to the energy expended upon it, which heat, if prevented from escaping, at once results in an increase of temperature of the substance. If the mechanical energy so converted be of known amount, we may calculate from the mass and specific heat of the substance or body upon which such energy is expended the rise in temperature. Even if air at ordinary temperature under high pressure escapes through a tortuous or frictional passage surrounded by a good heat non-conductor, it emerges hot. The higher the pressure and the greater the friction met in the passage the greater the increase. The heating is directly related to the work done upon the mass.

If a liquid be substituted for the air the general result is the same, and the liquid may be made to boil upon its escape. If a somewhat plastic solid like hard pitch be subjected to the process, the energy required will be greatly increased, or the pressure required to force it through the tortuous passage of some length will be great. It may emerge hot and melted if the conditions be properly selected.

If now it be assumed that any solid be subjected to a pressure such as to cause it to flow in a tortuous or restricted channel, it will, in so moving, rise in temperature, and continue so to rise until it has reached a degree of fluidity such as to lessen or practically stop the absorption of energy in moving the mass; or until it escapes from the passage through which it is being impelled. The pressure is but one factor of the energy, the other being the distance through which the pressure acts. The pressure required depends upon the resistance to motion, which in turn is greater with more rigid bodies and

greater with increase of distance through which friction is met and overcome. The pressure or force required will be at a maximum when the solid mass starts cold or nearly so and will diminish as the temperature is raised and consequent plasticity or fluidity brought about. A rock mass forced to move under great pressure over distances of thousands of feet must soon become melted in the process. It is not necessary to assume that the mass so heated starts cold. It may start at any temperature at which it possesses sufficient rigidity or viscosity to require the exertion of great force to move it in the assumed restricted or tortuous passage or channel. Great velocity of movement in such passage means of course great energy expenditure and rapid heating. The idea thus outlined may now be applied as an explanation of volcanic phenomena. For example, a hot-water spring may be the result of the water having been forced by high pressure to traverse somewhat porous rock, or to pass through narrow but long fissures in which it is churned for a long time before escaping. In like manner any rock mass which, subjected to very high pressure, begins to flow, must become heated. If its distance of traverse be great enough in a restricted fissure or channel, it must melt, or even become so heated as to partially vaporize when the pressure is relieved, as when it finally escapes. Let it be admitted that the flexures taking place in the earth's crust or in the outer portions of its mass may bring to bear upon deep-seated and perhaps already heated solid rock masses a sufficient pressure to cause them to readjust their positions, and the condition demanded by the theory is present. Such a condition would mean movement of such masses over considerable distances at high pressures, with the final result of the formation of molten streams ready to escape upward from the pressure exerted upon them. A vent would at last form and the rush of the partially melted rocks towards and out of this vent would become a lava flow. These actions would naturally occur at places of flexure such as would tend to form a ridge, and the loading and sinking of sea bottoms as a consequence of sedimentary deposits would be favorable, as is well known, to such flexure as would tend to heavily compress the rocks along the line of flexure deep down from the earth's surface, while relieving or not increasing pressure near the surface. The compressed rock would in general tend to be shifted or made to flow outward at the line of flexure. This view accords well with the facts. Volcanoes exist along lines more or less parallel to or adjacent to sea coasts or along the weak lines in the earth's surface. It will easily be seen that a single volcanic vent or pipe may serve to relieve or provide a point for outflow for the shifting of material over a great length of flexure deep down under the earth's surface. As the flow and fusion would be a somewhat gradual process, it may well be that only when the vent is about to open will there be earthquakes and great subterranean noises, more or less local to the place of outbreak. Very probably eruptions in which melted lava does not appear to have a part, but in which steam and gases, sand or mud are ejected, are nevertheless dependent upon an upthrust of lava or a subterranean lava stream, which never reaches the surface, but the temperature of which is such that, on its reaching hydrous rock strata, the water is evolved as steam at high pressure, which, entering superincumbent layers, gives rise to mud eruptions, or escapes from vents or fumaroles.

It would be expected that such rock masses as, under pressure, would yield most readily would be the ones to flow and form lavas. They would also be likely to be the more readily fusible masses, assuming that before the process of compression and extrusion begins they exist at a temperature more or less elevated above that at the surface of the earth.

Special Correspondence.

London.

Annual Report of the Mt. Morgan. — The Great Gold Mine Now Produces Copper.

This is in many respects the greatest gold mine ever worked by man, for its output has been \$59,341,000, from which dividends have been distributed to the amount of \$32,646,358. The mine began to be productive in 1886, and it promises to be a source of great wealth for many years to come. During the past fiscal year the production was 121,606 oz. of gold, equivalent to about \$2,432,000. Under the hill of gossan constituting the immense outcrop of the deposit, there has been found sulphide ore rich in copper, and in their last report, this new feature of the enterprise is emphasized.

The directors state that the chief feature of the past year has been in connection with the erection of the copper reduction works and the necessary equipment of the mine for extracting the auriferous copper ore. The works, which consist of three blast-furnaces and two converters, are capable of treating 10,000 tons of ore per month, and provision has been made for additions which are now under consideration. The first blast-furnace was blown in on January 20, and the converter commenced operations on April 18. Progress was at first slow, but the whole plant has given complete satisfaction. The production of bessemerized copper to June 30 amounted to 484 tons, of which quantity 302 tons were produced in the last month, the whole containing approximately 7,085 oz. gold. The blister copper produced averaged 98.6% pure copper, and contained at the rate of 14½ oz. gold per ton. A contract for the purchase of the first year's output was entered into with the Delmar Copper Refining Co., of New Jersey. The question of erecting an electrolytic refinery has not been settled finally, but will receive attention early enough to have everything complete during the term of the contract, if found advisable. The copper-producing operations have not extended for sufficiently long periods to determine the cost of mining, smelting, and realization, but sufficient is known to show that the estimate made when the equipment was decided upon (35s. per ton of ore) allows an ample margin.

The reserves of the auriferous copper ore were referred to in detail last year. Since then no prospecting has been done, but openings made for extracting it have shown that the quantities are somewhat greater. These estimates showed that 1,212,000 tons, containing approximately 3½% copper and 8 dwt. gold; 1,597,000 tons, containing approximately 3% copper and 2½ dwt. gold; and large unestimated quantities, containing from 2 to 3% copper, and from 1 to 2 dwt. gold. However, sufficient is known of this latter low-grade ore to show that it is very extensive, exceeding in amount the aggregate of high and medium grades. The prospect of turning this low-grade ore to profitable account has been considered so great that the equipment of the mine has been determined largely with a view to that object. In the works, as built, space was left for two more furnaces, in addition to the three already in position, and provision was also made for extending the converter plant. This means of increasing the output will have early attention.

Turning to the mine as a gold producer, it is seen that the output was 114,521 oz. of fine gold from 280,718 tons ore. The average assay-value of the ore was 9.16 dwt., as compared with 9.71 dwt. for the previous year. The amount of oxidized ore extracted from the open-cut workings was 135,210 tons, which yielded 52,882 oz. gold. The average yield per ton was 7.82 dwt., com-

pared with 8.41 dwt. for the previous year, which shows a decrease in the grade of 0.59 dwt. The amount of sulphide gold ore treated was 108,736 tons, which yielded 58,866 oz. gold, averaging 10.82 dwt. fine gold, which is about 5% lower than the previous year.

An important consideration in connection with the immediate future of the mine is the limited quantity of better grade oxidized ore now available. "Most of this ore," the directors say, "having been treated, a further reduction in the yield from the oxidized ore may be looked for." The grade of oxidized ore during the past year was materially assisted by the ore uncovered by the steam shovels in the removal of the overburden on the east side of the mountain. The better grade ore thus provided is, however, becoming exhausted, and although the removal of the overburden continues to disclose fresh bodies of ore, the latter discoveries have been low in grade or containing too large a percentage of pyrites to permit of treatment at the oxidized ore reduction works. The main supply of the oxidized ore was obtained from the western side of the mountain, where the ore continues low in grade, the average for the year only slightly exceeding 5 dwt. gold per ton.

The accounts for the 12 months show that the period opened with £18,771 in hand, and closed with a balance of £4,922, after the payment of £150,000 in dividends. The total disbursements for the year were £654,758, no less than £266,419 having been paid in wages.

Calumet, Michigan.

The Michigan's New Mill. — Winona to Start Milling. — Shaft-Sinking on the Wyandot. — The Seneca Property and Its Chances. — Diamond-Drilling at the Isle Royale and Rhode Island.

Shipments of ore from the Michigan mine to the mill of the Mass Con. Mining Co. on Keweenaw bay were discontinued this week, the Michigan's lease of one stamp having expired. The ore is now being shipped to the Atlantic mill, being transferred to the Copper Range railroad by the Mineral Range road. The Michigan has leased two heads in the Atlantic stamp-mill, which will be sufficient for its needs until its new mill is completed. There will be no increase in the production for some time. Work on the new mill, adjoining the Mass mill on Keweenaw bay, will not be completed for a year, as it will be necessary to wait several months for machinery and building material. Work on the foundation is now under way. The plant will consist of two stamps, and it is estimated that the cost will reach \$180,000, which the Michigan company will undoubtedly be able to pay from current earnings without making an assessment. The ore is yielding better than 20 lb. copper per ton stamped, which is higher than the average secured by some of the dividend-paying mines of the Lake Superior district. The new C shaft is opening promising ground and will become an important factor as soon as it is provided with a rock-house and railroad facilities. These will be furnished without any further delay.

It is current gossip that the Adventure mill at Edgemere will treat the ore from the Winona mine, which will begin production within the next six weeks, or as soon as the new rock-house at No. 3 shaft is completed. There is much activity at the Winona property. The sinking of the new No. 4 shaft is being pushed as rapidly as the conditions permit, and as opening work is progressing from two points underground, simultaneously with sinking from surface, it is expected that the shaft will be opened to the third level in short order. Repairs to the foundation of the 15,000,000-gal. pumping engine at the Adventure's stamp-mill have started. Auxiliary pumps will be installed to furnish the water necessary

for use in the stamping and concentrating departments in the meantime.

The Wyandot shaft has reached a depth of 850 ft. and work is progressing continuously. It is purposed to put the shaft down to a depth of 1,000 ft. before lateral explorations are started. The shaft is in the foot-wall, about 75 ft. from what is believed to be the Winona amygdaloid lode, which has not been exposed below the fourth level. It is expected that the lode will be reached within a short time. As soon as the cross-cut reaches it, drifts will be started.

On September 20, the Calumet & Arizona Mining Co., with main offices in Calumet, will pay a quarterly dividend amounting to \$700,000. The North Butte will disburse \$800,000 on September 29 as a quarterly dividend, and the Wolverine's semi-annual dividend, payable September 31, will aggregate \$540,000. The Copper Range pays its seventh quarterly dividend, amounting to \$576,202, on October 1. These enlarged distributions of earnings among the shareholders of the various corporations, reflect better than anything else the extremely prosperous condition of the larger copper producing companies at the present time.

Occasional reports are circulated to the effect that the Seneca property, adjoining the Mohawk and Ahmeek, is to start operations, but it is not likely that any activity will result at that mine this year. The Ahmeek and Mohawk are doing well, and in a measure they are proving up the Seneca's prospects. The Calumet & Hecla Mining Co. has started a couple of shafts on its property lying immediately northeast of the Mohawk, with favorable results. The Seneca bears the same relation to the Calumet & Hecla's property, known as the Gratiot, that the Allouez does to the Ahmeek, the former in each instance being the 'deep level' of the latter. The Seneca is one of the most promising undeveloped properties in the Lake Superior copper district and undoubtedly will make a good-sized mine in time, but it appears to be the present policy of the company to permit the adjoining properties to develop their lands and thus prove the Seneca portion of the Kearsarge amygdaloid bed.

In addition to the two shafts the Calumet & Hecla Co. is sinking on its Gratiot property, it has four other shafts under way in Keweenaw county. These are situated on its Delaware mine, where diamond-drill exploratory work also is under way. Three of the shafts are on the Montreal river amygdaloid, and are known as No. 1, 2, and 3. The other shaft is on the Calumet conglomerate and is known as No. 6. No. 1 shaft, the first one started, offers the best showing. It is over 100 ft. deep, with drifts at the 100-ft. level, and the showing is understood to be above the average.

Sinking is progressing in the exploratory shaft which the Isle Royale Co. is putting down upon the Baltic amygdaloid lode. The shaft is about one mile north of the Superior's boundary line. At the Isle Royale's shaft on Section 11 the showing continues encouraging. This shaft, known as No. 6, will be prepared to furnish a larger production shortly. Diamond-drill work, to determine the best site available for a shaft south of No. 6, has progressed slowly, owing to the large number of boulders in the overburden.

At the Rhode Island, diamond-drilling was discontinued a short time ago. One drill had been in commission for ten months at various points on the surface, finding the Kearsarge amygdaloid and determining its depth. Since the drill on the surface went out of commission, two have been in use underground. These drills are placed on the 1,200-ft. level of No. 2 shaft. They are being operated to disclose the West, Allouez, and Pewabic lodes at that depth.

It is expected that the cross-cut which the Franklin

Co. is driving from the older workings at the Franklin Junior mine, to intercept the Kearsarge amygdaloid, will reach that formation within a few days.

Joplin, Missouri.

Prosperity of the Lead and Zinc Mines.—Activity at Webb City.—New Enterprises and More Concentrating Mills.

The highest price reported for zinc ore last week was \$48 per ton. The assay basis was \$42 to \$44, with a few bins selling at \$45 per ton for 60% zinc. Lead ore continues strong in demand and price, and \$82.50 was reported paid for one bin in Webb City. From \$80 to \$81.50 was paid in Joplin. The zinc ore shipment for the week was 69 tons larger and the lead ore shipment for the week 59 less, with a decrease in value of \$6,954, compared with the previous week. The shipment of zinc ore this year is 17,500 tons larger than the same period of last year, and the lead ore shipment is 5,000 tons larger and the value \$1,303,994 greater. The shipments for last week were: Zinc ore, 5,419 tons valued at \$238,318; lead ore, 710 tons valued at \$56,583; combined value, \$294,901.—The Grace Zinc Co., owner of a 20-acre lease on the Granby Mining & Smelting Co.'s land, at Chitwood, has completed a drill-hole to a depth of 161 ft., where a 25-ft. body of pay-ore was encountered. The drill has been moved and work on the second hole commenced.

The La Grande Mining Co., operating a lease on land of the Granby Mining & Smelting Co., has started its mill again this week and expects to be able to run steadily hereafter. The mine has been shut down for some time pending deepening of the shaft and further development work.—The Continental Zinc Co. turned in last week 141 tons of zinc ore and nine tons of lead ore, thereby heading the list of Joplin producers. This property is situated immediately west of the city and is an old and steady producer.—The Paxton mine, on the Missouri Lead & Zinc Co.'s land, owned by Conklin & Ritter, in which a rich run of zinc ore was found a few weeks ago, last week turned in 47 tons of zinc ore. Since striking the ore, and in cutting a drift, one of the richest bodies of ore ever found on the Missouri Lead & Zinc Co.'s land has been developed.

The concentrating mill of the Florence Mining Co., operating on the Guinn land, north of Webb City, which has been in litigation for some time, was purchased last week at private sale by F. C. Wallower, of Joplin, for the Disbrow Mining Co., composed of Joplin and Webb City parties. The mill will be moved to the Bradford-Kansas City Mining Co.'s lease, on which the Disbrow will operate.—H. F. Chapman, a capitalist from New York, has formed an organization to be known as the Royalty Land & Mining Co. The stock will be held by himself and a number of Eastern friends. The company recently purchased 20 acres of the Teel land, near Duenweg, and in close proximity to the famous Log Cabin and McAbey & Reno lead mines. The company will maintain an office in Webb City.—The Lelah Mining Co., composed of Ben Peppers, Cob Pugh, Roberson brothers, and others, of Webb City, operating on the Moss 40-acre tract north of Alba, which was recently purchased by T. F. Coyne, of Webb City, for \$80,000, turned in last week 73 tons of zinc ore.

The Moss Mining Co., represented by the Hardy brothers and others of Webb City, and operating on the same property, (each company having 20 acres), turned in 44 tons of zinc ore. Each of these companies has just completed concentrating mills and is getting in shape to run regularly, and apparently have as good a property as there is in that part of the district.

Butte, Montana.

Production of Copper in August. — Strike in the Ophir. — Another Company Organized. — The Ida-Montana to Resume Operations. The Niagara Lessees Doing Well. — A Discovery in the Corra.

The Butte district produced in August 34,057,034 lb. of copper, the increase over the July production being but 135,660 lb. The different companies contributed to the August production as follows:

Company.	Tons of ore.	Pounds of copper.
Boston & Montana.....	116,250	8,835,000
Anaconda.....	126,480	9,106,560
Butte & Boston.....	18,600	1,320,600
Washoe.....	17,205	1,238,760
Parrot.....	11,501	689,670
Trenton.....	16,926	1,167,894
North Butte.....	32,581	4,329,150
Red Metal.....	42,625	3,026,375
Original.....	30,225	2,206,425
East Butte.....	6,510	637,980
Pittsburgh & Montana.....	4,960	357,120
Miscellaneous.....	15,500	1,131,500
Total.....	439,363	34,057,034

The daily output of ore and the average yield per ton in copper were as follows:

Company.	Tons.	Pounds.
Boston & Montana.....	3,750	76
Anaconda.....	4,080	72
Butte & Boston.....	600	71
Washoe.....	555	72
Parrot.....	370	61
Trenton.....	546	69
North Butte.....	1,050	133
Red Metal.....	1,375	71
Original.....	975	73
East Butte.....	210	98
Pittsburgh & Montana.....	160	72
Miscellaneous.....	500	73
Total daily output.....	14,171	
Total daily copper production, 1,098,614 pounds.		

The recently organized Butte Central & Boston Copper Corporation owns the Ophir mine, in the southern part of the Butte district, in which lessees a few days ago made an important strike on the 300-ft. level, about 230 ft. east of the shaft. Average assays show 300 oz. silver per ton and 5 to 6 % copper. The vein is believed to be one of those being opened in mines some distance east of the Ophir. The extent of the orebody has not yet been determined, the opening into it having penetrated but eight feet.

The latest company organized in Butte is the Butte Extension Copper Co., incorporated under the laws of Massachusetts. It has acquired four mining claims in the southeastern part of the Butte district, known as the Exemption, Canyon, Mountain Spur, and Colleen Bawn. Very little development work has been done on the claims, but they are regarded as good locations. There is a shaft sunk 150 ft., many years ago, on the Exemption, and a vein of copper ore about 10 ft. wide was cut. It is stated that all the ground has been bought and paid for.

The Eagle Mining Co. will sink its shaft 200 ft. deeper, and run drifts east and west at a depth of 400 ft. The Ida-Montana Mining Co., composed principally of Michigan and Wisconsin capitalists, is about to resume operations on its properties in the foothills east of Butte. The first shipment of machinery, ordered some time ago, has arrived on the ground. It consists of a new hoisting engine capable of working to a depth of 1,500 ft., boilers to furnish 250 h.p., and a 16-drill air-compressor. A pump is also included capable of lifting 500 gal. of water per minute to a height of 1,000 ft. The property consists of two full claims, on which two shafts have been sunk on the vein, each about 115 ft. deep. It is the intention of the company to sink a three-compartment shaft to a depth of 1,000 ft. The lessees who are working the Niagara mine, recently purchased by the Butte & Superior

Co., are still in possession of the property and are regularly shipping ore. The Niagara is a silver-gold producer, and is one of the oldest mines in the district, though it has never been opened below 300 ft. It is the opinion of many mining men that the Niagara, like all other mines, in the Butte district, will turn into copper with greater depth, and the Butte & Superior Co. will open it through the Blackrock shaft at a depth of 1,000 ft. or more.

The shaft of the Bullwhacker mine has reached a depth of 380 ft. A station will be cut at 400 ft., and cross-cut to the vein recently struck by the lessees about 100 ft. south of the main shaft.—The Red Metal Co. has opened on the 1,600-ft. level of the Corra mine the vein which the old company lost on the 1,400, where the vein was faulted.

Salt Lake, Utah.

Share Business for the Week.—Dividends From Tintic.—Freight Rates Considered Excessive.—News From Park City.—More Sampling Works.—The Nevada Douglas Copper Co.

The ore and bullion settlements last week in Salt Lake amounted to \$612,200, making it the best week of the year. During the same period, on the Salt Lake Stock & Mining Exchange, there were sold 259,184 shares of stock for \$110,868. The directors of the Lower Mammoth Mining Co., operating near Eureka, in the Tintic district, have decided to call a stockholders' meeting to discuss the matter of increasing the capital stock. Money is wanted to sink the main working shaft from the 1,200 to 1,700 ft. or deeper, making heavier machinery necessary. This creating and selling of treasury stock, rather than continuing to levy assessments, is considered to be the most satisfactory means of raising funds to provide for the proposed improvements.

Two Tintic mining companies have posted dividends this week. The Bullion-Beck & Champion pays 10 cents per share, or \$10,000; the Uncle Sam Consolidated, one cent per share, or \$5,000. The Daly-West, of Park City, has also posted its usual quarterly dividend of \$108,000.—A settlement of the question of freight rates on ore shipped from the Tintic mining district to Salt Lake valley smelters is still pending. Producers, as stated recently, have been making a united effort to induce transportation companies to grant them a lower schedule on certain classes of ore. They submitted a long list of figures showing the output of the district in the past and others showing what it might be were certain concessions granted, which would permit profitable shipment of ore assaying about \$10 per ton. There are many thousands of tons of ore of this class available in Tintic mines which cannot be handled to advantage at the present time. Producers asked for a rate of \$1 per ton on all ore of the value of \$10 per ton or under—a reduction of 50 cents per ton—which the railroads refused. They were then asked for a rate of \$1.25 per ton on ore assaying \$15 per ton or under, with present rates to remain in force on everything going above \$15. A decision from the railroads is expected this week.

Shipping ore has been found on the 800-ft. level of the Little Chief mine in Tintic district. Development work is to be resumed at the Naildriver mine, at Park City. The directors of that company have levied an assessment of three cents per share, to collect \$9,000 for this purpose.—The development of a new orebody on the 1,200-ft. level of the Daly mine, at Park City, has created much local interest. Its extent, however, is yet to be determined.—Interesting developments have been taking place at the Treasure Hill mine, in the Snake creek district, near Park City. The property is about to make its initial shipment of ore.—The Ontario Silver Mining Co. is making a little more than expenses from

ore shipments, which are the product of the upper levels of the mine. Work is still progressing with the re-opening of the drainage adit.—The management of the Little Bell mine, at Park City, reports having marketed about 1,000 tons of ore in August.

Chicago parties have secured a bond and lease on the Copper Coin property in Morgan county.—Bert L. Smith of Tonopah, with others, has secured a bond on the Mountain Chief mine in Bingham, which is to undergo development.—Herman Barnett of Salt Lake, manager of the Cedar Mining Co., operating near Milford, Beaver county, reports having found a good body of silver-lead ore of shipping grade on the 225-ft. level of that property.

The Taylor & Brunton and Pioneer Sampling Companies, operating near Salt Lake, are preparing to provide additional equipment. The former will increase its capacity about 50%, 45,000 tons monthly.—Much interest is being taken in Salt Lake over recent developments in the Yerington, Nevada, copper district where a number of Utah people have secured property. The articles of incorporation of the Nevada Douglas Copper Co. were filed last week and the management has started vigorous exploration. J. D. Wood, president of the company, is now on the ground to be present at the starting of the main adit. It is learned that the company will probably close a contract to purchase power from a plant situated on the Truckee river. In this event transmission wires will be strung promptly, insuring electric energy at the Douglas camp within 60 days. If this arrangement is concluded the Douglas Co. will be relieved of the necessity of making an investment in a plant of its own, although it has acquired good water rights and power sites. Should the pending power deal fall through, the original plans will be adopted.

Denver, Colorado.

Leadville Still Makes a Big Output.—A Strike in the Little Johnny.

New Work at Silver Plume.—Sale of the Muscovite.—More Mills at Georgetown.—The Newhouse Tunnel.—News From the Dumont and Montezuma Districts.—Zinc From Breckenridge.

Leadville is producing 90,000 tons of ore per month, a greater tonnage than it ever produced in the past. This seems remarkable when one considers that Leadville began to produce in 1859. The Yak Tunnel company has taken over the control of the Fortune mine. This property is near the Resurrection and will be conveniently worked through the Yak adit. The Half-Moon Mining & Milling Co., also near Leadville, has this summer completed a good wagon-road to its property and installed a small plant of machinery. The manager is now getting out plans for a mill.—Some lessees on the Little Johnny have struck a rich pocket. H. Hawkins, one of the lessees, brought into town a 15-lb. piece that might fairly be called a gold nugget. The Ibex company, which owns the Little Johnny, has prospered under the leasing system and at the same time some of the lessees have also done very well indeed.

Two enterprises are starting on Long & Derry hill. Harry Mamlock, manager of the Doris mine, has opened a fine body of lead carbonate and is shipping actively. P. W. Breene has taken a lease on the Long & Derry mine. Mr. Breene will be recalled as the energetic promoter whose name was associated with many of Leadville's earlier enterprises. At present he is giving most of his attention to re-opening the old Col. Sellers mine. He is preparing to build a large concentrating plant for that property.

At Silver Plume, one of the mines that is attracting local attention, is the Smuggler group on Brown & Sher-

man mountain. Dr. Burt, manager for the Main Gulch Mining Co., has been developing this property and has opened up some extensive bodies of good ore. Assays as high as \$225 per ton have been received. Some of the ore carries a heavy percentage of zinc; this ore is sent to the Terrible mill, where the zinc and lead are readily separated.—The old Lebanon tunnel, which has been idle for 20 years, is now shipping.

The Muscovite mine on Democrat mountain, near Georgetown, is reported to be sold to Denver investors for \$50,000. This property was at one time a heavy lead producer and has of late been re-opened. In the early days, however, less attention was paid to securing surface rights than is necessary nowadays and difficulties arose over dumping room. The new owners plan to obviate this difficulty by going farther down the hill and driving a cross-cut tunnel. It is said that there is ore enough developed to justify a mill as soon as the new adit-cut reaches the vein.

The old mill near the portal of the Mineral Chief is being overhauled at present and will be run by the Linn Consolidated Mining Co., but it will not be large enough to handle the tonnage of the mine and additional machinery with 30 tons daily capacity will be provided at once. W. D. Hoover, the principal owner of the Griffith mine, has begun grading for a 50-ton concentrator. Work on the 50-ton concentrating plant for the Ramsdell Mining & Milling Co., is to be started September 10.

It is not possible to give all the news about each camp during these busy summer months. Upper Clear Creek is especially prolific in new enterprises. Ever since the Argentine Central Railroad was started this part of the State has been extremely active. They are paying men \$3 and board in East Argentine now, and it is almost impossible to get men even at that attractive wage. Down at Idaho Springs matters are equally flourishing, but there are not as many new ventures. The developments from the long adits are the principal feature of the summer's work. The Pine Shade, the Gem, and the Saratoga all report fine discoveries in laterals from the Newhouse tunnel. The Gem in particular deserves mention, for they have the highest grade ore seen in the mine for many years. It was discovered in a winze sunk below the tunnel-level. At Dumont an engineer named Bohn has been running some cyanide tests for S. K. Behrend, of the Cass County Prospecting Co. The tests are just as successful as numbers of others have been in this district, when conducted by competent men, and it is probable that this company, as well as others, will add a cyanide annex to their mill in the near future.

George C. Weber, president of the Great Northern Mines Claims Co., operating on Mill creek, above Dumont, is planning a hydro-pneumatic plant of 50-h.p. capacity, to drive another long adit. Joel F. Vaile, the distinguished attorney of Denver, has done something in that line on Mill creek, and succeeded in demonstrating some interesting geological theorems which have been useful to him in his law practice. We will hope that Mr. Weber will get something else besides geological data.

The Montezuma district, in Summit county, seems to be sharing in the almost unprecedented activity which besets the mining parts of Colorado this year. Montezuma is not unknown; it may more properly be spoken of as forgotten, until this year; now the hills are alive with men and teams, and the regular boom of the shots at the close of each shift sounds like the bells of a Western Union clock. Ernest Le Neve Foster, the well-known mining engineer, has shown his faith in the district by putting 12 men to work on the Waterloo.

Breckenridge has come to the front this summer with unexpected production of zinc. It seems strange for a

camp noted chiefly for its gold-placer operations to leap to the front with a big zinc production. In reality, however, it is not a sudden change. The zinc ore was known and cursed in the old days when the smelters levied a penalty for it and since the modern methods of treating and separating zinc ore have come in vogue, Breckenridge has been getting ready to ship its zinc. It takes a little while, however, to negotiate sales or leases, and to unwater old mines, and even then the best promoters are apt to take up the poorest mines, so it has come about that Breckenridge has only just begun to turn out a considerable tonnage of zinc. The Country Boy claim, belonging to Wm. Lennox, of Colorado Springs, and under lease to the Lanyon Zinc Co., produces about 600 tons per month of the highest grade zinc ore ever received at that company's works from a Colorado mine.

The Moffat road has at last seriously taken up the matter of building the tunnel through the main range, without which this railroad can never be a serious factor in the transcontinental business. The directors are seriously considering the plan of boring a six-mile tunnel, instead of one two miles long. If they decide on the six-mile tunnel it is said the Moffat road will have the best transcontinental grade of them all, not excepting the Union Pacific, which crosses the range where nature made it low and flat.

New York.

Annual Report of the Smelter Trust.—Wall St. Is Disappointed.—
Big Operations.—New Plants in Course of Construction.

The annual report of the American Smelting & Refining Co., for the year ended April 30, was rather a disappointment to operators on Wall street. In consequence of the statement, shares were weak and there would have been a bigger drop if the poor showing had not been already largely discounted in a recent decline of both preferred and common stock. As it was, the strong interests behind this enterprise came to the support of the market and it recovered.

According to the statement made, the gross earnings were \$11,665,885, an increase of \$1,159,202 over the previous year; net earnings, \$10,161,358, an increase of \$1,262,546; balance available for common dividends, \$5,274,054, an increase of \$1,155,142. For some weeks there have been hints to the effect that the common stock of the company was to be put on a 10% basis, but as these did not come from the management the latter cannot be held responsible for them. The common aggregates \$50,000,000, and now it pays 7% annually, having been put on that basis in October last. Should 10% be paid, it would nearly wipe out the item put to the account of balance after the preferred dividends had been met. However, the statement given out yesterday refers to the condition of the affairs of the corporation over four months ago. Since the beginning of the new fiscal year business has improved and the company has been making more money than ever. In the financial district the opinion was expressed that the 10% dividend on the common stock was still within the probabilities of the near future. Daniel Guggenheim, the president of the company, says in his statement to the stockholders:

In addition to new construction and improvements of a miscellaneous nature made at the various plants during the past year, the following notable additions have been made: Perth Amboy, N. J.; a new copper-refining plant, with a capacity of 75,000,000 lb. annually; Omaha, Neb., new copper-converting plant; Leadville, Colo., increased capacity of lead smelter, equal to 7,500 tons of charge per month; Colorado and Perth Amboy, additional land, giving increased facilities. The valuation

of the securities of the company also remains unchanged, while the increase in the investment account represents the value of the company's additional holdings in various subsidiary companies. Although it had been thought the earnings of the American Smelters Securities Co. would not equal its fixed charges during the first year of its existence, for the reason that many of its large properties were still in the development and construction stage, yet the earnings of the Smelters company have exceeded its fixed charges by \$500,000; consequently no demand has been made on account of the guarantee by the American Smelters Co. on the series B preferred stock of the American Smelters Securities Co.

The prosperity of the American Smelters Securities Co. is of so great moment to the stockholders of this company that it will doubtless be of interest to note the following, regarding its various properties. In addition to the mining interests of that company, which are operated largely as a base of supply for its various smelting works it had in successful operation at the time of its organization lead smelting and refining works at San Francisco, Everett, Wash., Federal, Ill., and Tacoma, Wash., and also copper smelting and refining works at the latter place.

The Federal company's plant is to be doubled. Additions are to be made to the works at Velardena, Mex., lead and copper smelters are to be built at the latter place, and copper smelters at San Francisco and Garfield. Some of these are nearly completed.

Cripple Creek, Colorado.

New Strike in the Lonaconing.—Good Output From the Gold Sovereign.
—The Joe Dandy in a Tangle.—The Victor Still Productive.—
Hammer Drills Becoming Popular.—The Drainage Adit.

Carlton & Newcomb, operating a lease on the Lonaconing mine, on Beacon hill, are shipping three cars of fair grade ore per week. This ore is being obtained from a new strike made a few weeks ago at a depth of 280 ft. The lessees, who have been working on this property since the beginning of the year, decided a short time ago to clean up and surrender their lease owing to the lack of pay-ore, but this new strike was disclosed in time to keep the mine in operation. On the Lonaconing dump, Walkes & Bradford, sub-leasing from the above parties, are shipping ore of good grade, a consignment going out last week.—The output of the Mary McKinney mine is around \$48,000 for the month of August, the mine having done exceptionally well. During the month forty cars were shipped, having an average grade of \$40 per ton.

Owing to the breaking of the crusher of the Ironclad cyanide mill, operations have been temporarily suspended. Another crusher, purchased from the Eagle Ore Co., is being installed, it is of greater capacity than the old one, being able to put through 100 tons of rock in ten hours. Low-grade ore is being shipped to this mill from the War Eagles mine on Bull hill, this being the third consignment of 100 tons to go to that mill. Atherton, Braden & Hill, leasing on the Specimen claim of the Stratton Estate, on Bull hill, are cross-cutting from the bottom of the shaft, which is 150 ft. deep, to cut the big Specimen vein, which has produced so much good ore for the Western Investment Co. and from which this company shipped four cars of ore per week for several months. A distance of 50 ft. is calculated to be sufficient to drive the cross-cut to cut this vein.—The Findley mine has started to ship ore to the new mill erected by the Golden Cycle Co. at Colorado City. The mine has been storing the ore broken for several months, and it is expected that about 100 tons per day will now be shipped

to the mill.—The August production of the Gold Sovereign mine, on the west slope of Bull hill, was approximately 1,100 tons of ore, averaging $1\frac{1}{2}$ oz. gold per ton. This mine ranks among the principal producers of the district. The greater part of the tonnage is contributed by the company and the Harry Diltz lease. A new engine was installed this week, necessitating the suspension of hoisting for a short time.

Work has been suspended on the Joe Dandy property, on Raven hill, pending the disentanglement of the company's financial affairs. The manager, J. M. Wright, has gone to Chicago for this purpose. It is rumored that a mill will be erected on this property in the near future for the treatment of the low-grade ore of the mine.—Pete Hansen, operating a lease on a portion of the Garfield-Grouse claims of the Stratton Estate, on Bull hill, has struck some good ore; a stringer found near the surface was followed down, developing into an orebody at a depth of 200 ft. The Western Investment Co. is shipping large quantities of ore from the Specimen and Sacramento claims, on Bull hill; the latter claim has been equipped with a new and larger ore-house to facilitate handling the ore from the big Specimen vein. The two claims between them produce a car of ore per day.—The surface equipment of the Forest Queen mine, on Ironclad hill, is being thoroughly overhauled. New coal bins have been put in and the self-dumper has been put in working order. The shaft is free from water and the property ready for production immediately. This mine is under lease to Chicago parties, Oscar Fogelman looking after their interests.

Very little is now heard of the old famous Victor mine on the eastern slope of Bull hill, but this mine still continues to produce on a small scale through the efforts of lessees. Fred Strong, a nephew of D. H. Moffat, has the entire property under lease. This mine was one of the first in the district to be discovered and was formerly one of the best producers in the camp. A good vein has recently been opened up at a depth of 60 ft. on the Vindicator No. 6 property by Hamor & Co., lessees.

There are no less than four varieties of 'buzzer' drills being sold in this camp at the present time; they are becoming more and more in evidence as time goes by. Stratton's Independence has replaced the $2\frac{1}{4}$ in. drills, in use for several years, by 40 of the hammer or 'buzzer' drills of the Hardsocg variety. It is said, on good authority, that not less than 1,000 more miners will be working in six months than there are now as a result of the invasion of the little drills. Many veins and stopes impossible of operation with the ponderous old-style drills will be worked easily by the use of buzzer, and the small lessee will have twice the show that he now has, either by use of the costly big fellow, or the hand steel.

At a meeting of the directors of the Cripple Creek Drainage & Tunnel Co. on August 30, officers were elected for the ensuing year, contracts between the tunnel company and mine owners were read and formally approved, and executive committee chosen to finance the scheme and supervise the work of construction.

The contract, after reviewing the duties of the tunnel company, in constructing a bore from Gatch Park to the Vindicator shaft, which will cut the mines of the district at an average depth of 2,000 ft., provides for subscriptions to the fund by mine operators. Subscriptions will be made by the purchase of tunnel company's stock at the par value of \$1 per share. There are one million shares in the treasury and a minimum of \$700,000 must be pledged by November 15 of this year or the contracts are invalidated. The committee will endeavor to secure \$800,000 or \$850,000 if possible, so as to secure an adequate working fund. As previously stated, nearly \$600,000 is assured and the remainder of the money is in sight.

Toronto, Canada.

Gold Discovery in Alberta.—The Silver Nugget of the Nipissing. A Discovery Near Peterborough.—Activity in the Manitou District.—A Find of Silver Ore at Port Arthur.

An important discovery of gold is reported in the Peace River country, Alberta, by the Macdonnell survey party employed in Government work in that region, who have arrived at Edmonton, Alberta, bringing with them many rich samples. The discoveries were made 37 miles below Fort St. John and 17 miles from the British Columbia boundary. The ore is a shale through which are scattered small specks of gold. On the application of crude tests it showed from \$7 to \$32 per ton, but it is believed that a proper assay will yield even better results. The gold-bearing rock is a bed of shale projecting out of the river bank, and the topographical formation of the country indicates that it is thousands of acres in extent. Seventeen claims have been located along the river bank.

Hydraulic operations at the Nipissing mine, Cobalt, have resulted in the finding of an enormous nugget, said to weigh between 3,000 and 4,000 lb. and to be of almost pure silver—the value being estimated at \$25,000. The stock of the company is very active at present and its publicity department well organized.

Mr. Hanson, manager of the West End, Silver Mountain, Badger and Porcupine silver mines in the Port Arthur, Ontario, district, recently acquired by a syndicate of New York and Ohio capitalists, is at Port Arthur engaging a large force of men to work the mines.—Silver has been discovered by an American prospector on the farm owned by a man named McKniff, about six miles north of Peterborough, Ontario. A sample is reported to have given good returns.

H. W. Scattergood, of Philadelphia, president of the Summit Lake Gold Mining Co., and A. Campbell and A. MacLaren, of Detroit, vice-president and secretary, respectively, have returned from a two weeks' visit to the property comprising 500 acres in the Manitou district of northwestern Ontario. At the company's Little Master mine drifts are being pushed into the orebody, the output—in addition to gold—including a good percentage of galena. The company has appointed Dryden Smith, lately manager of the Laurentian, as general superintendent of the Little Master. The Volcanic Reef mine, adjoining the Little Master, is now under new management, the president of the company being J. V. H. Cook, of Cannonbury, Pa. Richard Jennings, a California mining expert, is making an examination of the property previous to re-commencing operations. The Minnehaha gold mine, owned by the Minnehaha Mining & Smelting Co., of Buffalo, was recently visited by Senator Louis Fechter, president, and other officials, who noted improved conditions as a lower level was reached. The quality of the ore at 75 ft. had improved. The quartz is being tested to enable the company to decide as to putting in machinery to fully develop the property.

Emanuel Wilfong, Joseph T. Montgomery, Henry H. Thompson and Silas S. Parsons have been committed for trial next month on the charge of obtaining \$5,000 from Charles W. White, of New York, under false pretences. They sold White claims to two mining properties, having made false affidavits of discovery.

A vein of quartz carrying native silver and copper sulphide was struck by Alex. MacFarlane in the course of blasting operations on Banning street, in the town of Port Arthur, Ontario. The find is regarded as sufficiently rich to offer a chance for profitable working, and claims have been staked. — Arthur H. W. Cleve, superintendent of the British Mint, is on his way from London, England, to superintend the installation of machinery at the Mint to be established at Ottawa.

Mining Summary.

ARIZONA.

COCHISE COUNTY.

(Special Correspondence).—At Johnson Camp the Consolidated Mining Co., embracing the Mammoth and Republic group, continues to ship one car of ore per day. About 40 men, of whom 15 are Mexicans, are employed. The Dragoon Mining Co. is shipping about three cars of ore per week. Thirty Mexicans are employed. Mr. Johnson, who recently bonded the Mayflower claim, with no surface showing of ore, after prospecting by open-cuts through wash to solid formation, discovered an orebody. An incline shaft 40 ft. deep shows ore for 23 ft. which averages 8% copper. One car of ore was shipped from this work and further developments and regular shipments will be made as soon as timber arrives to take care of the ground which is unsafe. This is the largest strike made at this depth since the early days of the Peabody. L. Ezekiel is superintendent.—The Empire Copper & Gold Mining Co., owning 12 claims, is working eight Americans.—The Michigan & Arizona Co., operating on the Copper Chief group, is sinking a double-compartment shaft, which is at present 100 ft. deep. It has a good showing of ore in several shafts and inclines and some ore on the dumps. It is expected to encounter ore in the development shaft at a depth of from 300 to 600 ft. Superintendent Robt. Mackay of the Black Prince Co. is pushing development on that property.—The Cochise Copper Co., operating the easterly continuation of the Peabody group, is sinking a shaft on its property. It has attained about 150 ft. depth but is not yet through the wash which covers the formation at this point. There are numerous prospect shafts on this property, but it is said no ore of commercial importance is in sight as yet. K. L. Hart is manager and Leo M. Brown superintendent.

Johnson, Sept. 8.

The new copper smelter at Black Diamond is working smoothly. It has a capacity of 200 tons daily.—E. B. Gage, manager of the Tombstone Con. Mining Co., says the company has really a bigger undertaking than was calculated upon when operations on the old properties were resumed. But the machinery has proved equal to the undertaking, the water question has been disposed of and daily shipments to the El Paso smelters are made. These will be increased rapidly from now on, as the property can be developed much faster with the larger force.

GRAHAM COUNTY.

(Special Correspondence).—In six months ending March 31, 1906, the Arizona Copper Co. smelted 293,242 tons of first-class and concentrating ore. Of this output, 182,584 tons were obtained from the Longfellow group, 66,704 tons from the Metcalf group and 43,954 tons from the Coronado group, the proportion of first-class and of concentrating ores being 5.91% and 94.09% respectively. The average yield of all ores being 2.4% copper, 41.39 tons of ore were consumed in the production of one ton of copper. On the Liverpool tunnel level of the Humboldt mine, the settling of the ground is not so marked as it was six months ago. A severe side-pressure is still sustained by two stopes working above the adit level. Here the expense for renewal of timbers is very heavy. The ground suffers much from the inflow of rain-water. Arrangements are being made to provide better drainage and also better ventilation, the latter being a good corrective for swelling ground. In the drift running towards the Edinburgh level, an orebody has been cut, which looks like the extension of the Fairplay vein. In the first level of the Humboldt, at a point 450 ft. northwest of the Humboldt shaft, a drift has been extended from the main tunnel for a distance of 135 ft. in low-grade ore. As soon as the drift has been sufficiently extended, the character and extent of the orebody will be determined. The drift will be of use in tapping the northeast end of the Joy mine and in testing the Humboldt mine. West of the main shaft 850 ft., a stope has been opened directly under the Eagle stope and a second stope is being opened in the same ground. The ore is of good grade. On the second

level of the Humboldt, the drift is being extended as rapidly as possible to connect with the Yavapai and Joy mines. It is being run in close touch with a promising vein which was barren on the upper levels. This will serve as a base for the cross-cutting of the entire Humboldt claim at points where the ground still stands unbroken. It will serve also to tap a known orebody in the Joy mine which has been neglected because of its inaccessibility. About 1000 ft. southwest of the main shaft a stope is being opened on the main orebody at a point 50 ft. south of the main tunnel. Here the ore has opened out magnificently both in quality and quantity. At the King mine of this same company, the work continues by open-cut and stoping. In the second adit a cross-cut has exposed 12 ft. of sulphide ore at a point 80 ft. below the surface. On the third level work has been extended 200 ft.; beneath stope No. 3 a winze was sunk 70 ft. in good oxide ore, which at this low level changed into sulphide, showing a width of eight feet and carrying 14% copper. The fourth level is the lowest level of the Jamieson mine. It was extended to cut the King vein, which it succeeded in doing lately. Where found, the vein was 18 ft. wide, and carried 5% copper; it has been advanced 150 ft. farther in ore of poorer quality. The 500-ft. level of the Coronado mine of this company at Metcalf has been completed to the air-shaft, and was driven 220 ft. beyond that point. The vein was found to be continuous wherever it was cross-cut, and it averaged 30 ft. wide of pay ore. West of the air-shaft the drift ran into barren ground, just as it did on the 300-ft. level. The West shaft is now down to 700 ft. Copper stains were encountered in the diorite in which the shaft was sunk. The ground is now being cross-cut. The air-shaft was sunk to the same level in good ore to a depth of 650 ft. On the 700-ft. level the ore is 40 ft. wide, but it carries no more than 2% copper. From the main shaft the level has been driven 300 ft. Two cross-cuts have been made; the first, 90 ft. west of the shaft, exposed 48 ft. of ore carrying 2.3% copper; the second, 190 ft. west of shaft, exposed 23 ft. of ore carrying only 2% copper. In the concentrating department of the Arizona Copper Co., taking 180 working days in the half-year, the daily consumption of ore averaged 1,532 tons, as compared with 1,602 tons during the previous six months.

Morenci, September 8.

MOHAVE COUNTY.

W. H. Cushing, president of the Stockton Hill Mining Co., owning the De la Fontaine and Cupel mines, near Stockton Hill, says the mill on the Cupel is almost completed. At De la Fontaine mine a large force of men is at work and in all the openings lead-zinc ore is being developed. In the raises from the adit level big orebodies have been encountered, and in the lower drifts the ore shows improvement. The mine now has 100,000 tons of milling ore blocked out.

CALIFORNIA.

NEVADA COUNTY.

A number of San Francisco capitalists have become interested in the Union Consolidated mine, at Banner Hill, near Nevada City, and in order to finance the concern and pursue development work the company is to be reincorporated under the laws of Arizona. It is said a good body of ore has been found.

The old Blue Union vein was uncovered last Sunday, at a depth of 25 ft., in the bottom of the winze. It was known that the vein was there, and after securing a bond on the property, W. J. Howard, James Gluyas, and E. Dunkley put men at work to clean out the shaft. The vein is 18 in. wide, confirming the statements of old miners who worked in the Belle Union in 1872 when a sudden flow of water drove them out. Samples show gold.

TULUMNE COUNTY.

R. E. Dull recently took out a pocket of \$2,400 from his mine on Jackass hill, near Tuttletown.—The Crystalline group of mines, a mile northwest of Jamestown, has been bonded by C. E. Shafer to J. L. Chaddock, of San Jose, and W. H. Stenger, of Beaumont, Tex., who, under the management of C. W. Ayers, intend to develop the mine at a greater depth. The Crystalline is the second mine south of Table mountain, the first being the Alabama.

KERN COUNTY.

(Special Correspondence).—A. C. Bercham is developing a valuable property in the Phoenix mine, near Johannesburg. The mine was operated several years ago, but was not particularly successful, the vein being small and of irregular value. A new inclined shaft was sunk 200 ft. by Mr. Bercham, and levels opened at 100 and 200 ft. Driving easterly the ore has been found to be of better grade and has increased in amount, until, in places, there are from 4 to 12 ft. of payable ore. The vein has split, and toward the most easterly end there is 15 to 20 ft. of solid ore of good grade, with every geological indication of a further increase in amount of ore. The surface equipment consists of hoist, 5-stamp mill, with space and power for additional stamps. There is also a cyanide plant on the property. A compressor and additional stamps will be added to the plant.

Randsburg, September 8.

COLORADO.

GILPIN COUNTY.

(Special Correspondence).—The Running Lode mine, being operated by the Gower Syndicate, is reported ordered closed down by the stockholders. This mine has been one of the famous producers of the district. Dr. Gower organized a company several years ago and took active management of the property. For a time everything went well—as long as the ore lasted, but when that gave out the stockholders refused to come forward with money to seek another ore-shoot. A little work is being done at present, but it is understood will cease shortly. The Doctor has forsaken mining and gone back to his profession, as a teacher of music. At one time the stock sold as high as \$15 per share, but now there seems to be no demand at any price. A one-time stockholder in the concern stated that the property was run on an economical basis, so much so that the management did not like to pay good wages for good men, nor would it spend a dollar to develop the property. A story is told of the superintendent, who stated that he had been on the property for eight years, and never spent over \$25 in that time for assays on the mine. Of course when a carload of ore was shipped to the smelters they had a control which was not included in the \$25.

Black Hawk, Sept. 5.

SUMMIT COUNTY.

(Special Correspondence).—The increased activity of the camp of Breckenridge has, as yet, shown no signs of abatement, but new enterprises are starting up and many new discoveries being made.—George Hammerschlag, an old-time prospector and miner who has operated on Farncomb hill for many years, struck a six-foot body of high-grade gold ore in the Wilson property which adjoins the Wire Patch. Free gold is seen and some nice cabinet specimens have been obtained.—King and Hammel, who have a sub-lease on the Bullion-King property, have opened up a surface vein of rich lead carbonate over 18 in. wide.—The management of the Old Union Co. intends to install a dynamo for lighting their mill and the main levels of the mine.—The North American Placer ground, owned by the American Dredging Co., on Swan river, has been taken under bond and lease by Ben. Stanley Revett. Three churn-drills are now employed, sinking test holes to bedrock and when the richest channel has been found the Bucyrus dredge will be put to work.—The Reliance Dredging Co.'s big dredger on French creek continues to wash large quantities of gravel and is making good clean-ups.—At Swandyke camp much more work is going on this year than heretofore, generally. Ed Graw & Co. shipped 30 sacks of high-grade gold ore from a prospect and got returns of over \$300 per sack.—E. E. Young, manager of the Hoosier Creek Mining Co., has arrived at the mine and intends to resume sinking the main shaft. He expects to cut the vein, which was four feet wide at the 100-ft. level, by running a 50-ft. cross-cut from the 200-ft. level.—The Wilsley mine at Kokomo is having a new calcining furnace built in connection with its reduction works. It has been found that by roasting the concentrate from the Wilsley tables previous to treatment by the Magnetic separator, much cleaner and higher grade products can be obtained.—Montezuma camp is booming.

This district produces much shipping ore of high grade and with the installation of suitable mills would also produce a large amount of good lead and zinc concentrate.—Over 60 new locations have been made in the Horse Shoe district above Rathbone in the last 30 days.—The Lenawee Tunnel Co. has its new mill running on ore from the Fisherman mine, which it now holds under lease. The Fisherman has been a shipper of high-grade lead and zinc ores for many years and has in its main workings large quantities of mill ore, which assays 20% each of zinc, lead and iron and carries 8 to 10 oz. silver and \$6 gold per ton.—The extension of railroad communication from Denver to Argentine by the opening of the Wilcox Electric railroad has a tendency to open new territory on Argentine Pass.—The Waterloo mine is again in operation and a 10-ft. vein of zinc ore carrying lead and silver has been opened.—On Glacier mountain Bull & Rosengarten are driving an adit on the northern slope, which is now in over 300 ft. and contains a vein 18 in. to 2 ft. in width that assays 50% zinc. This property is expected to ship regularly from this time on.—The Rothschild tunnel is being steadily pushed ahead with machine-drills. It is now in over 3,600 ft., and has cut a vein of ruby silver at a depth of 2,400 ft. below the surface. Some of this ore assayed 19,000 oz. silver per ton.—Charles Campbell is operating the Clarion under bond and lease and is taking out ore which is high in lead and carried 400 to 500 oz. silver per ton.—The Braganza mine on Collier mountain has shipped a carload of quartz carrying yellow copper and running high in gold and silver.—The Pennsylvania mine is keeping up a steady production of shipping ore and concentrate which are loaded on the railroad at Keystone and shipped to Leadville and Denver via Breckenridge.

Breckenridge, September 8.

IDAHO.

SHOSHONE COUNTY.

The Nine Mile Co. will resume work on its property near Wallace. This decision has been hastened by the discovery of ore on the surface by O. H. Linn, superintendent of the Success Co., who is also manager of the Nine Mile Co. Work for the present will be confined to sinking a shaft on the vein. Extensive development has already been done in three adits which have not, however, reached that part of the vein where the new discovery was made.—The Samson Mining & Development Co. has let contracts for more development on its property on Big creek. W. J. Herring has taken the contract. The company expects to tap its main ore-shoot with this work. Rich copper and silver ore has been taken from the main adit which will now follow the main vein directly for the ore-shoot. The property has about 400 ft. of development. Work on the long adit of the Silver King mine, by which the ore-shoot of the Stewart will be tapped, has begun on a large scale, and Fred O. Merriam, the manager, has taken his residence at Kellogg to personally direct the work. The Stewart, Silver King and Crown Point properties were recently bought by F. Augustus Heinze.

MONTANA.

GRANITE COUNTY.

George H. Savage, manager of the Milwaukee Gold Extraction Co., in Red Lion district, has purchased a gasoline hoist for the Hannah mine. The directors of the company some time ago decided to sink a shaft to explore the Hannah to a depth of 600 ft. below the present workings, where it is believed that copper ore will be found. It is thought that the iron cap of a great vein covers a copper deposit. The shaft has reached a depth where hoisting machinery is necessary. Owing to the difficulty of supplying water for steam boilers near the top of the mountain, a gasoline hoist was decided upon. The ore now being treated at the company's mill, near the foot of the mountain, is being mined from an adit which taps the Hannah vein at a depth of 125 ft.—James M. Glenn, of Cincinnati, Ohio, has been for two weeks at his mine near Georgetown, and now has men developing the Orphan Boy and adjacent claims. He has opened up ore running from \$6 to \$20 per ton, and will start his mill for a test run on this ore.

MISSOULA COUNTY.

I. M. Cuschner, president, and William Dee, manager, recently visited the big Missouri Mining & Milling Co.'s property, one-half mile from Eddy, and 170 miles from Spokane, on the Northern Pacific. The company has 160 acres of placer ground on the banks of the Clarks Fork river. Miners are starting a cross-cut adit to cut the vein at 1,200 ft. depth. Vein No. 2 will be developed by a cross-cut from vein No. 1. The company will lay in provisions and supplies at once to last the full crew until May. The veins carry gold and silver.

NEVADA.

ESMERALDA COUNTY.

Every producing mine and every producing lease in the Goldfield district is closed down, according to press despatches, as a result of the meeting held by the miners on September 10, at which they decided to support the Industrial Workers of the World, an organization of unskilled laborers that seeks to dominate the labor situation here. The holders of leases who have closed down have the assurance of the mine owners that their time will be extended for as many days as they are now closed down. The Industrial Workers of the World began the present trouble by boycotting a local paper and threatening to boycott everybody who patronized or advertized in it. On the night before the Gans-Nelson fight an employee of the paper was forcibly taken out of town and left on the desert, with orders to keep going. Prominent mine owners went after the man and brought him back. The mine owners expected the trouble would end yesterday, when 12,000 miners met at the fight arena to decide whether their organization would continue to support the I. W. W. The mine owners thought their employees would repudiate the organization, but the miners voted to stick to their original stand. Feeling is intense, but it is believed that calm counsel will prevail and that the trouble will soon be straightened out.—The books of the Miners' Union at Goldfield show that of the 2,000 workmen in the district, 1,400 are on the day shift. The payroll is about \$300,000 per month. There are more men at Goldfield now than at any other period in its history.

LINCOLN COUNTY.

(Special Correspondence).—With the advent of cool weather, many men are coming into Searchlight. New companies are preparing for extensive development work upon their properties, and several of the older companies that reduced their working force during the summer are now operating with three shifts and an increased force.—The Duplex Extension Mining Co. is to let contracts to sink a double-compartment shaft to water level on the Regal claim. The vein can be traced from the Duplex mine, and the surface showing is promising. George McClintock, of the Searchlight Bank & Trust Co., has been added to the directorate of the Duplex Co. — A merchants' association was organized in Searchlight during the past week, to improve the commercial conditions of the camp. One of the first matters taken up was the installation of a water system for fire protection. A 50,000-gal. tank will be erected upon Granite hill overlooking the camp; mains will be laid along the principal streets and hydrants placed at short intervals. — The management of the Cyrus Noble Mining Co. has inaugurated a new system of treating the ore. Heretofore the returns from the mill have not been satisfactory. Concentrators will now be added to the mill equipment. — The Searchlight Vanina Mining Co. is prospecting its Dorothy group and will sink a working shaft. The property is situated west of the Searchlight Mining & Milling Co.'s mines. Development work will be under the supervision of John Howe, who has charge of the Searchlight copper-gold mine, on Copper mountain. — H. B. Adsit, manager of the Colorado Mining & Milling Co., reports having struck a large body of oxidized ore at a depth of 74 ft. in the shaft on the Grey Ghost claim, which is being sunk to water level. The orebody encountered does not outcrop on the surface. — The Stone-Brown Co. has acquired the Gold Sovereign group adjoining the east end lines of the Southern Nevada Co. The property was bonded from the original locators. The conditions of the bond call for extensive development work within one year. There is

a large vein in a contact running east-west on the Gold Sovereign claim. — The Southern Nevada's Hi Hu vein strikes diagonally across the Camp Bird claim, and the Euclid vein can be traced into the Annette. A three-foot vein of copper-stained quartz carrying a narrow streak of high-grade ore traverses the Gold Link claim, and the first shaft will be sunk on this vein.

Searchlight, September 8.

NEW MEXICO.

Regarding mining conditions throughout New Mexico, T. A. Jones, in the Santa Fe *New Mexican*, says that the Carpenter district in Sierra county is again producing zinc and lead, and the Magdalena district is among the big zinc producers of the country. Tres Hermanos district, 25 miles south of Deming, shows considerable development in zinc properties recently found. There is renewed life near Estey City, in the southeastern part of the Oscura mountains. In the San Andres mountains copper properties are being developed by Eastern capitalists, who are making a good showing. These are in Socorro county. The Lordsburg mining district is shipping from three to five carloads of ore per week. The ore of the Lordsburg district is mostly silicious and heretofore has been costly of treatment. Freight rates on this class of ore to the Douglas and El Paso smelters have been reduced, which has enabled mine owners to get to these smelters with their ore and receive higher net returns.

OREGON.

BAKER COUNTY.

Wood & Wandersee have a shaft down 70 ft. on a quartz claim near Sumpter. It is reported that good gold ore has been found there in a cross-cut — W. H. Heath, the superintendent of the Standard mine at Quartzburg, contemplates some changes in the mill at that property.

SOUTH DAKOTA.

LAWRENCE COUNTY.

In the neighborhood of 50 carloads of ore are hauled daily from the Bald Mountain district to the mills at and near Deadwood, and this quantity will be increased by a new night train. This ore is from Terry and Portland, from 20 to 24 carloads per day coming from the former, and from 20 to 26 carloads from Portland.

PENNINGTON COUNTY.

A. C. Baxter, of Lima, Ohio, one of the principal stockholders in the Dakota-Calumet Copper Mining Co., says the Dakota-Calumet has installed a new power plant with increased capacity. Formerly the company had but 300 h.p., but has added 200 more by the installation of a large boiler. A centrifugal pump to handle the sediment, and a station pump were added to the equipment. Work is being carried on below the 300-ft. level. A. C. Overpeck is manager. The Dakota-Calumet adjoins the Blue Lead Copper property, near Sheridan.

UTAH.

BEAVER COUNTY.

Reports from the Cactus properties of Samuel Newhouse are to the effect that there has been material improvement both in mine and mill, during the past summer. The mill has been running for more than a year, and the percentage of extraction has been steadily increased, until there remains little to be desired. The mill is treating from 850 to 900 tons of ore per day, and the saving is between 80 and 85%. Under the superintendency of C. D. Moffatt the mill is in excellent condition, the concentrate being shipped to the smelters of the American Smelting & Refining Co. at Salt Lake. The concentrate is running 15% copper, in addition to gold and silver.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The Oversight Mining & Milling Co. has made a discovery of gold-bearing quartz at the base of Missouri mountain, about 700 ft. west of its No. 2 adit. Samples of the ore taken from four places assayed respectively \$12, \$25, \$60 and \$61. This ore differs from any other ever found on the Oversight group. It carries little iron and contains cobalt in commercial quantity, in addition

to the gold.—Members of the Belcher Co. recently visited the Belcher mine. The president reported that the No. 4 adit, the last started, is running on the vein and will be under the workings of the No. 3 in about 500 ft. He also says the Belcher mine will begin shipping ore as soon as the Belcher mountain railway finishes the laying of rails. The company has decided to construct a gravity tramway from the upper adit to the ore-bins below, a distance of 2,200 ft. While the Belcher has a large vein, no stopes have yet been opened, and the small force employed indicates that little preparation is being made for stoping.

Republic, September 8.

SPOKANE COUNTY.

The fight between the Inland Empire Co. and the Consolidated Smelting Co. for a right-of-way out of Spokane down the river has disclosed the fact that the latter company has purchased the right-of-way and plant of the old smelter company, which built but never operated a smelter seven miles down the river from Spokane. This was built many years ago, and at one time Robert G. Ingersoll was chief stockholder. It seems the Consolidated Smelter Co. has now acquired the property, and proposes to rebuild and operate the plant. Philadelphia and Grand Rapids people are largely interested. The Graves people are trying to condemn a right-of-way over the same route.

STEVENS COUNTY.

(Special Correspondence).—The Metaline district continues active and much work is being done. The Stirling Silver-Lead Co. is constructing a ditch to take water out of Sweet creek and develop about 2,000 h.p. with a 250-ft. head. The Larsen Lead Co. is expecting to use this power at its concentrator, for which the ground is being broken. The latter has taken an option on the Roi Clark claims, at the mouth of Flume creek, on the west side of the Pen d'Orielle river, and is employing 12 men in prospecting and putting up buildings for a camp. — The Metaline Mining & Smelting Co. is employing six men underground. — A five-foot vein of silver-lead ore has been opened by an 80-ft. adit on the Bella May mine, and 30 tons of ore have been shipped up to the present time.

Colville, September 8.

WHITMAN COUNTY.

The Hecla Copper Mining Co. has been incorporated by J. C. Northrup, C. E. Frederick, D. G. Klinefelter, W. F. Chalenor, G. N. Lamphere and W. R. Belvail, of Palouse. The company is formed to develop the Hecla group of claims in the Hoodoo mining district, 35 miles east of Palouse. Since the advent of shipping facilities, furnished by the Washington, Idaho & Montana railroad, the Hoodoo mining camp has taken on new life. There are now 40 men at work there.

CANADA.

BRITISH COLUMBIA.

The Hall Mining and Smelting Co., Ltd., states that owing to increase in the shipments of ore, and the shortage of labor, it is behind with the unloading of ore, and for some time past has been under expense for demurrage. A few days will be required to make some changes in the sample mill, which will increase its capacity, and the company therefore asks shippers to defer making further shipments for a time. For the past five weeks the Nelson smelter has undertaken to handle the whole output of the St. Eugene mine to enable the Trail smelter to make some alterations.

The output of ore from the Boundary mines for the week ending September 8 was as follows: At Phoenix, Granby mines, 13,932 tons; Snowshoe mine, 870 tons; Brooklyn-Stemwinder mine, of the Dominion Copper Co., 2,211 tons; Idaho mine, 330 tons; Rawhide mine, 792 tons; Sunset mine, at Deadwood, 729 tons; Mountain Rose, at Summit, 40 tons; Oro Denoro, at Summit, 231 tons. Total for week, 19,135 tons. Smelter treatment during the same period: Granby Co., 16,320 tons; Dominion Copper Co., 4,102 tons. Total, 20,422 tons.

YUKON.

There is good reason to believe that the amount of gold brought down to Seattle from the Klondike district will greatly increase during the next few years. At present

dredging is the most prominent feature of mining on the Klondike, and there are six gold dredges in operation in the district. The next season will witness a fleet of a dozen dredges in operation on the Bonanza, Klondike and Forty-Mile streams, provided American manufacturers can supply the demand for this class of heavy machinery. The gold output will be correspondingly increased. It is to the credit of the Canadian Government that during the years succeeding the Klondike rush they have expended close on \$1,500,000 for the construction of roads and trails, and more than \$75,000 for the improvement of the Yukon river and its tributaries. There are many Americans in the Territory, and the Canadians seem glad to have their cousins from below the boundary line to assist them in developing the great resources of that vast territory.

MEXICO.

CHIHUAHUA.

The Mary Mining Co., of Pittsburg, is opening up three *antiguas*, or abandoned mines, at Tojiachic, in western Chihuahua. The ore is high grade and suitable for smelting, so that a smelter is to be built shortly. Dr. Leandro Routh is local manager. — A company organized by Bernardo Garcia, the promotor of Lluvia de Oro, has taken over the Cocineros, Concepcion, San Joaquin and Natividad mines in the Santa Eulalia district, the Donato Gueria mine at Parral, and the Independencia group at Santa Lucia. The organization is made of local people and the properties are considered promising.

GUANAJUATO.

The Guanajuato Reduction & Mines Co. is now treating 250 tons of dump ore daily. A tube-mill for re-grinding the ore has been placed in operation. The unwatering of the old mines of the Valenciana group is in progress, and as the water is lowered better grade ore is found. The milling of the lower grade dump ore will be soon discontinued in order to allow the handling of the richer ore from the mines. The Peregrina Mining & Milling Co. is rushing work on its 100-stamp mill in this district. It is expected to have 40 stamps dropping within a few days, and the remaining 60 stamps will be ready for operation early in September.

M. E. and Bernard MacDonald, the well-known mining men of this district, have organized the Mines Selection Co. with the object of securing developed Mexican properties and turning them over to other interests. The company will not confine its operations to any particular district or districts, but will handle developed properties in all parts of the Republic. The MacDonald brothers last year arranged the sale of the famous Real del Monte mines in the Pachuca district to the United States Smelting, Refining & Mining Co., of Boston. They are generally understood to bethe parties who recently secured an option on La Blanca mines in the Pachuca district for \$12,500,000. It is believed that La Blanca mines will be also taken over by the United States Smelting, Refining & Mining Company.

JALISCO.

W. M. Mathews, general manager of the Santa Domingo mines in the Hostotipaquillo district of Jalisco, states that the Santa Clara tunnel had cut the vein, exposing ore rich in silver sulphides and native silver. The work of driving the tunnel has been in progress for several months, the vein being cut at 140 ft. A shaft on this property has shown ore running from \$100 to \$150 per ton. The San Domingo Mining Co., of St. Louis, which owns the mines, has increased the working force under the direction of Mr. Mathews to 75 men, and has raised the appropriation for development work to \$1,500 monthly. Six adits are now being driven. The Santa Clara is one of the number, and the others are the Guadalupe, El Mono, Trinidad, Esperanza and San Pedro.

SONORA.

Las Chispas mine is in a healthy condition. Development work has reached the 800-ft. level and rich ore is being broken. The best of it is sent to the smelter at El Paso and the low grade is treated in a 10-stamp mill. Monthly returns are said to average \$500,000 Mexican. The product is chiefly silver, with some gold. The mine is 14 miles southeast of Arispe and the property covers 500 acres. The sole owner lives in Switzerland.

Personal.

S. S. SORESENSEN is at Oakland.

THOS. H. LEGGETT is in Siberia.

J. E. SPURR is at Velardena, Mexico.

A. J. CLARK has returned to Denver from Los Angeles.

GILBERT J. ROOTE is at 1260 O'Farrell St., San Francisco.

LESTER JACKSON has returned to Prescott, from Mexico.

E. J. MCCAUSTLAND has returned to New York from Europe.

A. B. WALLACE is in charge of an assay office at Seoul, Korea.

OWEN JOHNSON was married at Victor, Colorado, on August 22.

WALTER P. JENNEY'S address is now Box 696, Tonopah, Nevada.

W. R. FELDTMANN has returned to London from Western Australia.

LESTER W. STRAUSS is on his way from New York to Lima, Peru.

W. J. BELCHER is investigating mining property at Goldfield, Nevada.

WILLIAM BAILEY has returned to Los Angeles from a trip to Europe.

THOS. RICKARD, of London, has returned from a visit to St. Petersburg.

DENNY BROS. have opened an office at 564 Salisbury House, London.

W. F. CALVERT is examining dredging ground on the Unuk river, Alaska.

W. H. HEATH, of Baker City, Ore., has gone to Denver on mining business.

WM. A. HEWITT has returned to San Francisco from an extensive Eastern trip.

JOHN S. JONES has returned to Prescott, Ariz., from an extended Eastern tour.

E. G. DENNISTON, of San Francisco, has gone to Chicago and will visit New York.

WALTER G. PERKINS has returned to Ely, Nevada, from a visit to Salt Lake City.

WALTER P. JENNEY has changed his address to P. O. Box 696, Tonopah, Nevada.

CHARLES C. JONES has returned to Los Angeles from Panamint district, California.

C. D. EMMONS has returned to Seattle from examining mines on Queen Charlotte Island.

F. P. SHERWOOD is manager of the Guadalupe Mining Co. at Inde, in Durango, Mexico.

PETER T. AUSTEN, of New York, is re-modeling the Rigby reduction works at Mayer, Arizona.

ROBERT H. RICHARDS, on his Western trip, made professional visits in Colorado and Missouri.

DONALD F. CAMPBELL, who is with the Mountain Copper Co., is on a visit to San Francisco.

HORACE J. STEVENS has recovered from illness and is at work on his annual handbook on copper.

J. SULLIVAN has taken the position of foreman at the Soulsby mine, at Soulsbyville, California.

CHARLES D. AKERS is superintendent of the Happy Hollow mine near Downieville, California.

J. D. WOOD, of Salt Lake, has been appointed manager of the Thompson mine at Park City, Utah.

C. M. FULLER has returned to Denver from a trip through Georgia, Alabama, and other southern States.

W. C. HOWARD has returned to Los Angeles from his mines on the Colorado river, near Gold Roads.

FAYETTE A. JONES, of Albuquerque, New Mexico, is examining the placer beds near Cerrillos, New Mexico.

CHARLES E. HALL, of Mexico City, has been examining the Santo Domingo mine in the Etzatlan district of Jalisco.

Books Received.

DICTIONARY OF ENGINEERING TERMS in English and Spanish by Andres J. R. V. Garcia. This is a handy little book of 150 pages giving 3,000 technical terms in English and Spanish, to which is added a serviceable index in both languages. Mining engineers and operators in Mexico and South America will find the book a useful companion. Published by Spoon & Chamberlain, New York, and for sale at one dollar by the MINING AND SCIENTIFIC PRESS.

MICA AND THE MICA INDUSTRY by George Wetmore Colles. This is a monograph originally published in the *Journal of the Franklin Institute* and subsequently revised and enlarged by the author. It is a neat little book of 130 pages and affords a discriminating compilation of all the latest information on mica, including the mineralogy and geology of the mineral, the geographical distribution, mining and milling, its uses and statistics. Owing to the increased use of mica, this volume should prove valuable to engineers and to manufacturers. Published by the Franklin Institute, Philadelphia, and for sale at \$2 by the MINING AND SCIENTIFIC PRESS.

THE CALIFORNIA DEBRIS COMMISSION HAVING received applications to mine by hydraulic process from Lost Channel Mining Co., in Lost Channel Mining Co.'s Claims, near Cromberg, Plumas County, Cal., draining into Jackson Creek; and from J. S. Goodwin, in Nevada Mine, near You Bet, Nevada County, Cal., draining into Greenhorn Creek, gives notice that a meeting to receive any protests will be held at No. 1733 Pine St., San Francisco, Cal., October 1, 1906, at 1:30 P. M.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

WHEN pump valve-seats are badly worn a disc of sole-leather clamped to the hard rubber valve is often of service.

THE failure to cross-cut the country on either side of a vein has caused many an otherwise competent miner to overlook a good orebody.

IT is often the case that streaks of ore occur within a vein, crossing it or lying in such a position as to suggest their secondary origin. Such ore may be wholly unlike the main mass, and is often much richer.

CHROMIC IRON, pyrite, magnesite and manganese oxide are all salable in California, but to be commercially valuable these minerals must occur in a situation easily accessible to cheap transportation to the markets.

THE strongest exploders for dynamite always produce the best results, for the reason that they effect a more instantaneous and complete explosion of the nitro-glycerine in the powder, breaking more rock and creating less gas than when the lower grade exploders are used.

ANY sandstone, or other building stone, containing much pyrite will not prove to be durable, as oxidation of the pyrite will in all probability result in at least a partial disintegration of the stone. Stratified building stone should always be laid in the wall with its bedding parallel to the horizon, and never set on edge, where the stone is required to sustain much weight.

THE use of steam-shovels would be justified in many places where they are not employed. The cost of operating a steam-shovel can be readily ascertained. It then becomes a question of comparison with other methods of handling rock, whether it be waste or ore. It should be remarked, however, that the steam-shovel is seldom economical in a small operation.

IN making comparisons of various mines, not only the amount and value of the ore available must be considered, but also the environment of the mines under consideration, for an orebody of given dimensions and value per ton may pay handsomely in one locality, where a similar ore elsewhere may be commercially valueless, owing to disadvantageous situation.

THE ore in a caved stope may often be recovered by one means or another. In some instances it may be drawn directly from the caved ground by first excavating an approach for chutes and working place in the solid country rock adjoining the cave; in other cases the ore may be allowed to run down into a stope opened below, the waste ore being separated, at some convenient place, should this be necessary or advisable.

IT is generally considered unsafe to accept the proffered aid of the owners of a mine, or of those in any way connected with the sellers. The cautious engineer usually takes his own men with him, and insists on doing his work in his own way unaided by strangers. Such conduct on the part of the examining engineer may give offense to the other party, but it is generally acknowledged the safer plan to refuse all unsolicited aid.

AT the last special session of the California Legisla-

ture the measure which provided that assessment work on unpatented mining claims be not required for the period of one year on account of the loss to the mining interest occasioned by the San Francisco fire, and which was adopted by both houses and forwarded to Congress, failed to receive a hearing in that body. All claim owners will be required to do their \$100 worth of assessment work as usual.

IN deposits of copper-bearing ore, there is often little or no indication of the presence of this metal in the outcrop. The Peacock mine, in the Lava Beds district, San Bernardino county, Cal., is an instance. The outcrop is highly silicious, iron-stained, and carries from 10 to 80 oz. silver per ton, while barely a trace of copper can be seen. In depth, however, bornite with 15 oz. silver per ton, was found to be the prevailing ore, and the property was worked for its copper rather than for the silver.

LIGHT TIMBERS may be used in square-sets, where the ground stands well for a time, if filling is promptly placed as stoping progresses, but it must be remembered that a rock stope only partly filled affords support to the walls, or superincumbent ore, only where actually in contact with the overhanging rock mass. The mistake most commonly made is that of attempting to extract ore from too large a superficial area. Stopes in large veins should be carried upward in the form of a pyramid, relatively high and narrow, and not broad and flat. If the vein be very wide—more than 100 ft.—it is usually the best practice to carry the stopes in comparatively narrow section longitudinally of the vein and extending from wall to wall.

TO MAKE a matte direct from copper ore, the latter should contain 15 to 16% sulphur. With a 4% copper ore, it would certainly be best to concentrate—if the ore is amenable to such treatment—then roast the concentrate, leaving about 8% sulphur in it, and then melt it down in a reverberatory with gas fuel. The use of wood as fuel for smelting is practicable, but wasteful. It would be better to make fuel gas and apply the latter direct to the matting furnace. Local conditions and the composition of the ore will determine the best course of action. In any event, before going to the expense of a smelter or a concentrator, or both, it is the part of wisdom to get expert advice, both in the choice of a process and in the erection of the plant.

CALCIUM OXIDE (quick-lime), in suitable amount, 5 to 10 lb. per ton of ore, is often employed in silver mills, to counteract the influence of manganese-oxide. The Calico ore probably contains the black oxide of manganese, and not 'magnesium,' as stated by our correspondent. It is very difficult to avoid loss of mercury where treating ore containing manganese oxide. Where lead and zinc sulphide are obtainable, it is good practice to mix the manganese-bearing ore and the sulphide ore, treating them together. When manganese oxide is present the bullion produced is generally finer (higher grade), than where there is no manganese in the ore. It is probable that the treatment of manganiferous ore in pans releases oxygen from the manganese which it is thought results in the formation of a suboxide of mercury. It might be worth while to endeavor to recover some of the mercury by discharging the tailings into conical hydraulic-classifiers, conducting the slime to a tank and allowing it a long time to settle. It is not uncommon to find considerable mercury at the bottom of the settling-boxes beneath vanning machines which contain only the finest slime floating from the washing box, consequently these globules of quicksilver must represent the accumulation of floured quick.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Vein Mining in Alaska.

The Editor:

Sir—I note with pleasure the attention which my communication in the issue of May 12 regarding 'Vein Mining in Alaska' has received by so competent an authority as Mr. William M. Brewer. I am especially grateful to Mr. Brewer for enumerating several of the metalliferous lode properties now coming into prominence in the South Coast Province, concerning which he has had opportunity to acquire recent information. My previous letter was rather in the nature of an enquiry for the facts than an attempt to decry the unquestionably large mineral resources of Alaska.

I have followed with no small degree of interest the development of quartz-mining in Alaska since the year 1895, when it was my privilege to visit the mines of Silver Bow Basin, Berner's Bay, Sheep Creek Basin, and other points of the Alexander Archipelago. In 1904 when I again made an inspection of Silver Bow Basin, matters had not progressed to any considerable extent in the way of lode mining. Two small mills were operating, and there was the same talk of great prospective developments in the region round about, that I had heard nine years before. The wide belts of stringer-leads in the black slate have always offered the suggestion that large low-grade orebodies might sometime be developed. The Alaska-Perseverance will probably provide ore for its 100-stamp mill from this character of material. The continuous and profitable operation of so large a mill in Silver Bow Basin will be a source of gratification to those interested in Alaskan development.

Perhaps a more just criticism of my paper than that of the pessimism charged by Mr. Brewer, would be, in the case of the Prince of Wales copper deposits failure to note the increase of production during the present year. I should be very glad to be kept informed of the progress made in that region by means of the mining press. No recent data excepting those given by Mr. Brewer have come under my eye.

So far as unfavorable conditions for prospecting are concerned, I tried to make due allowance for such in referring to the Alexander Archipelago and adjacent portions of the mainland. It is not easy to find rock exposures in that part of the country. The islands may, however, be circumnavigated in small boats at certain times of the year without great personal risk. As for the country farther west, numerous prospectors make a practice of exploring the coast in dories. I have personal knowledge that the whole south shore of the Alaska Peninsula from Cape Douglas has been so prospected. In 1895 I formed one of a party that cruised these waters for some 600 miles in a 40-ft. tug-boat, and spent one whole day contending with the tide-rips of Turnagain Arm in a sea-otter boat, and there was no serious danger or discomfort attendant on our movements.

In regard to the personnel of the Alaska prospector, he comes from many places. One of the best prospectors I have ever known was born on the Massachusetts coast; another was formerly a fisherman in the Bay of Naples. But from whatever interior community he may hail, average judgment and intelligence should teach him to handle a boat after a brief period of tuition.

There is every indication that the Copper River copper deposits will in due time produce considerably. And I should perhaps further emphasize my previous state-

ments regarding the McKinley range. This range is high and difficult of access. Along and adjacent to a line 100 miles to the north-northeast, and 200 miles to the south-southwest, of Mount McKinley, ore deposits, principally valuable for gold and copper, should be found. In a parallel direction and following the head of the Chulitna, tributary to the Kuskokwim, I believe that extensive deposits of lead ore with values in silver and lead occur, but whether of marketable worth or not it is impossible to say.

C. W. PURINGTON.

Denver, Colo., August 23, 1906.

Who Is a Mining Engineer?

The Editor:

Sir—Speaking of 'Mining Quacks,' whom 'Viator' castigates so forcibly in the issue of August 4, brings us dangerously within the range of the old proverb, that people who live in glass houses should not throw stones.

There are two points prominent in the college man's career.

First, for the years spent in acquiring instruction and training at the school, he pays out his own money. This is but the beginning of the education.

Second, after he leaves college, the investing public gives him the opportunity to acquire practical training at its expense. The right therefore to judge of the fitness of the subject, to have the legalized ownership of the title 'Mining Engineer,' with its honors and emoluments should lie with the investing public. The difference between the profit and loss on operations, conducted by the subject, to the credit of the latter, should constitute the examination necessary to prove fitness. If failures are made, they should be judged by the amount of work done for the funds expended in a judicious manner. The findings, if it can be proved that the failure was the result of no fault on the part of the subject, should go to his credit. In conducting an examination of this nature, the practical mining man, with no technical training, should be entitled to recognition, according to results achieved, with the same rights as the college man receives.

I live in a district where 90% of the failures recorded in mining can be laid at the door of the college man. Undoubtedly in other mining camps the same showing is made. Measured by the above plan of examination, there will be numerous gaps in the profession. It would be well-nigh impossible to say who are quacks or who are not. Mining is a dollars and cents proposition, in which it differs from the practice of medicine. That is a life and death proposition, and we have not got to the stage of perfection in finance, where we safeguard our pockets similar to our lives.

I fully recognize the advantages of a college education; it is the boiled-down experience of practical people in the profession, placed in a form for assimilation through hard mental effort. The courses of study taken give an advantage to the student, over the practical man, in this particular only, namely, the student gains in knowledge in a short period what the practical man often spends a lifetime of practical service in the effort to acquire. Against this, the practical man only studies the subject matter necessary as required, while the student gets the knowledge before being able to put it to use. As for the mental training, it is my opinion that the practical man who rises above the ordinary in the profession, gets his mind fully as well disciplined. It is a course which no college can give to the same advantage. There is little room for conceit on the part of the college man with a degree. Viewed in the light of results secured for the

investing public, it is hard to judge which side of the controversy has the best of it.

In regard to the term 'mining quack,' there is one particularly pernicious example to be spoken of. 'Viator' wishes to identify the breed by the giving of the letters M. Q. Two more letters should be prefixed—G. T. (Globe Trotting). More often than otherwise the particular quack of which I speak is a college man with a string of letters tacked on to his name for all the societies in the world. Such men make it a business of examining properties all over the world, and the ease and celerity with which they size up economic and mining conditions that puzzle the heads of old residents familiar with them, is astonishing. They presume to be competent to give advice to intending investors on transportation, labor, mining, and other features, in periods of from three days to three weeks sojourn in the districts examined. They probably never saw the country before, and can have no realization of the nature of the intricate problems on which they are to give advice. These men are the egoists of the profession. Every country suffers from their operations and snap judgment, and if the term 'mining quack' is to be handed around, they can fully qualify for the label. There are good men, but, from my own practical observation they seem to be mighty scarce. The good are generally specialists in certain metals. The rest might be classed as 'jacks of all trades.'

The writer is a newspaper man, who never examined a mine for pay, who would sooner risk his own dollars in an investment any time, than recommend one to the innocent public. Observation has turned his mind into a sifting machine, for the separation of the good and bad in the industry. Profitable results to investors is the basis from which to figure, and that is the only true basis from which should come the judgment as to who should, and who should not, be called a 'Mining Engineer.'

GEO. HUSTON.

Sandon, B. C., August 18, 1906.

[This letter is discussed in our editorial columns.—Editor].

Concerning Foremen.

The Editor:

Sir—In a late issue of your valued paper a correspondent indulged in playful criticism of the extract you printed from 'The Business of Contracting,' on the selection of a foreman.

I agree with his ideas in some respects but believe he did not read carefully the article he criticised. For instance the following paragraph:

"If he is worth keeping for a third job he is likely to have in him qualities which will lead to his being safely intrusted with more important work, or which will enable him to secure backing to go contracting for himself."

If your correspondent read that paragraph carefully he might have omitted some of his remarks. In his letter he says practically the same with reference to a foreman going in for himself. He is like too many people who confuse the foreman with the superintendent. In my little pamphlet the difference between the two positions is clearly shown. Each has a chapter to himself.

Your correspondent believes every man in charge of men is a foreman. I confine the term to a man controlling one gang. The man in charge of a job, with foremen under him, is a superintendent. He furthermore declares that such men are born and not made. That is an old-fashioned belief. The wonderful industrial advances of today tax severely the world's output of 'born' foremen. Consequently they must be made. Made they are in great numbers and the manufactured article is fully as good as the natural.

The drunken foreman of olden days finds he is no longer wanted. The supply of clear-headed trained men is not great enough to be encouraging, but nowadays contractors will risk a green man sooner than they will risk the 'born' foreman who goes on sprees.

ERNEST McCULLAUGH.

Chicago, August 31, 1906.

Who Is a Mining Engineer?

The Editor:

Sir—Your article on this subject appearing in a recent issue of your paper is well founded. Allow me to make some comments, which I think timely:

There are many people who term, or style themselves, mining engineers. From whence and how they hold these titles is a conjecture. Some possibly by paying stated dues to some society of mining engineers. Mining itself has many ups and downs, and is well seasoned with fraudulent schemes, intentional or otherwise, and these conditions have an influence on the manipulator in the industry, be he owner, shareholder, mining engineer, superintendent or foreman. But, I wish to dwell only on the legitimate side of the question: 'Who is a mining engineer?' and of the conditions now prevailing.

First, we must define the term, a mining engineer. He should be an intelligent person, of sound judgment. He should understand mining and have served in all capacities in different mines under different conditions and in various districts. He should also be competent to make surveys and assays, have an intimate knowledge of geology, and move with the times in all progress made in the arts and sciences of modern mining. Too many technical young gentlemen appear upon the arena, lacking practical experience, or the proving of themselves in their profession. These young men are intelligent, it will be granted, and deserve consideration and patronage at the hands of their seniors. They are the future of the profession for the coming generation in the mining industry. But, I find a good many of these young men in various capacities, as consulting engineers, mine superintendents, or as engineers in control of mines, where more mature experience and counsel is sometimes the pivotal point between failure and success. We find other of these young men throughout the East holding forth in well-appointed offices, with the badge of a college education and certificate of M. E., ready to give expert opinion in any and all matters affecting mining affairs, from chemistry to business management.

Young men may be graduated from reputable schools as doctors and lawyers. But, the graduation certificate does not necessarily make these men doctors or lawyers. There are just as many incompetents in these sister professions as in mining—the only difference being that they are licensed to practice, and so long as they do not commit crimes against society they are permitted to go on throughout their career without other annoyance than the fear of being found out. It is true, mining engineers are not licensed by the State, they may be required to register, but I mean the badge of efficiency is not given or required. It would be well if some standard could be reached, but alas for the frailty of human thought and action, I fear there can only be the one test, and that the one of duty well done with honesty of purpose. The interests seeking such services will have to pay to find them out, and not finding them, will suffer the consequences of the failures due to the hazard of mining when pursued as a sort of Alladin's Lamp flash to wealth. But, a better day is dawning. Let us hope so.

E. RAMMELMEYER, M. E.

Boise, Idaho, August 18, 1906.

The Refining and Toughening of Impure Bullion.

In the *Transactions* of the Institution of Mining and Metallurgy, T. K. Rose has a valuable article giving the results of his investigation on the refining of impure gold residues or bullion. This, together with the discussion of the subject by various members of the Institution, has been summarized.

In this connection 'refining' means the method of removing impurities or base metals from gold or silver bullion, while 'toughening' may be defined as the removal from high-grade bullion of small quantities of the impurities which make it brittle. Toughening, therefore, is but a final stage of refining.

For the oxidation of these impurities, nitre has been quite commonly (and successfully) used, the chief objection being the corrosion of the plumbago crucible by the nitre, and the losses which result from the method—running to as large a figure as 10%, mainly due to mechanical causes. Commonly the nitre has been put upon the top of the metal after melting in a crucible, the oxidized impurities then being taken up by a borax-and-silica slag. With the finely divided zinc-box slime, nitre has been mixed, with the idea that less loss would result. The losses, however, have been so great that the mills have shipped away the impure bullion at a reduced price, such, that for the lower grades, there was a difference of 40 cents per ounce. This low-grade product has also been difficult to sample and assay because of its irregular composition. The table herewith shows the composition of acid-treated and calcined or roasted zinc-box slimes:

	I.	II.	III.	IV.	V.
	%	%	%	%	%
Gold	34.0	36.1	37.3	49.8	4.4
Silver.....	4.3	3.5	3.7	9.5	
Zinc		7.5	6.2		39.1
Zinc oxide.....	22.5			0.2	
Lead		20.8	20.0	3.0	
Lead oxide.....	15.6				
Copper.....		2.5	2.5		
Lime (CaO).....					20.5
Silica.....	7.5	12.6	16.2	15.6	6.0
Sulphur trioxide	6.8	6.3	13.7	11.3	6.5

These precipitates are:

- I. Acid-treated and roasted gold slime from the Robinson Deep Mining Co., South Africa.
- II. Acid-treated slime from the East Rand Proprietary Mine, South Africa.
- III. Same slime after roasting.
- IV. Acid-treated and roasted slime from the Brodie works, Cripple Creek, Colorado.
- V. Slime from the Mercur mine, Mercur, Utah. This slime contains 36.7% calcium carbonate.

Ordinary zinc, such as is used for gold precipitation, contains upward of 1% lead, a small quantity of carbon and other impurities, as arsenic and antimony, which of course find their way into the slime.

Treatment of the slime: The acid-treated (or even untreated) slime is mixed with molasses or pitch, so as mechanically to bind the dry powdery precipitate together, and this, upon charring, cokes to a sponge or skeleton of carbon, having the effect of keeping the particles together, and of permitting the evolution of metallic zinc vapor entirely free from gold, as well as exerting a reducing action on any zinc oxide that might be present. This is charged into a black-lead crucible and the temperature brought up to a yellow heat, or to the distillation point of zinc. The crucible is covered with another old inverted crucible, forming a hood with an opening at the side having a lid. At the high temperature a flame of zinc issues from this opening, the lid being partly displaced. When the flame has died out, a mixture of borax and sand is introduced through the opening of the hood. When this has melted, and after about 15 min., a clay pipe half-inch exterior diam. by 24 in. long,

having one-eighth inch bore, is introduced through a hole at the top of the hood, extending down into the metal. Compressed air, in a regulated stream, is then blown into the molten metal. This stream is first passed through a wash-bottle, through which, as it bubbles up, one can judge the rate at which it is passing through the metal. The first result of the passage of the air is a brilliant white flame, probably due to a mixture of arsenic, antimony and zinc. The violence of the reaction may be checked by moderating the flow of the air. In about an hour the slag has become quite liquid, all excess of silica having disappeared. The stream of gas is then stopped and the charge poured at the end of 20 min., the total time having been three hours. The slag should be liquid, brown in color, and the crucible not corroded. The slag is poured with the metal and adheres firmly to it. A good part may be broken off, and the residual metal is then re-melted and quenched as rapidly as possible, when the slag can be taken off by hammering. In place of adding the fluxes all at once at the beginning of the blowing, they may be added in three or four portions, so as to take up the base-metal oxides as they form.

Composition of the slag: Borax alone is unmanageable, the mixture of borates attacking the crucible vigorously; sand accordingly was used. By a series of experiments it was found that a slag having a composition, $2\text{Na}_2\text{O}$, 9RO , $4\text{B}_2\text{O}_3$, 9SiO_2 was satisfactory. In this formula $\text{R}=\text{Ca}$, Mg , Pb , Zn , Cu , Sb , 0.67 Fe and 0.67 Ni , and it corresponds to the proportion of 3 parts of borax-glass to 4 of sand. For each equivalent of silica we have one of base. It has been found that the zinc is volatilized, so that its percentage in the remaining metal is about 10%. Taking precipitate No. II for example, and dividing each percentage by the atomic weight of metal, we find

$$\begin{array}{cccccc} 7.5\% \text{ Zn} & 20.8\% \text{ Pb} & 2.5\% \text{ Cu} & 12.6\% \text{ SiO}_2 & 0.8\% \text{ SiO}_2 \\ \hline 65 & 205 & 63 & 60 & 60 \end{array}$$

which indicates that in 100 oz. of the precipitate we need barely one pound of sand with, however, three-fourths $(12.6+0.8)=10\text{ lb. borax glass.}$

In precipitate No. V the 10% zinc remaining, just before blowing the air, is approximately

$$\frac{100\%-(39.1\%-10\%)}{10} = 7.1\%$$

so that calculating as before

$$\begin{array}{cccccc} 7.1\% \text{ Zn} & 14.7\% \text{ Ca} & 6.0\% \text{ SiO}_2 & 22.6\% \text{ SiO}_2 \\ \hline 65 & 40 & 60 & 60 \end{array}$$

Thus, in 100 oz., we would need to add 23 lb. sand and 0.75 of the total of $28.6\% \text{ SiO}_2$, or 21 lb. borax glass.

Dr. Rose carried out a series of experiments using oxygen gas instead of air. He found, as might be expected, that the reactions were quicker but more violent, and the clay tube was attacked. The toughening of the purer gold bars was carried out in the same way as above outlined, except that the preliminary distillation was omitted, and the clay pipe introduced into the metal as soon as it had been melted.

Action of oxygen on mixtures of molten metals: Generally speaking the base-metals are oxidized successively with the evolution of heat as follows:

	Calories per molecule.	Calories per lb. of metal.	Atomic vol.
Zinc oxidized to ZnO	82,700	1,270	9.1
Iron oxidized to Fe_2O_3	198,400	1,780	7.2
Lead oxidized to PbO	50,300	240	18.1
Nickel oxidized to Ni_2O_3	120,300	1,020	6.7
Copper oxidized to Cu_2O	37,200	290	7.2

The order of oxidation of other elements is less certain; they are:

	Calories per molecule.	Calories lb.	Atomic vol.
Antimony oxidized to Sb ₂ O ₃	165,900	1,380	17.9
Arsenic oxidized to As ₂ O ₃	154,800	1,030	13.2
Carbon oxidized to CO ₂	97,000	8,080	
Bismuth oxidized to Bi ₂ O ₃	138,000	660	21.1
Tellurium oxidized to TeO ₂	77,200	600	20.2
Sulphur oxidized to SO ₂	71,000	2,220	

In the first list copper containing a little Cu₂O (and the last on the list) acts as a carrier of oxygen to small quantities of more oxidizable metals, hence, when present, it considerably shortens the operation of toughening. Thus standard gold, containing 8.33% copper, was toughened by a short blow, while pure gold was more troublesome. The atomic volume of gold is 10.2 and it will be noticed that the metals whose atomic volume is very different from it, as lead, antimony, arsenic, bismuth and tellurium, embrittle it, while copper, of lower atomic volume (7.2) does not lessen its toughness. All metals during the blowing are to some extent oxidized simultaneously, and here mass action plays its part, but a mixture of metals can be roughly separated from one another by successive oxidation, each metal in turn partially protecting the next in order, while the latter acts as an oxygen carrier for the former. Thus zinc, which goes first, serves to protect the iron from oxidation until itself removed, while the iron, during this time protected from oxidation, is passing on any oxygen it may have taken up to the zinc. The elimination of the last traces of all impurities from gold is not practicable, so

that some copper (or silver) should be present in the charge if tough gold is required, in order to insure the expulsion of deleterious elements. Silver itself, when refined, remains brittle in the absence of copper, owing to the retention of oxygen, which can, however, be removed by melting under charcoal. The oxides of bismuth and lead are mainly volatilized, or are taken up into the substance of the crucible. Part of them, however, remain dissolved in the oxide of copper, so that the effect of blowing is analogous to the poling of copper. In over-poled copper traces of impurities, such as lead or antimony, are reduced to the state of metals and make the copper brittle. Their oxides are innocuous in presence of copper oxide. It has been found that, if a cover of borax be added, the oxides of the deleterious elements are taken up by the slag.

An Ingenious Stamp-Mill.

Written for the MINING AND SCIENTIFIC PRESS
By LOUIS FOGLE and REGINALD LEONARD.

The subject of this article is a steam stamp-mill built to duplicate in a small way the results of large-scale work in milling and amalgamation.

The Mining Department of the University of Idaho possessed a 'baby' Ingersoll drill, the power for which was obtained from the boilers of the heating plant. It was proposed to make a mortar duplicating a large stamp-mill in having a movable die and the same feeding

and screening arrangements, and to use the drilling machine for lifting and dropping the shoe. The patterns for the mortar, shoe, and die were turned on the lathes of the school. The castings were made by a Spokane foundry and weighed as follows: Mortar 180 lb., die 12 lb., and shoe 9 lb. The mortar is ½ in. thick at the top, increasing to 1½ in. on a level with the die. A flange 2 in. wide serves to secure the mortar to the foundation; this is built up of four 8 by 8-in. timbers bolted together and set two feet in the ground; a 6 by 6-in. post, bolted to the side of the foundation and extending some distance above it, supports the machine. The mortar was fastened to the block by three lag-screws. This was sufficient to hold it securely and there was practically no jar noticeable on touching the foundation when the machine was running. The shoe is carried by a

An Ingenious Stamp-Mill.

½-in. steel rod having a taper end fitting the hole in the top of the shoe, the bar being held in the chuck of the drilling machine. The machine was found to work best with a stroke of 4 in., the number being about 200 per min. with 80-lb. boiler-pressure. The ore is fed to the mortar by means of a shaking trough to which a backward and forward motion is imparted by means of a lever operated by the chuck of the machine. The amount of motion is controlled by means of stops and a weight. The feed-opening was designed to throw the ore on top of the die, and was made of larger area at the bottom to prevent choking. The screen-opening on the opposite side is a rectangle 5 by 9 in.; this has proved a little too small. A wooden screen-frame is used and the depth of discharge is varied by means of chuck-blocks. The pulp flows from the lip onto

an amalgamated copper plate 2 by 4 ft., which is supported by a solidly built table having adjustable legs for varying the slope. The pulp is caught in a vat and kept for further treatment.

The first lot of ore run through the mill was a low-grade, extremely hard white quartz containing less than one per cent galena, blende and pyrite. It was first run through a small Dodge crusher to pass a one-inch ring, weighed, sampled and assayed. The lot was then taken to the bin of the mill and the stamp started. The run was made with the idea of determining the consumption of water, the capacity of the mill, and its efficiency as an amalgamator. The determination of capacity was not successful, owing to over-feeding, due to improper working of the automatic feeder. The second lot of ore tried was a high-grade quartz which had been previously crushed to pass a 5 mm. screen. The fineness of the material hindered, rather than helped, the crushing in the mortar. The third trial was made on another lot similar to that of the first run. The feeder having been adjusted, this test demonstrated the capacity of the stamp better than either of the others. To help amalgamation and insure the removal of all the gold caught, a coating of silver amalgam was used on the plates. No mercury was fed with the ore, but on cleaning out the mortar after the second run, a large amount of free gold was found. This was amalgamated in a gold pan, silver amalgam being added to guard against loss in the subsequent retorting and melting. The results are given in the following tables :

TABLE I. DETAILS OF RUNS.

Run number.	Weight of ore.	Assay value.	Gold in lot.	Time.		Water per ton.	Crushed per day.	Assay tailing.	Value bullion.	Extraction-%.	Actual %.
				hr.	min.	gal.	lb.				
1	535	\$2.48	\$0.66	9	42	938	1,360	\$1.24	\$0.264	50	40
2	156	44.65*	3.48	2	7	938	1,780	6.71	2.96		85
3	160	2.48		1	30	938	2,570	1.14		54	

*Assays of this ore (Lot 2) varied a great deal on account of coarse free gold, and the value was arrived at by taking the sum of bullion recovered and the assay of the tailing. The extraction by assay and the actual recovery are therefore the same.

TABLE II. DETAILS OF BULLION.

RUN NUMBER.	Weight of bar—(grams).	Fineness, parts per 1,000.	Amount of gold in bar—(grams).	Value of gold.
1	33.24	12	0.399	\$0.264
2 (on plates)	17.99	58	1.04	0.67
3 (inside mortar)	16.595	209	3.47	2.29
Lot 2, total gold			4.51	2.96

The efficiency of the mill as an amalgamator seems to be high, and furnishes a means of testing small lots by amalgamation. The extraction of 50% from the first lot was satisfactory, especially since it had been claimed that the ore could not be amalgamated. Ore from the same mine had been previously run through a stamp-mill and no recovery made. The reason offered was the presence of arsenic (?) in the ore. A sizing test was made on the pulp with the result shown in Table III. A 40-mesh woven-wire screen was used on the mortar.

TABLE III. SCREEN TESTS.

Through 40 caught on 60	32 %
Through 60 caught on 80	10 "
Through 80 caught on 100	7 "
Through 100 caught on 120	17.5 %
Through 120 caught on 150	8.5 %

The results shown above indicate a pulp of about the same sort as is produced in ordinary stamp-milling.

How Nuggets May Be Made.

Written for the MINING AND SCIENTIFIC PRESS
By CHARLES S. PALMER.

Nuggets of copper, silver, or gold are common enough to deserve a word regarding their origin. The probable chemical state of copper and silver in their original ores, was that of the sulphide; this is shown by the general relations of the outer oxidized crust of the globe (where oxygen reigns supreme as the active agent of change), and the next deeper layer, where sulphur combines with the metals to make the original ores. Of course, in these remarks, the word 'original' is used almost apologetically; for what can we, the creatures of a day and the dwellers in a valley, what can we really know of anything original? We may use the word as meaning the farthest back that we can trace the substance in question. For we know that while we can never prove it absolutely, yet all the inferences from well-known facts indicate that the earth has a centre, which, as compared with the exterior, is heavy, unoxidized and metallic.

To anyone studying the problem of nuggets, it is obvious that the gradual oxidation of a sulphide, such as of copper, would result in the production of a metallic residue; because the principal sulphide copper glance is a cuprous sulphide, in which there are two atoms of copper to one of sulphur; and the only really soluble sulphate of copper is common blue vitriol, cupric sulphate, which has one atom of copper to one of sulphur. Hence, when the cuprous sulphide ore is oxidized, all of the sulphur could go off with one-half of the copper in the form of soluble cupric sulphate; and another half of the copper could remain behind as metallic copper.

In the case of iron, the common original ore would seem to be the ubiquitous pyrite; this is a super-sulphide, in the sense that for one atom of iron, there are two atoms of sulphur; hence, when this substance is oxidized, if the iron goes only to the ferrous sulphate, there is more than enough sulphur to make the sulphuric acid necessary to carry off the iron as soluble sulphate; while if the iron goes to the form of ferric sulphate (which is soluble), even then there is more than enough sulphur to carry the iron. This fact may be one of the explanations of the remarkable fact that native iron is very much more rare than it should be on the crust of the earth, even considering its readiness to oxidize. And this rarity of native iron, in proportion to the abundance of such ores as pyrite and marcasite, is entirely in keeping with this excess of sulphur in pyrite and marcasite which have more than enough sulphur to take care of the iron as it is changed into the soluble form of sulphate.

The case of silver is equally instructive. The common original ore is silver glance, or the sulphide, with two atoms of silver for one atom of copper. These proportions are the same (as far as the silver and sulphur are concerned), as the proportions of silver and sulphur in the silver sulphate that would be formed on the oxidation of the silver glance. In plain English, this means that all the silver could be soluble; and, in the simple oxidation considered by itself, there need be no metallic unoxidized residue of native silver (as in the case of the copper). This fact is met by another fact, namely, that from a solution of silver sulphate, metallic silver is easily reduced and thrown down by the weakest reducers (such as certain organic compounds, or ferrous sulphate, or metallic copper); and this is simply sufficient to explain the comparative abundance of native silver.

When we come to gold, we are met by the fact that, argue as we will, we have no sharp proof of the non-existence of gold sulphides in nature; and they are well known in the laboratory. If such could exist, by the oxidation

of the mixed sulphides in which gold usually exists, a solution could be made from which the gold would be reduced by the ferrous sulphate, or by the metallic copper; and if copper and silver were together, by the silver reduced from the copper. But in the total absence of certain knowledge on this point of the condition of the gold, and assuming that it is usually in the form of metal disseminated through pyrite, it is clear that all the rest of the ore could oxidize and flow away, leaving the gold in the form of particles more or less agglomerated.

It is evident that the theoretical analysis of the question of the production of metallic copper, silver, gold, and iron, by the oxidation of their respective sulphides, is well in keeping with the facts as known. By the way, it should be mentioned that some of the double ores of copper and iron, such as chalcopyrite, have enough sulphur to carry off all the iron as ferrous sulphate, and all the copper as cupric sulphate; and the sequence of finding first silver and silver ores in such regions as Butte in the early day, to be succeeded by the finding of copper ores at lower depths, is no accident, but illustrates the same laws that have been touched upon thus far.

Now, on the practical side, I have a set of oxidation products of artificial sulphides that would seem to be almost a complete epitome of the formation of metallic copper from matte. The specimens were found in a riffle in a launder which was used to carry off the waste slag from the large blast furnaces of the Washoe smelter, in Montana. This water is a hard water, but otherwise exhibits no peculiar properties, except its heated condition due to the cooling of the molten slag which falls into the launder in a constant stream. The launder slopes so that the current is rapid enough to carry off blocks many times larger than the powdered slag, which will average from the size of a cherry down to fine shot. This rapidity of the water gives the current force enough to roll and pound any lumps, coarse or fine; and the riffle would make an ideal artificial 'pot-hole' wherein the rolling and rotating pieces of matte could oxidize, and, at the same time, hammer themselves to a coherent mass.

The specimens of matte are sufficiently complete to enable one to trace almost every stage, from the first in which the change has only well begun, to the last where the shape of the original matte is lost, and the metallic copper is clearly of the nugget type, with the characteristic 'thumb-marks,' and potato-shape. The lines of blow-holes of the original matte are well preserved in some cases, the analysis showed the concentration of gold and silver along with the copper. The series and the changes are quite complete.

To test the observation of the apparent formation of nuggets from matte, I took a series from the common low-grade 40% copper to high-grade white metal. These were placed on a stove in a common casserole and kept covered with water, which was poured off once or twice every day. The stove on which the casserole was placed was kept hot only a small part of the time each day; but even with this rough imitation of the slag launder, the incipient change which took place in five or six weeks was striking. The high-grade matte began to oxidize most, the rusty portions showing much copper when burnished with a knife point. It should be mentioned that these specimens of matte were selected for experiment which showed little included free copper.

With the matte, several pieces of copper glance were tested. These began to oxidize, but not nearly so much as the matte; but all clearly started on the road to the copper nugget condition. Judging from the amount of change effected, it would require at least a year to oxidize an inch lump of matte to good nugget form; and there is one feature of the launder which cannot be imitated on a kitchen stove, namely, the rolling, tumbling, and pound-

ing of the metal to make it more coherent. That the general method of alteration to nuggets is imitated herein, there can be little doubt, at least in certain phases.

The lumps of matte in the riffles of the slag-water launder were undoubtedly stray drops from the pots that stand near the launder; and it was their heavy specific gravity that put them in the riffles and kept them there. It was a fortunate observation that brought them to light, for they are one more link in the chain which gradually shapes theory into fact; the specimens were given to me by an old observer who sees and finds everything.

There is said to be nothing great and nothing small in the world—in the sense that the great and the small are intimately and mutually connected with each other and with the same causes and results. This suggests that the making of a small nugget may be closely connected with the making of a big one; and the same process herein described may be related to that which placed such enormous deposits as those of the Lake Superior region. Certain it is that the longer men study nature, the more do they incline to explain all changes by the common ordinary agents that can be seen at work in daily activity about them. It may be only a step, and that a small one, from the nugget of the launder of the copper smelter, to the copper mass in a Calumet & Hecla mine.

BARYTES.—This is the common name in the United States, where it would be an affectation of simplicity to name it, as in England, 'heavy spar.' The pure mineral (barite) BaSO_4 has a specific gravity of 4.5, and so is much the same in density as the white lead with which it is mixed as an adulterant. For such purposes it is largely mined in Virginia and Missouri, small amounts only coming from North Carolina, Illinois, and other States. It is found in nodules and boulders of float mineral imbedded in clay, as also in regular beds. It is prepared by picking and washing for subsequent grinding, and should be free from metallic impurities which discolor it, and from quartz grains. It is coarsely crushed, then wet-ground under granite stones. Next it is treated with dilute sulphuric acid for the purpose of removing the iron oxide; the solution is then drained from the vat and the mineral washed with water until freed from the acid and dried. It is one of the most important and durable of pigments, coming in importance next after white lead, and is insoluble both in acids and alkalies. As an adulterant it can be employed to the extent of 35 to 50 per cent. The best grades range in value from \$15 to \$20 per ton, and the raw mineral is worth \$6 per ton in St. Louis.

MACHINE AND HAND-DRILLING.—The rate at which a tunnel can be driven by means of rock-drills may be safely taken at double the speed of hand-work. Thus, in driving the Vosburg tunnel (8 by 20 ft.) on the Lehigh Valley railroad, through a uniform hard gray sandstone, by hand-drilling, the progress was 67 ft., while by machine-drilling it was 173 ft. monthly. For driving or for sinking, rock-drills are far superior to hand-labor, both in speed and in economy. For stoping, however, except in wide stopes, the differences are not so marked, as it is difficult to maneuver a machine in places where a man can hardly find room to work with a single-hand hammer. The great advantage in the use of rock-drills is undoubtedly the increased speed with which a mine can be developed and ore reserves created, since, for cost per yard, there is not much difference between either that or hand-drilling. The point is a little difficult to decide, but it would be safe to say that the average cost per yard by either system is the same for ordinary mine drifts, while, for full-sized tunnels, machine-drilling is cheaper.

Examples of Faulting.

In a recent issue of *The Queensland Government Mining Journal* we find several interesting examples of faulting in the Golden Gate mine at Croydon, Queensland. We have re-drawn six of the diagrams, correcting obvious errors in Fig. 5 and 6. Of the first group, Fig. 1 shows the Golden Gate Reef broken by a dike and subsequently faulted by a movement along the lower wall of the vein, dislocating the dike. The same vein and dike are shown in Fig. 2, where the western part of the vein is faulted along the hanging wall of the dike from *c* to *d*. Finally,

and drifts would be multiplied in the effort to ascertain the position of the ore. Dirgrams such as these are useful in suggesting an explanation of occurrences underground, for it is not often that a mine manager is keen enough on structural geology to unravel such a complicated tangle off-hand. A good example of a multiplicity of faults in a single mine was afforded by the Enterprise at Rico, as described in Vol. XXVI of the *Transactions* of the American Institute of Mining Engineers. These series of four or five veins were faulted on an average every sixty feet, so that the superintendent and manager had to face a fault at least once every week. As a mat-

FIG. 1

FIG. 4

FIG. 2

FIG. 5

FIG. 3

FIG. 6

Two Examples of Complicated Faulting.

In Fig. 3 the vein and the dike and the later fault-plane are all thrown to the east along a thrust-plane *g h*, breaking the dike at *e f*.

In the next series, reversed faulting along two planes is illustrated. Fig. 5 shows the quartz vein cut by a dike, which is subsequently crossed by a fault *a a*. This is a normal fault as indicated by Fig. 2, where the upper half of the dike at *A* is lowered below *B* and the vein is separated by an equal displacement. Finally, in Fig. 3, we get a complication of movements due to two thrust-planes along *dd* and *ee*, the result being that the two parts of the dike are shifted again so that two of the original fragments at *A* and *B* are now upside down, and the plane of the first fault is disrupted twice. Such a complication would worry a mine superintendent, whose winzes

ter of experience it was found that one rule worked in almost every instance and the exception was obscure. The rule was that if the drift or stope met the fault on its hanging-wall side, you looked for the broken portion of the vein on the hanging-wall side of the vein, if the drift cut the foot-wall of the fault-fracture, then the other part of the ore vein was to be found on the foot-wall side of that vein.

HARMONIOUS order governing eternally continuous progress—the web and woof of matter and force interweaving by slow degrees, without broken thread, that veil which lies between us and the Infinite—that universe which alone we know or can know; such is the picture which science draws of the world.

A Hot-Blast Stove Efficiency Test.

Written for the MINING AND SCIENTIFIC PRESS
By HERBERT HAAS.

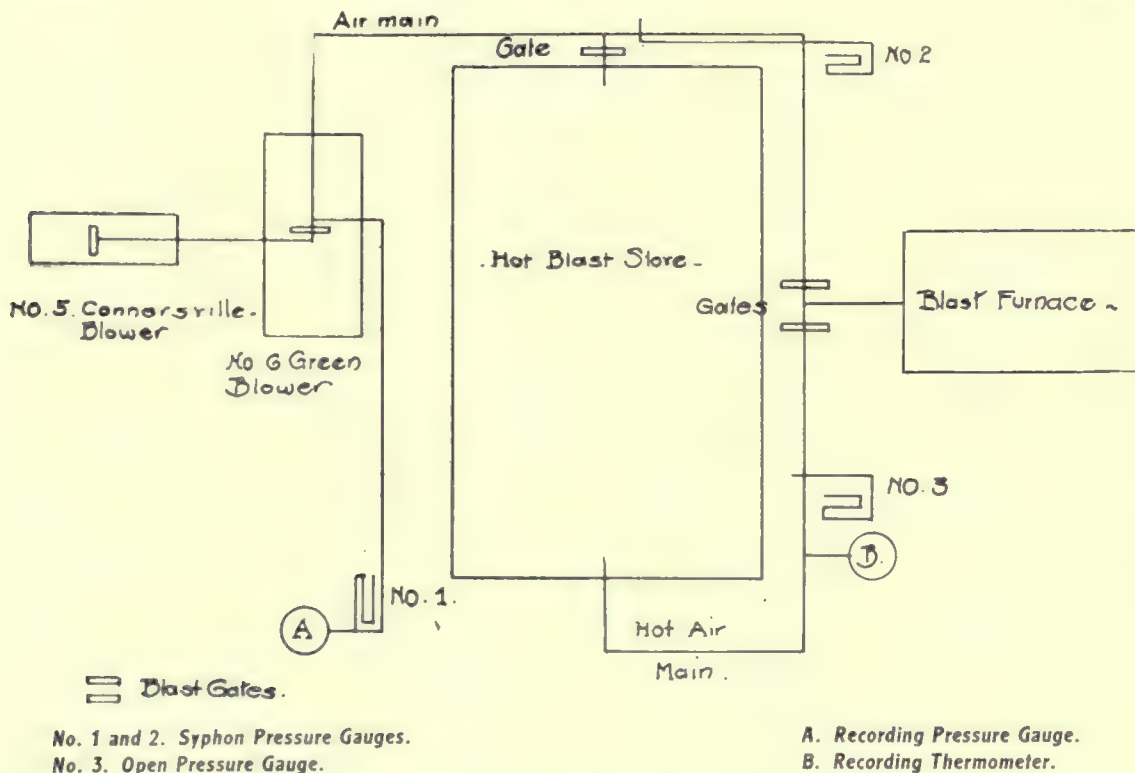

The use of heated air in pyrite smelting gives renewed interest to the U type of stove. Such stoves are now but little used in iron metallurgy, having been displaced by the more efficient regenerative hot-blast fire-brick stoves of the Whitwell & Cowper type. Unfortunately, these old U-pipe stoves were adopted without alterations to meet the radically different conditions in pyrite smelting, where the ratio of air-volume to pressure is greatly different from that common in iron blast-furnace work.

It is therefore not surprising that the copper metallurgist condemns the hot-blast stove as an extremely wasteful apparatus. Mr. Lang, for instance, places the thermal efficiency of the common U-pipe stove at 50%, and the frictional losses at from 6 to 16 oz. over the pressure

ments. All of these were manufactured by the Schaeffer & Budenberg Mfg. Co., New York. In the blower room a Metropolitan recording pressure gauge was used for registering the variations in air-pressure during one day's operations. It is indicated at A. A syphon pressure-gauge was installed alongside, for purposes of comparison (1).

No. 2 and 3 are syphon and open pressure-gauges; No. 1 and 2 had a range of 5 lb. each, with subdivisions of 1 oz. pressure per sq. in. These gauges were tested occasionally against columns of water, affording better opportunity for observing slight changes of pressure.

B is a combined recording and indicating mercury pyrometer, with temperatures from 100° to 1,100° F. As will be seen from the diagram, pressure determinations were made at three points, to wit: At the blowers; at the hot-blast stove-inlet; and at the outlet. The average air-pressures were 24 oz. per sq. in. recorded at the

registered at the blower. In the report of the Secretary of Mines, Tasmania, treating at length on smelting at Mt. Lyell, it is stated that the blast-pressure ranged from 36 to 40 oz. at the blowers, and from 30 to 34 oz. at the furnaces, the difference at the two points being lost by friction in hot-blast stoves, blast-mains and furnace-connections. In other words, from 15 to 17% of the pressure recorded at the blowers is lost in the manner stated.

I designed a hot-blast stove, a description of which appeared in *The Engineering and Mining Journal*, December 29, 1904, to meet the radically different requirements in pyrite smelting. The stove was built and used in connection with the blast-furnace plant at the Afterthought smelter at Ingot, in Shasta county, California. The following notes describe an efficiency test of this stove:

From careful records, during the months of March to July, 1905, of the average volume of air heated per 24 hours, the average air-pressures at blowers, inlet and outlet of hot-blast stove, and tuyeres, average temperature of inflowing and outflowing air, average temperature of composition of combustion-gases at the stove-flue outlet, the average heat-value and quantity of wood burned, the working conditions of the stove were determined. The accompanying diagram gives the arrangement of the air connections, with the position of the different instru-

blower. The average pressures recorded by gauge No. 3 ranged from 22 to 23 oz. per sq. in. This represents a frictional loss of 4 to 9% of the initial pressure at the blower. The loss between No. 2 and 3 never exceeded 3%; it is interesting to note that the average frictional loss estimated when the stove was designed was 4 per cent.

To determine the thermal efficiency of the stove the recording pyrometer was used.

Average volume of air heated per 24 hr., in cu. ft. per min.	7,500
" temperature of air going into stove	66.2° F. 19.0° C.
" " " out of "	543.2° F. 284.0° C.
" " of combustion gases	392.0° F. 200.0° C.

The wood was delivered through a flume. It was in the form of slabs. Average determinations showed that it contained 40% moisture. As a supply had not been accumulated, the wood had to be used in this condition. Calorific determinations of the wood substance (cellulose) showed a heat-value of 3,800 kg. Cal. = 15,080 B. T. U. The average number of cords used was 8.5, at 2,800 lb. per cord, of which 40% was water.

The heat balance was computed to be as follows: Heat furnished by 8.5 cords wood:

$$2,800 \text{ lb.} \times 60\% = 1,680 \text{ lb.}; 1,680 \text{ lb.} \times 0.4536 \text{ kg.} \times 8.5 \text{ cords} = 6,177 \text{ kilograms.}$$

$$6,477 \text{ kg.} \times 3,800 \text{ kg. Cal.} = 24,614,120 \text{ kg. Calories.}$$

Heat used—Air: 7,500 cu. ft. \times 0.028317 cbm.=212.4 cbm. minutes.

212.4 cbm. min. \times 0.2375 (284°-19° C.) \times 1,440 min. = 12,247,904 kg. Calories.

Water in wood: 2,800 lb. \times 40% \times 8.5 cords = 9,520 lb.; 9,520 lb. \times 0.4536 = 4,318.3 kg. H₂O. Regnault's formula: W = heat units (kg. Cal.) required for rising 1 kg. water at t° C. to saturated steam at T° C. 606.5-305 (T°-t° C.)=606.5-305 (200°-19° C.) \times 4,318.3 = 661.7 \times 4,318.3=2,857,419 kg. Calories.

Combustion gases at 200° C., computed from analysis of gases and wood substances (cellulose) which contained 44.4% carbon, 49.4% oxygen, 6.2% hydrogen.

24,614 kg. nitrogen \times 9.2438 \times 200° C. = 1,200,178 kg. Calories.

3,451 kg. carbon dioxide \times 0.2169 \times 200° C. =149,704 kg. Calories.

3,200 kg. water \times 0.475 \times 200° C. = 304,000 kg. Calories.

Nitrogen.....	Kg. Cal.
Carbon dioxide.....	1,200,178
Water.....	149,704
.....	304,000
Total.....	1,653,882

Excess of air supplied to fire-box carried away 618,500 kg. Cal.

Air.....	19,217,904 kg. Cal.	78.2% of A.
Water.....	2,857,419 "	11.6 " "
Combustion gases.....	1,653,882 "	6.7 " "
Excess of air.....	618,500 "	2.5 " "
Radiation, etc., to balance.....	236,415 "	1.0 " "

24,614,120 kg. Cal. = A = 24,614,120 kg. Cal. = 100.0% of A.

According to the above results, 78.2% of the heat-value of the wood was transmitted to the blast-furnace in the form of heated air. This is the absolute efficiency. It is low, because of the excess of water in the wood.

With coal or oil fuel, the absolute efficiency would probably exceed 85%. The 19,247,904 kg. Cal. would equal 2,406 kg. coke with a calorific value of 8,000 kg. Cal. or 2.65 tons (at 2,000 lb.). The price of coke delivered at the smelter was \$21 per ton, or for 2.65 tons, \$55.65. The operation of the hot-blast stove cost \$38 per 24 hr. This leaves, in favor of hot blast, \$17.65.

In the price of coke, weighing and charging are not included. The cost of heating the blast, with hot-blast stove maintenance, was 25c. per ton of charge smelted. The cost of using coke in the blast furnace and figuring on a thermal efficiency of 100% would have amounted to 37c. per ton.

The amount of \$17.65 only measures the commercial gain in using heated air instead of coke. It must also be remembered that the thermal efficiency of shaft furnaces (where material to be heated and fuel to be burned are in direct contact) is from 30 to 50% only; the air would be used with a greater thermal efficiency than coke with the same number of heat-units, so that \$17.65 does not represent the entire gain; that is, the higher temperature obtained at the tuyeres by the use of heated air, with accompanying higher re-action powers between iron monoxide and silica means a more rapid oxidation of the iron sulphide.

COMPRESSED AIR can be conveyed in pipes for several miles and still be capable of performing useful, if not economical work. For the transmission of power, whether to rock-drills, pumps or hoists, it has the serious defect that heat is accumulated during its compression. The piston of the compressor must meet, not only the natural resistance of the air, but, in addition, that due to expansion arising from the heat of compression. Taking a cubic foot of air at 0° F., let us compress it to 58.8 lb. per sq. in.; the volume of air will be reduced to 0.3194 cu. ft. and its temperature will have risen to 309.4° F. The absolute need of taking in air to the compressors at as low a temperature as possible, and of cooling the compressing cylinder by the circulation of a constant stream of jacket-water, is evident from the above example.

Waste in Mining.

By SIDNEY J. JENNINGS.

*When men began to analyze the process of mining minerals from the earth, the great cost of preparing the excavations necessary for the purpose probably first impressed them. Some means were sought by which this cost could be reduced. Very soon there probably arose some man with the suggestion to do away with the excavations altogether, his argument probably being that the only necessity for large excavations was to enable men to get to the places where the ore was; that it would be much simpler to get some solvent that would selectively dissolve the desired material from the surrounding waste, and the enriched solution could be pumped to the surface, and there treated so as to separate the solvent from the dissolved commodity sought for. This idea proves wonderfully attractive to some men—all the more so because in certain cases it has been successful. Many salt mines are worked on this principle, and some copper mines under very special circumstances have used this idea, the solvent in these cases being water. I have also heard of one silver mine worked on this scheme, the solvent being hyposulphite of soda. Since the discovery of the solvent action of cyanide of potassium on gold, it was to be expected by anyone possessing any knowledge of human nature that the idea of treating gold ores *in situ* by cyanide of potassium would be suggested. But I must confess that I have been surprised by the number of times this idea has been brought before me and the different classes of men who have suggested it. The care and thought devoted to the perfection of the details of the schemes have been very great, while their essential difficulties have been forgotten in the enthusiasm fired by what their inventors conceived to be a new and great idea. While I am the last who would defend an idea merely because it is old, or who would seek to prevent the enquiry by new minds into old and apparently well-established practice, I think that you will agree with me in including all the energy expended on the above outlined idea in the category of wasted thought.

Situated as most metalliferous mines are, far away from stir of cities and the crowding of men, the administration of a mine tends to become that of a one man show. This undoubtedly accentuates the individuality of the manager, makes him self-reliant and resourceful, but it also tends by that very accentuation of individuality to make him insist on doing things in his own way, without sufficient consideration whether that way is the best one possible. The very resourcefulness of a mine manager induces him to try all sorts of experiments which others have tried and tried again, and whose futility have been thoroughly demonstrated. These defects of the virtues of a mine manager are not so prominent when there is only one mine in a camp, but when, as in Johannesburg, you have over sixty producing mines, the subtle friction of mind upon mind produces all unconsciously to the individual an excitation which is apt to result in a series of experiments, the vast majority of which will have been tried before, and the resulting waste of thought will be great. Some years ago a mine manager boasted to me that he had never been over any other mine on the Rand except his own. His plant showed evidence of this. Some things were excellent, but many designs showed evidences of great ingenuity in doing things in a roundabout way—the same effect being accomplished on neighboring properties in a much simpler fashion.

One of the means adopted on the Rand to obviate this waste of thought has been the grouping of several mines

*An address delivered before the South African Association for the advancement of science at Kimberley. Abstracted from *South African Mines*.

under one central administration. While undoubtedly centralization when pushed to an extreme can have a deleterious effect in crushing out initiative and reducing the sense of responsibility of the manager, it has had, and when wisely administered will continue to have, a most beneficial effect in making the results of one experiment in any given direction, whether positive or negative, immediately available to all the members of the group, by aiding the manager in all his difficulties with the advice of another experienced and matured mind, thus substituting the deliberate judgment of two men for the possible rash acts of one. Centralization also allows the results achieved in any one department of a mine to be compared on a uniform basis with the results achieved in the same department on any other mine of the same group. Thus while centralization saves the waste of thought in experimenting and resolving problems already adequately disposed of, it promotes thought in showing what other men have achieved in the same line, for nothing gives cause for such quick and steady thinking as a comparison on a uniform basis which shows your own work in an unfavorable light. Centralized management has also other advantages which do not come within the range of our present consideration, and which, therefore, I will not deal with now. Undoubtedly it can be pushed to such an extreme that its evils outweigh its advantages. But these prejudicial effects are not inherent in the idea of centralization; they are mere excrescences which have been allowed to grow on the system, whereas the good that can be achieved by the system is an integral part of the idea on which it is founded. These inherent advantages give the centralized system a vitality by means of which it must survive any surgical operation, however heroic it may be, necessary to cut away its abuses.

Here in South Africa, where the division between laborer and overseer is so sharply accentuated by the color line, where the Kaffir forms such an exceptionally powerful muscular machine, and at the same time is supposed to be so relatively cheap, the temptation to waste labor is tremendous, and is, I am afraid, not always successfully combatted. Not only does this waste of labor comprise the relatively cheap Kaffir, but extends to the much more highly paid overseer; for if laborers are employed in too great numbers on any given piece of work, the cost of supervision must in proportion be unduly inflated. Viewed as a source of human energy, the Kaffir stands high in the scale of laboring people, but from the facts that relative to his wants his remuneration is enormous, and that his sense of responsibility is very inadequately aroused, it is difficult to train him to be as efficient a workman as he is seemingly capable of becoming.

As far as the routine surface work on the mines of the Witwatersrand is concerned, their managers claim, and I think with justice, that the waste of labor has been reduced enormously since the opening of these fields, and that the margin for further reduction in this direction is very small. As an example of what has been done, I would instance the fact that the number of employees in a certain 100-stamp mill with crushers, in the year 1890, was 28 white men and 121 natives; this mill crushed under 5,000 tons a month. At the present time a 100-stamp mill, crushing 14,000 tons of ore a month, will only employ 11 white men and 27 natives—showing that the labor, measured by the tons crushed, has been made eleven times as effective. I have seen, as doubtless many of you have also seen, Kaffirs who looked on a shovel for the first time, and whose conception of its use was limited to placing it on the ground, carefully filling it with ground scooped up in his hands, triumphantly placing it on the top of his head, then bearing it off to the spot to which the ground had to be shifted. And I have also seen Kaffirs who were able in a day to load 40 tons

of sand into trucks, and shift them 40 feet, a task which would be considered excellent work anywhere in the world. If the labor force of any industrial venture is largely composed of men like the first mentioned, a huge waste of labor will for a time be the result, whereas if any large proportion can accomplish similar work to that of the second set of workers, then the manager of such an enterprise can view an inspection of his labor sheets with equanimity and unconcern.

While undoubtedly an enormous amount has been accomplished in reducing the waste of labor on the mines of the Witwatersrand, we still have to acknowledge that enough remains to be done to engage the serious attention of those who have the interest of these mines at heart. Personally I am no great believer in what has been called 'dramatic economy of labor.' Under such an impulse, the interest on the capital necessary to be spent in order to save the labor of one man, is apt to exceed the wages which would have to be paid that man. I am, however, a great believer in the slow, laborious, but permanent effect of education on the laborer. Catch the Kaffir young, educate him so that he knows how to work, instil in him sufficient ambition and enough wants to make it necessary for him to work continuously in order to satisfy them, then that very necessity for continuous labor will draw out and increase his sense of responsibility so that he can be trusted to do his work properly without the excessive and wasteful supervision now necessary. Also educate the overseer to realize that he is a foreman of a gang of laborers whom he has to train to work to the best advantage, and, this accomplished, you will have probably reduced the wastage of labor to the minimum possible under South African conditions.

In considering the third kind of waste in mining, that of material, the subject divides itself naturally into two sub-heads:

1. The waste of the mineral sought for.
2. The waste of minerals used in the process of acquiring the mineral.

On the Witwatersrand enormous strides have been made in reducing the first-named waste. In 1891, on one of the better managed companies of these fields, a close inspection of the gold returns showed that only 57% of the assay value of the ore was recovered. In other words, for every sovereign's worth of gold contained in the ore treated only 11s. 5d. worth were recovered; whereas under the latest metallurgical practice on these fields by the use of tube-mills 95% of the assay value of the ore has been banked. This means that out of every sovereign's worth of gold contained in the ore treated, 19s. were put into the bank. Of course the difference between 11s. 5d. and 20s. was not all lost. A large portion of this difference was contained in the tailing which was stored and treated in subsequent years. None the less an immense advance in metallurgical practice has been made; so great indeed has this advance been that on the best equipped mines little remains to be done in the direction of reducing waste of the commodity sought for. The ingenuity of the engineer is exercised in bringing older plants into line with the newest practice at the least cost for capital expenditure.

The waste of stores used on the gold mines of the Transvaal has been great in the past, and continues at an excessive figure. This is a case where the directing brain is practically at the mercy of the performing hands. Large reductions have been made in the cost of coal, explosives, cyanide and candles, which form the four largest items of expenditure of the gold mines. In the case of coal this reduction has been achieved by decreasing the railway rates, and also by a slight reduction in the price at the pit's mouth. The cost of dynamite has

been reduced nearly one half through the freeing of the country from the grip of the former monopoly. Through improvements in manufacture and by the competition of manufacturers, the cost of both cyanide and candles per unit consumed has been greatly reduced. As far as coal and cyanide are concerned a close supervision of their consumption has taken place, and continues to occupy much of the energies of the engineering and metallurgical talent in the Witwatersrand. I estimate that if all the plants could be run with as small a consumption of coal per ton of ore crushed as the most economical plant uses, then the consumption of coal would be reduced by about one third of the present amount. While it is out of the question, owing to the heterogeneous design of many of the plants, to expect any such saving to be made, a great improvement can still take place, and undoubtedly will gradually be brought about.

The directors of the mining industry have made a long, determined, and serious effort to diminish the waste of explosives, candles, and other stores used underground, by paying the men by the results obtained. Some improvement has taken place, but to many observers it seems that an even greater improvement would ensue provided the intelligent and loyal co-operation of all the men were continuously secured.

Tin in the United States.

The United States Geological Survey has published a report on the present status of tin mining :

During the year 1905 there was no actual production of metallic tin in the United States, the only ore production being an insignificant quantity from the placers of Buck creek, Alaska. There was no output from the lode claims of the York region, Alaska; none from South Carolina, although 38 tons had been washed from the residual placers at Gaffney, in the northern part of that State, in 1904; nor was any production reported from the Black Hills region of South Dakota and Wyoming.

In Alaska the season was exceedingly bad, so that sluicing on Buck creek was carried on with great difficulty, and this, together with other reasons, resulted in a small showing for the year's work. However, the first really good prospects on Cape Prince of Wales were found during the year, and the possibility of future production is not without hope. There was prospecting in the Lost River valley of the York region, where larger quantities of tin ore were shown to be present than had been known, and small veins were found at several points in the vicinity of the original discovery. Small veins of cassiterite-bearing quartz were found in the slates around the head of Buck creek, and small stringers of cassiterite were also found in granitic intrusions. These, however, hold no great promise as to future production. From Ears mountain, 40 miles east of Cape Prince of Wales, specimens of supposed tin-bearing rock have been brought by a number of parties; but although tin ore has undoubtedly been found there, the minerals taken for cassiterite are, more often than otherwise, either tourmaline or augite. What the extent of the deposits may be is wholly unknown. Some stream tin has been found in the creeks heading on the mountain.

Prospecting for stream tin has been carried on, and has shown cassiterite to exist in variable quantities in many of the small streams flowing into Lopp's Lagoon, but in most of these streams it would be difficult to get sufficient water for sluicing. Good prospects are reported as being found in Grouse creek, below the mouth of Buck creek. Small quantities of stream tin have been found in a number of other creeks of Seward Peninsula, but nothing so far shown warrants the statement heralded in glowing

prospectuses that there is "tin enough in sight to supply the world."

In the Black Hills some prospecting was carried on in both South Dakota and Wyoming, and a small experimental mill was erected at Etta mine. It is hoped that there will be some output during the present year.*

In the South Carolina-North Carolina region, although there was no output, much prospecting and development work has been carried on, especially at King's Mountain and Lincolnton. At the former place a mill with rolls, jigs and tables was erected; several shafts were sunk to a depth of 40 to 50 ft., and prospecting is being carried on on the old Ledoux properties south of the town. Some concentrate has been obtained. At the Jones mine, 7½ miles north of the town of King's Mountain, a small roll-mill with two Bartlett tables was erected, and a little concentrate was turned out. Some very promising ore has been struck, and prospecting is being done at the 100-ft. level. About a mile and a half north of Lincolnton, N. C., extensive prospecting has been carried on, a large number of surface trenches have been dug, some hundreds of feet of drifts driven, and rich ore has been uncovered at a number of places. At the Ross mine, about a mile north of Gaffney, S. C., and but a few miles below the North Carolina State line, a hoisting engine and a pump have been installed and a shaft 121 ft. deep has been sunk. Several hundred feet of drifts have been run on the 65 and 95 ft. levels. A number of tons of ore are upon the dump ready for treatment, and a small quantity has been washed in sluice-boxes. The country rock and gangue here is greatly decayed.

At the El Paso, Texas, deposits there have been no notable developments. In California some prospecting is said to have been carried on at the old Temescal mines and near Santa Ana, but there has been no resulting production during the year. No new occurrences of tin are known to have been found in the United States in 1905.

Although complete figures of the output of tin in foreign countries are not at present available, it is possible to give what is believed to be a very close approximation, as follows: Malay States, 65,565 net tons; Bolivia, 13,646 tons; Banka, 11,155 tons; Cornwall, 5,040 tons; Australia, 5,028 tons; Billiton, 2,715 tons; total, 103,149 tons. This total is about the same as that of 1904, which was 103,134 net tons, the difference between the two not being as large as the probable errors in the figures.

MEASURING FLOW OF AN ARTESIAN WELL.—Under conditions where a weir could not be built, a novel way of measuring the flow of an artesian well was devised. Forty feet of 10-in. pipe was screwed into a 90° elbow on the pipe where it came out of the ground, and a hand force-pump attached to a small hole tapped into this pipe. The force-pump drew a red aniline liquid from a pail and injected it into the stream, where it was carried along with the water and at the same rate. By means of a stop-watch and the known carrying capacity of the pipe the flow of the well was easily determined.

CHARLES DARWIN abhorred mere speculation as nature abhors a vacuum. He was as greedy of cases and precedents as any constitutional lawyer, and all the principles he laid down were capable of being brought to the test of observation and experiment.

*There has been more recent activity in the tin-mining industry in the Black Hills than is indicated in the above paragraph, referring to South Dakota and Wyoming. A large concentrating mill was built at the Etta mine in 1885, which was abandoned after a brief run owing to small amount of ore available, but a new experimental plant has recently been built at the Gertie mine, near Hill City. At Tinton in Lawrence county, the Tinton Company has a testing mill which has been operated from time to time, testing the ore from the various mines of the company. In southern California some prospecting was done last year by lessees at the Cajalco mine, of the San Jacinto Estate Co., near Corona.—Editor.

Ramsey, Nevada.

The newest mining town in that land of the fortune hunters, Nevada, is called Ramsey. It lies on the north slope of Alamo mountain, at the head of Morgan cañon and is reached from Churchill by stage, distant 15 miles. It is 25 miles northeast from Virginia City. Already, at least one man has been shot in a dispute over claims, and Ramsey is now a full-fledged camp, growing at a lively rate. It is the result of the discovery of gold by the Ramsey brothers in the neighboring mountain early in the present year. To reward themselves for their dis-

a saloon, the next by newspapers—the miner sometimes coming third in the race.

The new-comer early in the rush sets up his tent and taking his pick and canteen strikes out at daylight into the hills to find the rich mine of which he has dreamed, but he is unusually fortunate if he can find a vacant piece of ground that he may locate, without interference on the part of the more boisterous element. When he returns at nightfall he has difficulty in finding his camp. The half-dozen brush-shacks and tents he left in the morning have suddenly multiplied into scores of tents and instead of a dozen rough prospectors he is likely to find hundreds

Ramsey as it was on August 1st.

Saloon and Newspaper Office.

covery the Ramsey boys, it is said, staked 150 claims, a thing legally possible but not altogether popular with others who in these days are eagerly watching the course of events in Nevada, and sleeping with one eye open. Everyone is on the alert and ready at a moment's notice

of men, many in 'boiled shirts' and 'store clothes,' and to see big automobiles wheeling clumsily over clumps of sage-brush and mounds of sand in the newly laid-out streets. Lots have gone up too, and the reports of rich strikes are heard and repeated on every side. Rough-

The Croppings of the Lucky Boy.

Sharpening a Drill.

to 'roll their blankets' and 'hit the trail,' for any new discovery that may be announced, no matter how far distant or how inaccessible. The past year has seen these new pioneers of the sagebrush State rushing hither and thither, across its deserts and mountains, acting promptly upon the slightest hint and sometimes on the merest rumor, of a new strike—fearing to be too late to secure a claim. The announcement of a new and rich find is the signal for a rush, as proved at Manhattan, Fairview, Buckskin, Seven Troughs, and others, and now Ramsey. However prompt the adventurous pilgrim—be he prospector, promoter, capitalist, or miner, he usually finds a townsite surveyed and staked, with lots temptingly ready for the investment of his spare cash—if he has any. The first building, or more often tent, to go up on the new townsite, is usually occupied as

looking old prospectors, miners, young fellows, seemingly store clerks, and even women, trudge into camp at nightfall, their pockets bulging with rock, some of which glitters with golden scales—of mica. Others, more wise, have the real thing, but make no haste to tell where they got it, and the excitement grows apace.

In the last days of July, Ramsey consisted of nearly 100 tents, three wooden buildings, and a few shacks built of brush, gunny sacks and old tin cans. Eight saloons aided in giving the place a metropolitan air. There was also the townsite office; two lodging-houses were contemplated and two restaurants were running night and day.

A writer on the ground says Ramsey has the biggest surface showing of any camp in the State. The veins of the district are big and strong, and they should go down

to great depths. One of the principal mining companies is the Ramsey Comstock. Several days ago 20 men began sinking a three-compartment shaft on the foot-wall of the Clark dike. Other shafts are being sunk as fast as possible. Another paragrapher in mining-camp phraseology writes: "A 20-in. streak of 'lousy' rich ore was found on the Brennan No. 2 Wednesday afternoon. Two pounds of ore was pounded up in a mortar, and retorted in a forge. The button weighed, rough, about \$6.50, and the assayer called it worth \$5.50 when he got it. The ore, therefore, at the place where the sample was taken is worth \$5,500 per ton."

In reading reports of this character the experienced mentally make the necessary discount as a sort of factor for safety in contemplating the over-enthusiasm of the news purveyor.

The accompanying illustrations give an idea of how Nevada's newest bonanza camp appeared about two weeks ago—it is no indication that it looks the same today, for it has had a chance to grow. One photograph shows the leading smith of the camp hard at work sharpening drills for prospectors. Another shows the office of the *Recorder*, the first newspaper in camp; a third illustrates only a portion of the lively town and the fourth gives a glimpse of the outcrop on the Lucky Boy claim.

The Essence of Crystalhood.

By HENRY M. HOWE.

*Assume a case of an initially perfect octahedron growing within a supersaturated solution. This octahedron is an organized being. Just as the surface of the intestine of an animal has the power of selecting, from the food presented to it, those substances required for the nourishment and the growth of the animal; the power of absorbing them, of assimilating them, and of rejecting all other matter; and just as the animal is sustained and grows through the selective, absorptive, assimilative and rejective power of the surface of its intestines, precisely so the crystal is armed with surfaces which have the power of selecting from the liquid in which it is immersed those molecules necessary to its growth (namely, molecules of matter like to itself) of absorbing those particles, of assimilating, that is, of polarizing and arranging them in a definite manner about its own structure; and finally of rejecting all foreign molecules. These faces thus have the power of selection, absorption, assimilation (that is, polarization and arrangement according to the structural needs of the organism) and rejection, exactly like the digestive and assimilating powers of the animal. Therefore I say that the crystal is an organized being, and that each crystal and detached crystalline grain is a separate and definite organization.

Suppose that our octahedron now keeps on growing, maintaining itself as a perfect octahedron, until it has grown to such a size that certain mechanical barriers, which it meets within the liquid, interfere with its further growth, and that further assimilation of matter is now unable, because of mechanical obstruction, to preserve the strict octahedral form. The form then which had been geometrical up to the time when this mechanical interference occurred now ceases to be geometrical. The object ceases to be a perfect octahedron, but does it cease to be a crystal? Are we to suppose that this organized being continues to be a crystal up to the moment of this outside mechanical interference, but that its further growth makes it cease to be a crystal? Is it not a more workable, a more reasonable scheme to hold that it remains a crystal, a deformed crystal, if you please, but still a crystal?

The Chinese woman's foot, deformed by restraint, remains a foot, a deformed foot, if you please, but still a foot.

Let us take another case. Our assumed perfect octahedron is removed and its angles are ground off slightly by mechanical means. If the grinding be very slight, it clearly remains a crystal. If we continue the grinding and deface it more and more without breaking it up, the question is: Do we make it a deformed and defaced crystal, or does it become, as the definition of Osmond implies, only a crystalline fragment? Let us assume that we grind off from the face of such a crystal 10% of its matter, enough to destroy its geometrical shape completely. Are the remaining 90% crystal or not? Should we not say that they are mutilated crystal, but still a crystal?

The case is essentially different from that of a statue, a cube or even a man, and really goes beyond even that of a book. Statue-hood and cube-hood depend exclusively upon external form and absolutely upon nothing else. I knock off the nose of a statue, and while the nose becomes a fragment, the body remains a statue. I proceed to knock off the arms and legs, and soon the statue ceases to be a statue and becomes a fragment; for, since statue-hood depends exclusively upon external form, relatively slight mutilation suffices to change a statue into a fragment. In the case of a man we carry the destruction much farther before manhood ceases, because manhood depends directly on life, and only indirectly upon external form as necessary to life; we can cut off both arms and both legs, and if life continues, the man remains a man, and is not a fragment merely.

In case of a book, however, mutilation can go much further without destroying book-hood. We tear the covers off a book and it remains a book, the very same book, because book-hood is not essentially dependent on external form. May we not say the same of a crystal—that external form is not essential to crystal-hood? In crystal-hood as in book-hood is not the interior far more essential than the external form? But is not the essentialness of internal organization true, *a fortiori* of crystal-hood, since the internal organization is the generator of outward symmetry, and will reproduce it, if the permissive condition, immersion in a suitable solution, exists?

ILLINOIS COALFIELDS.—The work of the State Geological Survey on the coalfields of Illinois is going rapidly forward. A large number of mines already have been visited, and careful samples taken for laboratory study; 160 such samples being now on hand. Director Bain recently visited the Livingston and La Salle county fields, preparatory to making careful surveys. J. A. Udden is now engaged in working out the faults near Peoria which have been such a constant source of annoyance and expense to operators in that vicinity. T. E. Savage is making a detailed study of the Springfield mines. J. J. Rutledge has taken up an investigation of the coals of the East St. Louis-Belleville area, and F. W. DeWolf is about to begin work in Saline and Gallatin counties. His work, as also that of David White, who is making collections of fossil plants throughout the field, is carried on by the U. S. Geological Survey in co-operation with that of the State. Topographic surveys preparatory to next season's work are being carried on near Harrisburg, Marion, Herrin, Murphysboro, Trenton, Edwardsville, Alton, and Tallua. A preliminary report upon the composition and character of Illinois coals is in press.

GOLD AMALGAM tightly squeezed usually contains about one-third gold, but there is a wide range in the composition of amalgam.

*The *Metallurgist*, Vol. V, 1902.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

APPARATUS FOR COOLING ORE.—No. 827,057; Henry F. Campbell, Melrose, Mass., and David H. Campbell and Thomas H. Smith, Denver, Colorado.

In an apparatus for conveying and cooling ore, the combination of units each consisting of a central conductor, a jacket inclosing the same, means for causing a circulation of water through said jacket, said central conductor having its ends provided with couplings, and said jacket consisting of a cylinder and circular nuts forming heads thereof connected together by annular screw-threaded rings.

ROASTING-FURNACE.—No. 825,326; Frank Klepetko, New York.

In a rabble apparatus, a hollow shaft divided into a series of compartments, hollow arms leading therefrom, means for introducing circulating medium into a compartment and into the arms leading therefrom, and conduits confined within the arms and establishing communication with a contiguous compartment through the partition-wall separating the compartments, whereby the cooling medium in the arms leading from any compartment is conveyed to the next compartment of the series.

APPARATUS FOR ELECTROSTATIC SEPARATION.—No. 827,116; Greenleaf W. Pickard, Amesbury, Massachusetts.

In an electrostatic separator, a source of electrical energy, electrodes, means to supply material thereto, means to heat the material before it reaches the electrode, and means to maintain a heated atmosphere about the electrode into contact with which the material is delivered.

ORE STAMP-MILL.—No. 828,126; Thomas E. Lambert, Butte, Montana.

A stamp mill, comprising one or more vertical stems, having shoes at the lower ends thereof, dies co-operating with the shoes, tappets on the stems, a shaft, and cams thereon for engaging with the tappets, coiled springs on the stems, upper and lower guides for the stems, and means for preventing contact of the coils of the springs with said stems, embodying flanged collars upon the tappets, and similar flanged collars at the upper ends of the springs, the said collars extending within upper and lower coils of the springs.

BLAST-FURNACE TUYERE.—No. 826,715; Thomas Evans, Great Falls, Montana.

1. A tuyere for blast-furnaces constructed with an opening in its bottom, a destructible disk normally closing said opening, a removable cap closing the outer end of the tuyere, said cap having an opening and a valve pivotally attached to the inside of the removable cap.

PROCESS OF REDUCING METALS.—No. 826,557; George L. Fogler, Pittsburg, Pennsylvania.

Continuous process of smelting ores which consists in forcing previously heated reducing gases into a reduction zone maintained in the ore, furnishing a supply of air insufficient to effect complete combustion around the gas supply whereby the incompletely burning gases reduce the ores, maintaining a partial vacuum above the charge whereby the gaseous products of the incomplete combustion and of the reduction expand into the upper portion of the charge and rapidly leave the reduction zone; continuously maintaining the reducing atmosphere in the furnace, drawing off the products of the smelting process and supplying fresh ore and flux from time to time.

ROCK-DRILL.—No. 828,684; John E. Sales, Wrangell, Alaska.

In a rock-drill, a car, a turn-table on the car, a main frame pivoted to the turn-table, means for adjusting said frame, a secondary frame pivoted in the main frame to swing in a plane at right angles to the plane of movement of the said frame, means for adjusting the secondary from a supporting-bar pivoted in the secondary frame to swing in a plane at right angles to the plane of movement of the secondary frame, said bar carrying guide-rods, means for adjusting the supporting-bar, a motor mounted to slide on the guide-rods of the supporting-bar, and means for sliding the motors on said bars.

Single-Lift Centrifugal Pumps.

Where, in stamp-milling or in concentration, water has to be used over again, the heaviest portion of its contained slime is deposited in the settling pond, the remaining water being, however, by no means clean. Such water, charged with fine mineral matter, makes much trouble with piston pumps, so that the centrifugal pump, containing, as it does, no valves, is especially valuable. These pumps, when single, make a lift no greater than 40 to 50 ft., and, in no case, should have to suck more than 20 ft. vertically. Fig. 1 represents such a pump, having a horizontal spindle or shaft, and Fig. 2 one having a vertical spindle, the pump itself being submerged.

Care must be taken, where, as in Fig. 1, a suction-pipe is used, that its joints and the stuffing-box gland around the shaft is perfectly air tight. To keep grit out of the stuffing-box a clear water-supply pipe under a head is often connected to it. This tends to keep grit out of the gland. The

Fig. 1. Kingsford Centrifugal Pump.

suction-pipe is fitted with a strainer and a foot-valve, which prevents the backward flow of the water when the pump comes to rest. The soundness of these joints is best tested by allowing the pump to stand for a short time with the pipes full of water, when, with a tight foot-valve, if leakage exists, it will show itself. When the water, which is to be raised, is below the centre of the pump-spindle, the pump must be charged or primed before it can deliver any water.

Fig. 2. Goulds Centrifugal Pump.

This is done by filling the suction-pipe and pump-case full of water while the pump is at rest, to, at least, as many inches above the top of the case as there are feet of suction below it. For this purpose a valve and funnel are fitted, either to the top of the casing, or to the foot of the stand-pipe. Often a pet-cock is placed at the top of the case to be opened in order to know whether the pump is running.

Where it is desired to raise the unsettled watery slime or pulp, this can be effected by submerging the pump. Its speed should then be so adjusted as to take the supply as it arrives without giving it time to settle, nor should it lift a

greater quantity than this, since then the sump would be emptied and the pump would become choked with slime, due to the fact that there would be no rush of water to carry off the thick mud.

Considering the rough work they are put to, and the gritty nature of the stuff handled, the wear is not excessive. The interior is lined with hard plates which are renewed, as they wear out, from spare parts kept in stock. The spindle and the runner, or impeller, also wear, and have to be renewed in the same way. Centrifugal pumps of this type give excellent service and are much in demand for cyanide plants and concentrators.

Trade Treatises.

THE WELLMAN-SEEVER-MORGAN Co., of Cleveland, Ohio, has issued circular No. H.O.-7, on high-grade geared hoisting engines. As usual with its publications, it is beautifully printed and handsomely illustrated.

THE HENDRIE & BOLTHOFF MANUFACTURING & SUPPLY Co., of Denver, Colo., has issued a little pamphlet descriptive of the hydro-electric power plant of the Nevada Power Mining & Milling Co., on Bishop creek, Cal. The details are interesting and instructive.

Mine and Quarry for August, issued by the SULLIVAN MACHINERY Co., of Chicago, contains the usual amount of readable and valuable practical information. The features of the August number are The Gunnison Colorado Tunnel; Channeling in New York City, and Quarrying Sandstone at Amherst, Ohio.

THE CYCLONE DRILL Co., of Oroville, Ohio, has issued a book descriptive of its machinery and methods of operating. The Cyclone drill is a hollow-rod device used in sinking wells and in prospecting for minerals in either solid rock or fragmental material such as wash gravel.

Commercial Paragraphs.

ROBERT H. RICHARDS has returned to Boston, after a visit to Denver and Chicago, where he has made arrangements for manufacturing his classifiers.

THE DE LA VERGNE MACHINE Co., of East 138th St., New York, reports nine recent orders received for Hornsby-Akroyd oil engines, aggregating 245 horsepower.

J. M. BROUCHER has resigned from the employ of the Brownell Co. of Dayton, Ohio, to act as assistant general manager of Sales for the Atlas Engine Works of Indianapolis.

M. P. BOSS has associated himself with the Norris K. Davis Machine Co., 7th and Harrison St., San Francisco, who will manufacture his standard crushing and milling machinery.

HOWARD E. TROUTMAN has resigned from the Buckeye Engineering Co. to accept the sales management of the Corliss and high-speed engine department of the Atlas Engine Works of Indianapolis, Indiana.

THE annual report of the WESTINGHOUSE ELECTRIC & MANUFACTURING Co. for the year ending March 31, 1906, shows the enormous volume of business done by this enterprising firm. It employs directly in the conduct of its business nearly 15,000 people, not including the selling organization. The report shows the business done by this concern now amounts to about \$35,000,000 annually, with proportional profit, dividends for six years ending March 31, 1906, having been \$9,922,069 with a surplus on hand of over \$11,000,000.

THE BUFFALO FORGE Co., of Buffalo, N. Y., has recently closed a large contract with the Bethlehem Steel Co. for forced draft equipment, consisting of six fans and engines (direct-connected) to drive the same. There is included in the contract, provision for complete accessories in the line of dampers, speed regulating valves, piping, ducts, etc. They report the contract as secured, solely on the engineering merits of the apparatus offered, several other companies submitting proposals with lower bids.

Editorial.

THE FATEFUL 16th of September has come and gone without a revolution in Mexico. It may be that the orders of President Diaz to close all the saloons during the *fiesta* dried the enthusiasm of the gentlemen to whom Mr. W. R. Hearst has given so much needless notoriety; it may be that the *rurales* put the fear of the Lord into the *peones*; in any event, it is a matter for satisfaction that the date has passed without any trouble.

AN UNEXPECTED ASSOCIATION of ideas is provoked by the contribution of Mr. A. E. Drucker on 'Tube-Milling in Korea.' The hermit kingdom has stood so long for the type of all that is unprogressive that it upsets our notions to learn of a new development in cyanidation as originating there. However, the new ideas are not indigenous; they come from the Americans who have made the Oriental mines at Taracol one of the most successful enterprises in eastern Asia. The use of cyanide solution in the tube-mill parallels the use of cyanide in battery water. Mr. Drucker appears to have made a success and it remains to be seen whether the method will survive. In stamp-milling, the use of cyanide in the battery is now uncommon. In many cases it has been found that the chemical exerts a selective solvent action on the gold in the amalgam and actually precipitates silver on the copper plates; if the solution exceeds 0.005 KCy it is apt to attack the copper and give the plates a bad surface.

THE WRITER on 'A Confusion of Terms' has done well in hiding his identity under a pseudonym, for his vigorous onslaught is calculated to cause trouble. His objection to the use of certain appellations is in line with the discussion on 'Who Is a Mining Engineer?'—a question concerning which we hope to say something when others have expressed their views. As to 'mining man,' 'cyanide man,' and the rest of it, the choice of terms must remain a question of taste and the want of it—especially the latter. A French proverb says: Each to his taste and the merchant sells everything. It is not for us to teach the public in matters like these. Among professional men there is a dislike of the term 'expert,' because it has been stolen by masqueraders in the serio-comedy of mine promotion. 'Mining man' covers a multitude of energetic citizens and has ceased to be distinctive. As to 'cyanide man,' that certainly is no synonym for metallurgist, and so long as it describes the operator of the cyanide annex, there is no harm done. People chose their own labels. We are reminded of the man who, having acquired the title of 'professor' by no academic route, explained that when all was said and done, a professor was a man who professed to be—a professor. The meeting adjourned.

Ore Stealing.

Provoked by the hasty criticism of a visiting journalist, the Chamber of Mines of Western Australia has placed on record its views on the methods applied to suppress gold stealing and the illicit trade incidental to such thefts. The rich mines at Kalgoorlie have lost heavily from this cause, as was the case at Cripple Creek when much specimen ore was being mined; it is one of the penalties incidental to the exploitation of lodes containing visible gold or those lustrous tellurides that attract a covetous hand. Despite a diminution in the issue of gold-dealers' licenses, the passage of laws containing severe provisions against both thief and receiver, the vigilance of the police, and the precautions of the mine management, this evil has persisted in serious proportions. Two factors have prevented the suppression of stealing; the first is the notion even among miners who are otherwise honest that there is no harm in annexing a specimen; the second is the spurious sentimentality of the public, which will condone the offense and, in cases of prosecution, is inclined to side with the accused, so that a perverting influence is exerted on magistrates and juries. This general tolerance, to be noticed in most mining camps, originates in self-interest. Those who make money by the illicit traffic, spend it freely, especially in the saloons and gambling houses. They spend it on the spot and help local trade. Hence the undercurrent of sympathy with both the thief and the receiver. At Kalgoorlie, as at Cripple Creek, there have been many perversions of justice; again and again prosecution has been brought and the theft fully demonstrated, and yet the accused has escaped through a legal technicality, the disagreement of the jury, or the absconding of the culprit from a bail disproportioned to the sum involved. At Cripple Creek we remember a judge who decided that ore stealing was not petty larceny, because mineral was real estate! Finally, in both the mining districts mentioned, it became apparent that the root of the evil lay in the existence of a ring of receivers who masqueraded as assayers; in Colorado they are called 'fences'—an old term for receivers of stolen goods. At Cripple Creek these establishments were dynamited—by persons unknown—during the troublous days of labor disturbances. This was a wrong way of getting rid of them, because dynamiting is worse than ore stealing. At Kalgoorlie the withdrawal of gold-buyers' licenses and the activity of the police were largely successful in driving away the dealers in stolen ore, and with their withdrawal the illicit trade languished. But it appears to have revived through the leniency of the magistrates, who levy small fines instead of prescribing imprisonment. Even the penalty of six months in jail will not deter the confirmed thief, who will risk it for big plunder. So the Chamber of Mines asks for heavier punishments, denial of bail, and the issue of search warrants. As it is now, legal proof of the receipt of stolen mineral or pilfered gold-slime from the zinc-boxes in the cyanide plant is difficult to get, even when men are known to be doing a business in these things. To circumvent the law, it is the practice at Kalgoorlie to use two devices—the adulterated purchase

and the dummy lease. Small lots of slag, furnace products, or dump ore are bought, with their value unspecified, and a receipt is obtained. This truck is mixed with specimen ore, concentrate, or gold-slime, and the mixture is put through the pretense of metallurgical treatment. The other scheme is to get a lease on a mining claim and add the stolen stuff to worthless ore, the result being credited to a mine from which it did not come. The Chamber of Mines demands that all reduction works and treatment plants be licensed, and compelled to keep accounts recording their transactions, these to be open to the inspection of detective officers. Finally, it is claimed that a special branch of the police department should be organized to attend solely to gold-stealing. All of which is, in the main, reasonable. Any restrictions or regulations that do not hinder honest men ought to be welcomed. One of the worst aspects of ore stealing is the development of queer notions of property and the palliation of crime. If this form of larceny is made increasingly difficult, the whole standard of honesty in mining communities will be the better for it.

Change-Houses.

There is reason to believe that the strike at Goldfield was due, not to the ostensible cause, but to the recognition on the part of the mine owners and lessees that the stealing of ore is depriving them of an undue proportion of their profits. 'High-grading' is the term applied to the larceny of gold ore; it is a term that was brought to Nevada from Cripple Creek, whence also came some of the restless spirits who are never happy unless there is a quarrel between those who provide the capital for mining operations on the one hand and those who supply the equally necessary muscle on the other. It has become obvious to the men who are exploiting the wonderfully rich veins of this new gold district that a stop must be put to the pilfering that is rampant throughout the camp and that, to do this, change-houses must be built and stripping made compulsory, as in other localities. No honest miner will object. It should be required of every company that it provide a comfortable and a sanitary building wherein the men can change their clothes on coming from underground. To discard clothing that is wet either with perspiration or mine water, to have a good wash or a shower bath, to dry the discarded garments and to put on street clothes, is surely an obviously sensible proceeding. For lack of such care, many miners get pneumonia. And if the working clothes are discarded in one room and the street clothes donned in another, there is a simple safeguard against stealing, while at the same time it affords a comfortable separation between those who are begrimed with the marks of toil and those about to go home in the garb of ordinary citizens. We know that the change-house has caused trouble more than once, but that has been when it threatened to stop the stealing of ore. At most mines, especially where the temperature at the surface differs much from that obtaining underground, the men recognize the need of such a convenience. It has the merit of serving two purposes—health and honesty.

By the Way.

DUTY ON ZINC ORE.—The Board of United States General Appraisers gave a second hearing recently in the test case brought by the Treasury Department in order to determine the classification of zinc ore for duty. The first hearing was given to the importers, represented chiefly by the New Jersey Zinc Co., and the second session was occupied by the representatives of mine-owners. The question was whether zinc ore is a metallic mineral substance subject to a duty of 20%, or whether it can be admitted free under the tariff provision for 'calamine.' It is a good example of the curious distinctions set up by those who frame tariffs. Axel O. Ihlseng, John R. Holmes, T. C. Molloy, and other witnesses united, in behalf of the mine-owners, in testifying that the zinc blende is a metallic mineral substance—which, at this distance, seems fairly obvious. The smelting interests claim that in the United States there is not enough zinc ore being produced to keep the furnaces running and that supplies must be secured from Mexico and British Columbia. The mine-owners assert that the smelters are using the spelter duty of 1½ cents per pound to force down the price of domestic zinc ore. Therefore they ask a low duty or a free entry for such ores, quoting the tariff provision for calamine. The case is under advisement.

THE COST OF LIVING.—The Bureau of Labor of the Department of Commerce and Labor, Washington, D. C., gives in its Bulletin No. 65, for July, 1906, an exhaustive presentation of the results of an investigation into wages and hours of labor in 1905 in the principal manufacturing and mechanical industries of the United States, taking identical establishments with those investigated in 1904. A summary of the results is as follows:

In 1905 the average wages per hour in the principal manufacturing and mechanical industries of the country were 1.6% higher than in 1904; the average hours of labor per week remained the same as in 1904, and 6.3% more persons were employed in the establishments investigated. As there was no reduction in the average hours of labor per week, the average weekly earnings per employee were 1.6% higher than in 1904. As there was an increase in the number of employees as well as in the weekly earnings per employee, there was a considerable increase in the weekly earnings of all employees, or, in other words, in the amount of the weekly payroll. This increase was 8% in the establishments investigated.

The retail prices of food, due weight being given to the quantity and cost of the different commodities consumed, were 0.6% higher in 1905 than in 1904. As the average wages per hour increased more than the retail prices of food, the purchasing power of wages increased. In 1905 the purchasing power of both hourly and weekly wages was 1% higher than in 1904, or, expressed in other words, an hour's wages in 1905 would purchase 1% more food than an hour's wages in 1904.

The average wages per hour in 1905 were 18.9% higher than the average for the ten-year period from 1890 to 1899, inclusive. The number of employees was 33.6% greater, and the average hours of labor per week were 4.1% lower. The average earnings per week in 1905 were 14% higher than the average earnings per week during the ten years from 1890 to 1899. The aggregate weekly earnings of all employees—that is, the total amount of the payrolls—were 52.3% higher in 1905 than the average during the 10-year period named.

The retail price of the principal articles of food, weighted according to family consumption of the various articles, was 12.4% higher in 1905 than was the average price for the ten years from 1890 to 1899. Compared with the

average for the same 10-year period, the purchasing power of an hour's wages in 1905 was 5.8% greater, and of a week's wages 1.4% greater, the increase in purchasing power of weekly wages being less than the increase in purchasing power of hourly wages because of the reduction of the hours of labor during the period.

The average wages per hour in 1905 were 21.5% higher than in 1894, the year of lowest wages during the period covered, and weekly earnings were 16.7% higher. The purchasing power of an hour's wages was greater in 1905 than in any other year covered by this investigation, being 7.7% greater than in 1894, the year of lowest wages, and 1.3% greater than in 1896, the year of lowest retail prices. The purchasing power of a week's wages in 1905 was 3.5% greater than in 1894, but 2.7% less than in 1896.
